5. The official preparations of arsenic, with their doses, are: Arseni trioxidum, gr. 1/30; Liquor acidi arsenosi, ♏vij; Arseni iodidum, gr. 1/20; Sodii arsenas, gr. 1/6; Sodii arsenas exsiccatus, gr. 1/20; Liquor potassii arsenitis, ♏vij; Liquor sodii arsenatis, ♏v; Liquor arseni et hydrargyri iodidi, ♏vij.

The official antidote for arsenical poisoning is freshly prepared solution of ferric hydroxide. Mix 40 parts of solution of ferric sulphate with 125 parts of water and keep it in a large well-stoppered bottle. Rub ten parts of magnesium oxide with some cold water to a thin smooth mixture, transfer it to a bottle holding about a liter, and then fill with water to about 750 c.c. When required for use, shake the magnesium mixture, add it gradually to the ferric sulphate solution, and shake them together till the mixture is uniform.

6. Aromatic sulphuric acid, ♏xv; tartaric acid, gr. vij; salicylic acid, gr. vij; diluted phosphoric acid, ♏xxx; diluted nitro-hydrochloric acid, ♏xv.

7. Cantharides, from Spanish flies; ichthyol, from fossil remains of fish; cod liver oil, from the Gadus morrhua.

8. Hydrargyrum cum creta, gr. iv; massa hydrargyri, gr. iv; hydrargyri chloridum mite, gr. j; liquor arseni et hydrargyri iodidi, ♏jss; hydrargyri chloridum corrosivum, gr. 1/20; pilulæ catharticæ compositæ, 2 pills.

9. Pulvis acetanilidi compositus (acetanilide 70, caffeine 10, sodium bicarbonate 20), gr. vijss; Pulvis cretæ compositus (prepared chalk 30, acacia 20, sugar 50), gr. xxx; Pulvis ipecacuanhæ et opii (ipecac 10, opium 10, sugar of milk, 80), gr. vijss; Pulvis jalapæ compositus (jalap 35, potassium bitartrate 65), gr. xxx; Pulvis rhei compositus (rhubarb 25, magnesium oxide 65, ginger 10), gr. xxx.

10. ℞. Tincturæ gentianæ compositæ, ʒij.
Tincturæ nucis vomicæ, ʒiij.
Sodii bicarbonatis, ʒiij.
Elixiris simplicis, q.s. ad ʒiv. M.
Sig.: One teaspoonful in water, t.i.d.
℞. Ferri reducti, ʒss.
Arseni trioxidi, gr. 3/5.
Strychninæ sulphatis, gr. ss.
Quininæ sulphatis, gr. xv. M.
Fiat massa in pillulas no. xxx dividenda.
Sig.: Take one pill after each meal.
℞. Tincturæ digitalis, ʒiij.
Potassii nitratis, ʒiij.
Fluidextracti buchu, ʒiij.
Elixiris simplicis, q.s. ad ʒiv. M.
Sig.: One teaspoonful, in water, q. 3. L.
℞. Pepsini, ʒiij.
Bismuthi subnitratis, ʒiij.
Tincturæ opii camphoratæ, ʒj.
Aquæ destillatæ, q.s. ad ʒiv. M.
Sig.: One teaspoonful t.i.d.

THERAPEUTICS.

1. *Five antispasmodics:* Amyl nitrite, aconite, camphor, valerian, ipecac. Used to prevent or alleviate muscular spasms.

2. ℞. Extracti aconiti, gr. ijss.
Pulveris ipecacuanhæ et opii, gr. xij.
Quininæ sulphatis, gr. xxxvj.
Acetphenetidini, 5j. M.
Ft. in capsulas no. xxiv.
Sig.: Take two every three hours.
For use at beginning of influenza.
℞. Ferri et quininæ citratis, 5j.
Aquæ destillatæ.
Tincturæ nucis vomicæ, āā5ij.
Syrupi hypophosphitum q.s. ad 5iij. M.
Sig.: One teaspoonful before meals.
Used as a tonic.

3. "*An antitoxic serum* is a blood serum containing antitoxin, produced therein by the cells of the organism as a result of the repeated injection of a toxin into the tissues of the animal from which the serum is taken." *Diseases most amenable to serum therapy* are: Diphtheria, tetanus, streptococcus infection, snake poison, and bubonic plague.

"Diphtheria antitoxin is obtained from the horse, the animal having been rendered artificially immune by repeated injections extending over a period of several months of gradually increasing quantities of the strongest diphtheria toxin. As the bacilli themselves are not injected, the horse does not become infected with diphtheria, but he gradually acquires a tolerance for the toxins of the disease and developed in his blood a substance (antitoxin) which has the power to neutralize those toxins. At the proper time, when it is thought that his blood has acquired the requisite degree of potency, the animal is bled, and the serum—the part of the blood containing the antitoxin—is carefully separated from the clot, filtered, and standardized. The last procedure is accomplished by determining the quantity of antitoxin serum required to offset the effects of the minimum quantity of toxin necessary to kill a guinea-pig in a definite time. The strength of the antitoxin is measured in units, a unit containing the amount of antitoxin required to save the life of a guinea-pig which has been injected with 100 fatal doses of toxin."—(Stevens' *Materia Medica.*)

And see French's "Practice of Medicine" (1910), page 197.

4. Opium. *Therapeutic uses:* As an anodyne, a hemostatic, in inflammations, as an expectorant, in diarrhea, in alcoholism, manias, and diabetes, as an antispasmodic, in insomnia, and as a diaphoretic.

Symptoms of poisoning: "At first there is usually a period of excitation, marked by restlessness, great physical activity, loquacity, and hallucinations. The patient then becomes weary, dull, and drowsy; he yields to the desire for sleep, from which at first he may be roused. The lips are livid, the face pale, the pupils contracted, and the surface bathed in perspiration. The condition of somnolence rapidly passes into narcosis. The patient cannot be roused, and lies motionless and senseless, with completely relaxed muscles. The pulse, at first full and strong, becomes feeble, slow, irregular, and easily compressible; the respiration slow, shallow, stertorous, and accompanied by mucous râles. The patient rapidly becomes comatose, and, in fatal cases, dies in from forty-five minutes to fifty-six hours, usually in from twelve to eighteen hours. In cases of recovery after the stage of narcosis, the pulse and respiration gradually return to the normal, and the condition of coma passes into one of deep sleep, lasting twenty-four to thirty-six hours."—(Witthaus' *Essentials of Chemistry and Toxicology.*)

Strychnine. *Therapeutic indications:* As a general tonic or bitter; in indigestion, cardiac depression, impaired peristalsis, pneumonia, phthisis, amenorrhea, dysmenorrhea, impotence, some forms of paralysis, chorea, epilepsy, neuralgia, alcoholism, and urinary incontinence.

Symptoms of poisoning: "A sense of suffocation, thirst, tetanic spasms, usually opisthotonos, sometimes emprosthotonos, occasionally vomiting, contraction of the pupils during the spasms, and death, either by asphyxia during a paroxysm or by exhaustion during a remission. The symptoms appear in from a few minutes to an hour after taking the poison, usually in less than twenty minutes; and death in from five minutes to six hours, usually within two hours."

5. See Rose and Carless' "Surgery" (1908), page 356.

6. Colchicum. *Physiological action:* It causes salivation, irritation of the gastrointestinal tract, increased elimination of uric acid, and collapse; it is also a diuretic. *Therapeutic uses:* Chiefly for gout; also in neuralgia, headache, dyspepsia, and bronchitis in gouty people.

7. Digitalis. *Physiological action:* It is a gastrointestinal irritant, it slows the rate of the heart, prolongs diastole, increases the force of the heart, it contracts the blood-vessels, and causes a rise in blood pressure, it also acts as a diuretic.

Therapeutic use: Digitalis is indicated in diseases of the heart: (1) when the heart action is rapid and feeble, with low arterial tension; (2) in mitral lesions when compensation has begun to fail; (3) in nonvalvular cardiac affections; (4) in irritable heart, due to nerve exhaustion. Digitalis is contraindicated in diseases of the heart: (1) in aortic lesions when uncombined with mitral lesions; (2) when the heart action is strong, and arterial tension high. Digitalis is also a diuretic; and it is also used in some forms of nephritis, exophthalmic goiter, pneumonia, chronic bronchitis, etc.

Overdose or constant use will cause irregularity of the heart, headache, vomiting; and hobbling dicrotic pulse, particularly when the patient changes from the recumbent to a sitting posture.

8. See French's "Practice of Medicine" (1910), page 311; or Osler's "Practice of Medicine" (1909), page 123.

9. *Cardiac sedatives* lessen the force and frequency of the heart's action; aconite, antimony, and chloral. *Cardiac stimulants* increase the force and frequency of the pulse in depressed conditions of the cardiac apparatus; alcohol, ammonia, and nitroglycerin. *Cardiac tonics* stimulate the heart muscle and strengthen its contractions; digitalis, sparteine, and caffeine.

10. *Antagonists* "are agents which directly oppose each other in some or all of their physiological actions, and therefore may be used, one against the other, in a case of poisoning by either, to *counteract* its effect upon the organism, after it has been absorbed, and when, therefore, the time for an antidote has passed. Antagonistic action takes place in the blood and tissues, and is applicable almost entirely to vegetable poisons."

Antidotes "are agents which act upon poisons in such a manner as to alter their composition, rendering them more or less innocuous and so *preventing* their toxic action being exerted upon the organism. Antidotal action takes place in the alimentary canal, upon such portion of the poison as is unabsorbed, and is applicable to vegetable as well as to mineral poisons."—(Potter's *Materia Medica.*)

PATHOLOGY.

1. The object is first placed in some fixing fluid, then it is washed, then hardened by immersion in alcohol, then treated with some clearing agent, then placed in paraffin; it is then ready for the section cutter. After the sections are cut the next process is staining, after which the object is ready for examination.

2. See French's "Practice of Medicine" (1910), pages 1257, etc.

3. To demonstrate the existence of *tubercle bacilli* in the sputum: The sputum must be recent, free from particles of food or other foreign matter; select a cheesy-looking nodule and smear it on a slide, making the smear as thin as possible. Then cover it with some carbolfuchsin and let it steam over a small flame for about two minutes, care being taken that it does not boil. Wash it thoroughly in water and then decolorize by immersing it in a solution of any dilute mineral acid for about a minute. Then make a contrast stain with solution of Loeffler's methylene blue for about a minute; wash it again and examine with oil immersion lens. The tubercle bacilli will appear as thin red rods, while all other bacteria will appear blue.

4. See French's "Practice of Medicine" (1910), page 500; or Osler's "Practice of Medicine" (1909), page 40.

5. To *differentiate human and bovine serum:* To a small portion of each add a little human blood. The one producing the greatest laking is bovine. Control, by taking another small portion of each and adding fresh bovine blood. The serum producing most prompt laking is human.

Anaphylaxis is a condition of supersensitization induced by the injection of a serum. It is the opposite of prophylaxis, and in place of rendering the person injected immune, the serum has made him particularly susceptible.

Alarming symptoms which have been observed are: Heart failure, collapse, convulsions, coma.

6. See French's "Practice of Medicine" (1910), pages 72 and 86; or Osler's "Practice of Medicine" (1910), page 67.

7. See French's "Practice of Medicine" (1910), pages 342 and 364; or Osler's "Practice of Medicine" (1910), page 295.

8. See French's "Practice of Medicine" (1910), pages 182 and 190; or Osler's "Practice of Medicine" (1910), page 203.

9. See French's "Practice of Medicine" (1910), pages 639 to 644; or Osler's "Practice of Medicine" (1910), pages 847 to 852.

10. See French's "Practice of Medicine" (1910), page 1108; or Osler's "Practice of Medicine" (1910), pages 967, etc.

PRACTICE.

1. *Enteroptosis* is prolapse of the intestines. *Ludwig's angina* is acute purulent cellulitis of the submaxillary region. *Purpura* is a disease or condition characterized by patches of extravasated blood in the skin or mucous membranes. *Myxedema* is a condition in which the subcutaneous tissues (chiefly of face and hands) are infiltrated with a mucous fluid; it does not pit on pressure. *Angina pectoris,* see French's "Practice of Medicine" (1910), page 634; or Osler's "Practice of Medicine" (1909), page 839.

2. See French's "Practice of Medicine" (1910), pages 457, 509, and 868; or Osler's "Practice of Medicine" (1909), pages 255, 38, and 548. *Empyema* is pus in the pleural cavity, or purulent pleurisy. *Dysphagia* is difficulty in swallowing; it may be caused by inflammations of tongue, mouth, tonsils, pharynx; paralysis of pharynx or palate; retropharyngeal abscess; ulceration of larynx; inflammation or stricture of esophagus; pressure of aneurysm, thyroid, or tumors.

3. *Measles:* Period of incubation, ten to twelve days. Stage of invasion, four days. Character of eruption, small dark red papules with crescentic borders, beginning on face and rapidly spreading over entire body; desquamation is bramy. The eruption is darker, less uniform, more shotty; the temperature is lower, pulse slower, the tongue is not of the "strawberry" type; coryza, coughing, and sneezing may be present; Koplik's spots are present.

Scarlet fever: Period of incubation, from a few hours to seven days. Stage of invasion, twenty-four hours. Character of eruption, a scarlet punctate rash, beginning on neck and chest, then covering face and body; desquamation is scaly or in flakes. The eruption is brighter, is on a red background, punctiform, and is more uniform; the temperature is higher, the pulse quicker; the tongue is of the "strawberry" type, the lymphatics in the neck may be swollen, and there is sore throat; Koplik's spots are absent.

4. See French's "Practice of Medicine" (1910), pages 171 and 713; or Osler's "Practice of Medicine" (1909), pages 188 and 651.

5.

EPILEPSY.	HYSTERIA.
1. No apparent cause.	1. Cause, emotional.
2. Sudden and rapid onset.	2. Onset gradual, usually after some mental excitement.
3. Aura generally present.	3. Globus hystericus or palpitation.
4. Consciousness lost.	4. Consciousness generally preserved.
5. Pupils generally dilated.	5. Pupils normal.
6. Tongue often bitten.	6. Tongue never bitten.
7. Patient very liable to hurt himself.	7. Patient not liable to hurt himself; may injure others.
8. May be involuntary bladder and bowel discharges.	8. Never.
9. Of short duration.	9. Duration longer.

6. See French's "Practice of Medicine" (1910), pages 109 and 81; or Osler's "Practice of Medicine" (1909), pages 99 and 71.

7. See French's "Practice of Medicine" (1910), pages 397 and 396; or Osler's "Practice of Medicine" (1909), pages 352 and 351.

8. See French's "Practice of Medicine" (1910), pages 916, etc.; or Osler's "Practice of Medicine" (1909), pages 692, etc.

9. Appendicitis; diseases of the cecum and ovary.

10. See French's "Practice of Medicine" (1910), page 765; or Osler's "Practice of Medicine" (1909), page 473.

OBSTETRICS.

1. See Williams' "Obstetrics" (1909), page 303.

2. See Williams' "Obstetrics" (1909), pages 321 and 662; or Hirst's "Obstetrics" (1909), page 320.

3. See Williams' "Obstetrics" (1909), pages 373 and 376; or Hirst's "Obstetrics" (1909), page 797.

4. *Indications for the use of forceps* are: (1) *Forces at fault:* Inertia uteri in the presence of conditions likely to jeopardize the interests of mother or child. (*a*) Impending exhaustion; (*b*) arrest of head, from feeble pains. (2) *Passages at fault.* Moderate narrowing, 3¼ to 3¾ inches, true conjugate; moderate obstruction in the soft parts. (3) *Passenger at fault:* A. Dystocia due to (*a*) occipito-posterior; (*b*) mentoanterior face; (*c*) breech arrested in cavity. B. Evidence of fetal exhaustion (pulse above 160 or below 100 per minute). (4) *Accidental complications:* Hemorrhage; prolapse funis; eclampsia. All acute or chronic diseases or complications in which immediate delivery is required in the interest of mother or child, or both. *Contraindications:* Mechanical obstruction in the parturient canal; incomplete dilatation of the os; non-rupture of membranes; non-engagement of the presenting part; the fetal head being too large or too small; distended bladder or rectum.

And see Williams' "Obstetrics" (1909), pages 400 and 419; or Hirst's "Obstetrics" (1909), pages 811 and 824.

5. See Williams' "Obstetrics" (1909), page 287; or Hirst's "Obstetrics" (1909), page 419.

6. See Williams' "Obstetrics" (1909), page 298; or Hirst's "Obstetrics" (1909), pages 343 and 434.

7. *Hemorrhages during labor:* Caused by (1) placenta previa; (2) premature separation of a normally situated placenta; (3) relaxation of the uterus; (4) laceration of the cervix; (5) rupture or inversion of the uterus.

Hemorrhages after labor: Caused by (1) retained secundines; (2) displaced uterus; (3) displaced thrombi; (4) fibroid tumors; (5) hypertrophied decidua; (6) carcinoma.—(From Gould and Pyle's *Cyclopedia.*)

8. *Indications for amputation of the cervix uteri:* "Certain cases of cancer of the cervix, of ectropium of the cervix accompanied by profuse leucorrhea and by reflex nervous disturbances, cervical endometritis with cystic degeneration from occlusion of the ducts of the Nabothian glands, of laceration of the cervix, of hypertrophy of the infravaginal cervix; and cases of procidentia."—(From Kelly and Noble's *Gynecology.*) *Method:* "The cervix is thoroughly exposed by the introduction of the bill of a large speculum; with the sound the operator determines the position of the cervical canal and estimates the mobility of the uterus; by means of the vesical sound the precise relation of the bladder to the cervix is ascertained. The cervix is firmly grasped with a stout volsella and drawn down; with a scalpel the surgeon transversely divides the mucous membrane on the anterior wall of the cervix as high up as the bladder permits; the assistant keeps him informed of the position of the bladder by retaining the sound in the lowest part of the vesical cavity. Having divided the mucous membrane, the bladder is easily detached from the cervix by the handle of the scalpel. The knife is then carried through the mucous membrane on the sides and posterior aspect of the cervix. The next step is to secure the uterine arteries as they run to the sides of the cervix near the spot where the vaginal mucous membrane is reflected on to it. When the bladder is detached and held apart from the cervix by a retractor, while the cervix is drawn down by the volsella, the artery may be seen, and is easily secured. It is well to secure it as close to the center as possible in order to avoid the ureter. Having secured the artery on each side, the cervix may be amputated with a scapel or with scissors. When the uterine arteries are deliberately exposed and secured there is no bleeding from the stump, but a small artery here and there in the cut edge of the vaginal mucous membrane may require to be seized or ligatured. The vagina is then douched, dried, and tamponed, and the patient returned to bed."—Sutton and Giles' *Diseases of Women.*)

9. *Causes:* Gonorrhea, tuberculosis, sepsis; and see Williams' "Obstetrics" (1909), pages 864, 877, and 884; or Hirst's "Obstetrics" (1909), pages 744 and 756.

10. Sepsis, hemorrhage, perforation of uterus, abortion, and inflammation of uterus or adnexa.

SURGERY.

1. See French's "Practice of Medicine" (1910), pages 87 and 118; or Osler's "Practice of Medicine" (1909), pages 82 and 103.

2. See Rose and Carless' "Surgery" (1908), page 956; or Da Costa's "Surgery" (1908), page 1236.

3. See Rose and Carless' "Surgery" (1908), pages 921, 914, and 915; or Da Costa's "Surgery" (1908), pages 771 and 770.

Laryngotomy is indicated in sudden asphyxia, such as foreign body, or edema or spasm of the larynx, or as a preliminary to certain operations on the throat or mouth. *Laryngo-tracheotomy* is indicated in laryngeal obstruction. *Intubation* is indicated in membranous and edematous laryngitis (as a substitute for tracheotomy).

4. ACUTE CATARRHAL CONJUNCTIVITIS. *Symptoms:* Hyperemia, lacrimation, epiphora, discharge, photophobia, sensa-

tion of sand in the eye; symptoms are worse in evening. *Treatment:* Remove cause, if possible; use astringent and antiseptic washes; anoint the lids with vaseline; alum, tannic acid, zinc sulphate, or silver nitrate have all been recommended. When it becomes contagious its common name is "pink-eye."

5. See Rose and Carless' "Surgery" (1908), pages 1248, 1249, and 1231; or Da Costa's "Surgery" (1908), pages 1181 and 1178.

*No reciprocity recognized by these States.

†Applicants should in every case write to the secretary for all the details regarding the examination in any particular State.

Parotitis and the Puerperium.—Fischer describes a case of unilateral parotitis occurring twenty-four hours after a spontaneous delivery in a primipara. He regards this as of the same nature as postoperative parotitis, of traumatic origin, in which the fingers of the anesthetist force the jaws apart, causing traumatism. In his patient the author attributes the traumatism to the cries accompanying the labor pains.—*Zentralblatt für Gynäkologie.*

Desiccated Liver Extract in Diabetes and Chronic Gastrointestinal Autointoxication.—Mulot states that if this substance, even on extended use, fails to cause the disappearance of the sugar in certain cases of diabetes it seems of such positive value in giving better and more permanent results in chronic gastrointestinal autointoxications that it deserves to find a permanent place in therapeutics.—*Long Island Medical Journal.*

Medical Items.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week of February 4, 1911.

	Cases	Deaths
Tuberculosis Pulmonalis	579	172
Diphtheria	358	27
Measles	399	15
Scarlet Fever	469	19
Smallpox	—	—
Varicella	135	—
Typhoid Fever	35	6
Whooping Cough	88	5
Cerebrospinal Meningitis	5	4
Malarial Fever	—	—
Totals	2,068	248

Dairy Inspection.—Moak states that with milk no less than with water can one do most toward insuring a clean, wholesome supply by watching and guarding its source. Adequate dairy inspection is the means. Sooner or later it must be uniformly done throughout the dairy industry.—*Long Island Medical Journal.*

Effect of Influenza on the Heart.—Cornwall states that the signs and symptoms referable to the heart which may be found in influenza are weakness, irregularity, or intermittency of the heart's action or the production of hemisystoles, rapid action, bradycardia, softening of the heart sounds, equalization of the two sounds at the apex, blunting of the pulse wave.—*Long Island Medical Journal.*

Influence of the Spleen upon Gastric Digestion.—O. Gross found that following extirpation of the spleen the secretion of pepsin disappears almost completely and then slowly attains its normal height. At the same time there is a lymphocytosis which, parallel with the increasing pepsin-content, falls to the normal level.—*Zeitschrift für experimentelle Pathologie und Therapie.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended February 3, 1911.

THE PROPER MANAGEMENT OF FOUNDLINGS AND NEGLECTED INFANTS.*

BY HENRY DWIGHT CHAPIN, M.D.,

NEW YORK.

THE subject of infant mortality is just now very much in the air. It seems to be coming home to the professional and lay conscience and understanding that a needlessly large mortality exists in this helpless class of the community. This heavy mortality is nothing new, as it has existed since the dawn of history, but it has recently attracted more attention than usual and there is a stirring of effort for better things. Just as in tuberculosis, the heavy death toll has been exacted for centuries, until a concerted and continuous effort has only recently been made to check its ravages, so there has been a belated struggle to stop this largely preventable waste of infant life. It is a strange fact that while the general death rate has been lowered all over the world, especially in the more civilized countries, as a result of improved hygienic conditions, better food, the theory and practice of sanitary science, and a more accurate knowledge and control of various infections, the mortality among infants has not declined in a corresponding ratio. It is certainly time to try and take more effective steps to check the heavy mortality at the very beginning of life. Much has already been done in the line of encouraging maternal nursing, improving the milk supply, a more careful and accurate study of the various methods of substitute feeding, a better knowledge on the part of physicians of infantile physiology and pathology, a consideration of the sociological factors involved in overcrowding, ignorance, and poverty, and a spread of the knowledge thus obtained to all classes in the community. Doubtless the efforts being made along these various lines will produce important results in the future. There is one aspect of the question, however, that does not seem to have received the attention and study it deserves. I refer to the management of foundlings, and neglected infants, who have not received proper home care. It is just this class of helpless infants that enormously swells the death rate. If a start could be made here in the proper direction, one of the most potent causes of infant mortality would be greatly ameliorated. The first step would be entirely away from institutional care, as the improved feeding methods and personal hygiene have not had the favorable effects expected while the infants are collected and retained in large numbers in one domicile. These old and futile efforts have been long and faithfully tried, and it is time that some other plans be instituted if the mortality among this class of infants is to be materially reduced. Let us first glance at the ill effects so constantly seen where these infants are managed in mass and then suggest another plan that aims to reduce these dangers to a minimum. All careful observers may note certain very constant phenomena among infants kept very long in an institution. One of the first conditions is a progressive loss of weight. This atrophy bears an inverse ratio to the age and is especially marked under six months. Older infants are less susceptible, but if kept long enough in an institution will nearly always show stationary and then losing weight. This often takes place while the infant is apparently digesting its food, which may be the best that can be artificially produced. Beginning atrophy, not depending upon any particular lesion, is always of serious import at this age. If it gets beyond a certain point no change of environment or food will save the patient. Accompanying this condition there is marked hydremia, dryness of the skin and wearing off of the hair from the occiput. A latent pneumonia, usually of the hypostatic variety, is apt to be the terminal condition in this type of case. It is very insidious, usually accompanied by little or no rise of temperature, and is nearly always recognized, perhaps for the first time, on autopsy. These infants are likewise very susceptible in infections of all varieties. Young protoplasm is very vulnerable to germs, especially when the general vitality is lowered. This explains the spread of acute pneumonias as well as catarrhal affections of the respiratory and gastro-intestinal tracts. The commoner communicable diseases also have a most favorable field. Diphtheria, measles, pertussis and less frequently scarlatina are, from the nature of these diseases, most liable to creep in. Diphtheria sometimes appears in older infants without apparent heteroinfection, doubtless from Klebs-Loeffler bacilli that may have long been latent in the throat. This is especially liable to happen in scrofulous infants with enlarged glands, nasal catarrh, and adenoids. Catarrhal and specific vaginitis is another scourge that is difficult to keep out of institutions and is more apt to attack the inmates who have had the longest residence. Otitis media is also occasionally to be noted as occurring almost in epidemic form. It is hardly necessary to enumerate any further list of dangers in this connection. The time has come for the medical profession to recognize the fact that an abundant experience all over the world shows that infants should not be collected and kept in asylums or institutions of any kind. The fault is not essentially with lapses in care or details of management, but with the system itself which fails because it is wrong.

A distinction may here be made between hospital care for the acutely sick infant and the ordinary

*Read before the Academy of Medicine (Section on Pediatrics), January 12, 1911.

asylum. Both have high death rates but the latter starts and deals with a well, or comparatively well, baby which gets sick during its sojourn in the institution. This makes a very radical difference. Even in hospital work extreme care should be exercised in view of the risks to which infants are subjected in collecting masses of them together. For infants and very young children the hospital should simply serve as a temporary place of refuge, where all hygienic, medical and surgical appliances should be of the latest and best types. After the acute illness has subsided, the infant should be immediately removed, as, otherwise there will be constant relapses and reinfections. The latter will occasionally occur even with the best nursing and under the finest hygienic surroundings in the hospital. The nurses must likewise be sufficient in number—one to five or six cases—and specially trained in this line of work. Even where all these conditions are fulfilled, the greatest care and watchfulness will be required and the infants must be discharged at just the right time when the acute symptoms have subsided and before a general cachexia or atrophy has had time to develop. In a word, in order to insure a good convalescence the infant must be kept in the hospital for only a short time; it must be carefully guarded from auto and heteroinfection while there, and, finally, sent out to recuperate under as favorable conditions as possible. The early discharge and "follow up" system was inaugurated by the writer at the Babies' Wards of the Post Graduate Hospital in 1890 and has been in successful operation ever since. A paid visitor, who is a trained nurse, inspects the home of the infant before its discharge, and, if conditions are unfavorable, the infant is sent elsewhere, usually to the country, for convalescence. If the care at home can apparently be carried out with some prospect of success the visiting nurse tries to see that right conditions shall prevail. In this way an effort is made to render any benefit permanent. There is no doubt that not a few infants discharged from an institution as improved or cured succumb later to weakness or lack of proper care during convalescence. The only remedy for this state of affairs is a continued oversight of the case. Hospital statistics, as such, are of little value unless they take into consideration the ultimate condition of the patient. This is true of all ages but especially so in infants. Many years ago Dr. Jacobi called attention to the susceptibility of infants to hospitalism (*N. Y. Medical Journal*, January, 1872) and his warning does not seem to have attracted the attention it deserved.

What shall be done with the many foundlings and neglected infants that drift from one institution to another in our large cities until finally they succumb either to hopeless home conditions or institutionalism? It is a most difficult problem involving helpless unmarried women, worthless or hopelessly poor and ignorant parents or social conditions that are hard to remedy. These infants cannot be allowed to die in the streets or in impossible home conditions. Hence the large asylums that are built for their shelter to do the best they can with their unpromising wards. The time has come to try another plan if what has preceded in reference to the older system is true. It is easier to criticise than to construct and if one has no better way to offer with reference to unfortunate results it were better to keep silence. The writer believes that a proper amplification and systematizing of boarding out with a careful "follow up" system offers this way. Relief must be aimed at along the lines of family life with individual supervision instead of the collective life with institutional methods. The unit of civilization is the family which offers the healthiest physical environment. The most susceptible member of the family to all external conditions is the infant. When transplanted from natural and normal surroundings the little ones suffer most. They need a certain amount of individual solicitude and care which indulges in handling, petting, and perhaps occasional foolishness—all embraced in the comprehensive term "mothering." They need the affection that even an ignorant but well meaning woman with motherly instincts can often give better than a nurse with the highest theoretical training even under a doctor in whom abstract science may be higher developed than common sense. The immediate surroundings may be poor, the ventilation not of the best, and the movements of the family not regulated by the highest social usages, but the infant will do better here in the long run than in the most immaculate ward. It is not proposed, however, to simply board out babies and then abandon them. They must be kept under constant oversight by some competent authority. There is nothing in common between a well organized system of boarding out and the old-fashioned baby farming which was justly abandoned owing to the many abuses that sprang up in connection with it. Boarding out with a proper and systematic "follow up" plan is a very different proposition; the failure of boarding out is due to a failure to utilize the latter plan.

It is proposed to abolish the large asylums and institutions for the care of these babies and substitute many small collecting stations. These stations will merely act as clearing houses to study the infant's physical condition for a day or so, find the substitute food that best agrees with it, and then board it out in the vicinity where it can be under constant oversight and regulation by a doctor and a nurse furnished by the station. This lessens the dangers of infection, avoids the evils of institutionalism, and at small expense puts the infants under the most natural conditions that are possible under the circumstances. Instead of paying for a large plant, the money will go toward the board of the infant and the salary of doctor and nurse. This will require much less outlay and at the same time give better results. The city stations can be in touch with similar stations in the country and an infant not doing well in town can be transferred to the country, where it will be under similar careful oversight. These babies must never be allowed to get away from constant and careful supervision if most of them are to be saved. Systematic, careful study of the field of operation is required if such a work is to succeed. Desultory, haphazard methods will not avail. The same care, routine, and system that are usually brought to bear in institutional work must be applied here. If thus operated it will have potent results, as it works principally through direct human instrumentality without depending too much upon a plant or a machine. A small house or part of a tenement house is all that is required for a station. It can house a doctor and a nurse with one or two attendants as required, or a few separate rooms for the very temporary stay of the foundling or homeless infant. As the baby is at once to be boarded out in the district, a few hours' stay will usually suf-

Fig. 1.—A group of atrophic infants now under treatment at Morristown, N. J.

fice. The station can also serve as a sort of child welfare center for the district. The nurse can be on call for sick infants of the surrounding tenements if the work is to be enlarged. The stations could be under the oversight of the Board of Health and directly managed by the present institutions if they could be induced to sell their large and expensive plants and work in this natural and hopeful way for their infants. Some of the great charitable foundations could here find a very promising field for quick but far reaching results. As far as inspections are concerned, the Board of Health is already working in this field as a permit is required from them before a child can be taken to board. An inspection of the woman and her home surroundings is made in each instance before the permit is granted. Dr. Baker tells me there are about 3,000 permits in force in the entire city at the present time. The children boarded out, however, are of all ages. From January 1 to November 1, 1910, 2,665 permits were issued and during the same period there was a total of 16,255 inspections. Permits are now issued for one year from date and are revoked automatically at the expiration of that time. This shows what a field has already been opened in this direction. What is needed is a correlation of all the forces at work to utilize this field to the best advantage. I believe the plan here outlined, if joined in by all institutions and agents at work for neglected infants, would immediately and permanently reduce not only sickness but death among them. It means, however, a more intensive working in many small fields, but all cooperating in a common system.

The only way to effectually test a theory is to try it out in practice and this the writer has done since 1902. A large number of neglected and abandoned infants were constantly being sent to the hospital because there seemed no other place for them. Such cases are not fit subjects for hospital care as all they need is proper food and environment. As the home conditions were usually hopeless they either had to be kept in the hospital indefinitely, or removed to some institution, or sent back to die at home if they were not already abandoned. To try and save this class of neglected infants the Speedwell Society was formed and the infants were boarded out at Morristown, N. J. In the operation of this work we have aimed to emphasize the following features: (1) Boarding out in a certain district of the country noted for its healthful conditions. (2) Constant attention to diet and hygiene on the part of doctor and nurse who are familiar with this class of cases and competent to deal with them. (3) The infants are kept as long as necessary, until feeding is regulated and digestion and assimilation are improved sufficiently to result in an increase in weight. The work is kept up during the whole year, and not limited to certain seasons. (4) The training up in a given neighborhood of a number of foster mothers, who, by constantly taking these infants into their homes,

Fig. 2.—Infant, 2 months; weight, 7 lbs. 12 oz.

Fig. 3.—The same as Fig. 2, returned in 4 months. Weight, 9 lbs. 14 oz.

Fig. 4.—Infant 11 months; weight, 12 lbs.

Fig. 5.—The same as Fig. 4, returned in 6½ months. Weight, 23½ lbs.

become fairly expert in handling them under conditions totally unlike those offered by the best institutions and far superior to them.

The results of this undertaking are as follows:

Since March 19, 1902, and up to January 1, 1911, 1,386 children have been received and 501 of these were under two years. As this paper deals with infants the latter only will be tabulated.

Received.

Under six months	241
Between 6 mos. and 1 year	120
Between 1 and 2 years	140

Died.

Under 6 months	91
Between 6 mos. and 1 year	22
Between 1 and 2 years	6

There was only one death over two years of age among 885 cases. The causes of death were as follows:

Bronchopneumonia	5
Cholera infantum	1
Chronic gastroenterocolitis with malnutrition	28
Chronic enterocolitis with malnutrition	23
Croupous pneumonia	2

Fig. 6.—Infant 13 months; weight, 9½ lbs.

Fig. 7.—The same as Fig. 6, returned in 9 months. Weight, 23 lbs.

Rachitis with malnutrition	3
Diphtheria	1
Marasmus	49
Meningitis (tuberculous)	2
Scarlet fever	1
Prematurity	3
Tuberculosis	1
Pyloric stenosis	1
	120

It may be considered that the death rate is large by those unaccustomed to deal with this class of cases. It is safe to say, however, that practically all of the younger infants would have died if kept in an institution. They were poorly nourished from bad hygienic surroundings, with various degrees of digestive disturbance from faulty feeding by bottle and stationary or losing weight. Aside from the fatalities, those not dying usually made a good and permanent recovery. A large proportion were restored to fair and even vigorous vitality, although kept on the bottle. While wasting in infants is largely due to faulty diet in its inception and continuance, yet when the atrophy has proceeded to a certain degree, a change to a proper diet is not usually sufficient to check the downward trend. These cases require, in addition, an altered environment that will furnish plenty of fresh air, good general hygiene, and individual care. This is the reason that they do not do well in institutions even when carefully and scientifically fed. They cannot seem to assimilate the best of food without an abundance of good air to assist in its oxidation; oxygen is as necessary for them as protein or fat. It is only individual housing and care with constant oversight that can furnish these requirements. The infants are kept until they are essentially improved, the average stay being four months. Many are kept longer, one feeble infant being retained for two years, but left a strong, vigorous child.

It is always preferable in rescue work to permanently help a few cases rather than aiming only temporarily to aid many.

During the eight years of continuous work, 70 families have been given babies to board. There is naturally a difference in the spirit and capabilities of the various foster mothers. Some do better than others and the doctor and nurse have them graded in their own minds as to their success and efficiency. Some of these foster mothers have been very successful in nursing feeble infants back to health and take the greatest interest in the work. Others tire of the work or are dropped because of inefficiency. The various remaining reasons for stopping the work are noted as removal from town, going out to work by the day, other births in the family and death of foster mother. The important and interesting thing is that it is not difficult to get another family when, for any reason, an old one is given up. From fifteen to twenty families are usually employed and some of the most capable foster mothers are given two infants. An effort is made to encourage them by praise as the pecuniary reward—$12 per month—is not large. That their

Fig. 8.—Visiting nurse making rounds.

work is generally efficient is shown by the fact that only thirty-three infants have been returned unimproved since the starting of the work. The deaths among the ill-nourished, marasmus babies have already been reported. The tact and good judgment of the supervising matron are constantly called into play in retaining old homes that are satisfactory and in selecting new ones. It is necessary to thoroughly know the locality and the people to succeed in this kind of work. For this reason it is better to operate in a comparatively restricted area, whether in city or country . Systematic, careful study of the field of operation is always necessary.

If the plan thus elaborated could be carried out generally in the place of institutional work for feeble, neglected babies, a large majority of them would be saved. No capital is required to be tied up in a large building or plant. The plan has proved to be economically sound as well as practically efficient.

51 West Fifty-first Street.

SYPHILIS AND THE NERVOUS SYSTEM, WITH REMARKS ON THE WASSERMANN TEST AND "SALVARSAN."*

By WILLIAM M. LESZYNSKY, M.D.,

NEW YORK

NEUROLOGIST TO THE HARLEM AND LEBANON HOSPITALS; CONSULTING NEUROLOGIST TO CHRIST HOSPITAL, JERSEY CITY, ETC

In view of recent developments in the diagnosis and treatment of syphilis, the time is opportune for recalling some of the established facts relating to syphilogenous diseases of the nervous system.

It is well known that syphilis is one of the most frequent infectious causes of organic nervous disease. Hence, in every patient who appears with symptoms of disease of the nervous system, we must ascertain, if possible, whether he has ever contracted syphilis. This is comparatively difficult with women patients. In every doubtful case we are forced to depend upon the existence or non-existence of somatic signs of the disease, the collateral symptomatology, and the character and course of the nervous manifestations. When it is discovered that syphilis has been acquired at some more or less remote period, it does not necessarily imply that every morbid condition of the nervous system which develops in the subsequent course of life should at once be attributed to this early infection. Although such an individual is more apt to develop nervous syphilis, he is in no sense exempt from other (non-syphilitic) nervous disorders.

On the other hand, there are certain rather characteristic symptoms occurring in connection with lesions of the nervous system, which are unmistakably traceable in almost every instance to a previous or existing syphilitic process.

When confronted with a disease of the nervous system in which the etiology seems obscure, on account of the absence of a history of previous luetic infection, the physician has frequently expressed his conviction to the patient that an antecedent syphilis would simplify the treatment, and thereby insure a favorable result. This erroneous idea is still unfortunately more or less prevalent, not only among laymen, but likewise among physicians. Such an optimistic view is unjustifiable, and frequently leads to disappointment. It is usually based upon a mistaken conception of the pathology of the disease, or a credulous adherence to ancient and traditional doctrines.

Some clinicians assume a heterodox attitude in stating that recently acquired syphilis, whether thoroughly treated or not, uniformly passes into the tertiary stages of the disease. No matter how much polemic argument is indulged in on this point we are forced to acknowledge from practical clinical experience that patients in whom a thorough and systematic anti-luetic treatment was carried out during the early stage following the primary infection, are not insured thereby against subsequent syphilitic disease of the nervous system. In these patients, however, it would seem that the symptoms appear in milder form, as compared with those who had never received suitable early treatment. That the degenerative types affecting the cerebrospinal system often appear despite vigorous early treatment is too well known to be denied. But this may often be attributed in part to depressing influences, such as waste of energy and vitality from various forms of dissipation, etc., or to some special individual susceptibility of the central nervous system. It will thus be seen that we do not, as yet, possess any sure remedy which will absolutely protect the nervous system against its ravages when syphilis has once been acquired.

In this connection, it is important to recall that cases of organic disease of the nervous system frequently arise in which syphilis is positively denied, and no cutaneous or other signs discovered, but, from the suspicious or obscure character of the symptoms it is important to determine, if possible, whether the disease has developed on a syphilitic basis.

Hitherto, the etiological diagnosis has been undertaken by the so-called therapeutic test, the diagnosis ex-juvantibus (*i. e.*, if the manifestations subside under the use of mercury and iodide of potash syphilis must be present). Although this plan has been of great service in many instances, as a rule it is unreliable, for it has long been a well-known clinical fact that other pathological processes react favorably, if not so rapidly, to the use of anti-syphilitic remedies. Several patients have been under my care with unmistakable signs of intracanial tumor. After the use of mercury and iodine the symptoms subsided for several months. Ultimately, at the autopsy, sarcoma was found without any evidence of syphilis. This is not an uncommon experience in neurological practice.

To-day we are more scientific, but are too rapidly accustoming ourselves to depend too much on modern sero-diagnostic methods in place of careful clinical observation, in the solution of this old problem. The Wassermann hemolysis test is just now very popular, being enthusiastically adopted as a standard. A positive Wassermann reaction is in the majority of cases assumed to be indicative or presumptive of a pre-existing or active syphilis, but we must be cautious in depending upon it exclusively, as it is by no means an infallible test and should *be received only as confirmatory evidence.* A positive Wassermann reaction having been found in a case of brain tumor, it was assumed that the growth was syphilitic. The usual specific medication produced no improvement. At the autopsy, a gumma was found in the liver, but the brain tumor was a gliosarcoma (Spiller). On the other hand, when clinical signs of syphilis of the nervous sys-

*Read before the Williamsburg Medical Society, January 9, 1911, and before the Passaic County (N. J.) Medical Society, February 14, 1911.

tem are present, the report of a negative Wassermann reaction should not be interpreted as conclusive proof of the absence of syphilis. We must also bear in mind that the Wassermann test remains negative during and soon after the use of mercury. A negative Wassermann reaction no more excludes syphilis than the absence of tubercle bacilli in the sputum excludes pulmonary tuberculosis. The elaborate and complicated technic necessary is not at all adapted to general usage. Furthermore, there are comparatively few laboratory workers whose report can be safely accepted as absolutely reliable.

The presence of an excess of lymphocytes in the cerebrospinal fluid and the Noguchi globulin reaction are extremely valuable. Their demonstration in conjunction with a positive Wassermann reaction in the blood and cerebrospinal fluid is, according to the recent observations of Nonne and others, conclusive evidence of the presence of syphilis. Moreover, they are indicative of some irritative or inflammatory process. When found in the degenerative types of disease of the central nervous system, we are justified in assuming that the pathological condition is not a purely degenerative one. Hence, a course of antisyphilitic treatment is in order, especially when active clinical manifestations are present.

Lumbar puncture, however, is inapplicable in ambulatory patients. It is often inexpedient, and should not be practised without judicious discrimination. Innumerable physicians think it is a serious or dangerous procedure. And so it is, in the hands of inexperienced or careless men. Among the hundreds of punctures that I have made I have never witnessed any bad results. For diagnostic purposes, it is unnecessary to withdraw more than five cubic centimeters of fluid, and the patient should invariably remain in bed in the horizontal position for twenty-four to thirty-six hours.

In a recent comprehensive and conservative article (*Journal A. M. A.*, December 3, 1910) Kaplan concludes, after two years' experience with the Wassermann reaction, comprising 3,200 tests, that, as a test for diagnostic and therapeutic purposes, it has been greatly overrated, and that a positive Wassermann reaction does not always spell syphilis. In tabetics, during the active stage of the disease, it was present in 88 per cent; in the quiescent period in 40 per cent. In 300 unclassified cases of tabes the Wassermann reaction was positive in only 66 per cent.

Undoubtedly a very large percentage of tabetics have had syphilis. Whether the absence of the Wassermann reaction in 34 per cent. of tabetics can be utilized in substantiation of the view that all tabetics are not syphilitic remains an open question.

It is a remarkable fact, familiar to all neurologists, that in many patients whom we see with unmistakable signs of nervous syphilis, the primary lesion has not been followed by any recognized secondary symptoms. Careful interrogation results in the information that there was an indurated chancre on the prepuce, with or without enlargement of the inguinal glands, and that is all. It is probable that a roseola was present, but was overlooked. The absence of early treatment in these mild cases of acquired syphilis may account for the frequency of such conditions.

The syphilitic poison, when it invades the nervous system, affects it in several characteristic ways. 1. It may attack the intracranial or spinal arteries, producing an endarteritis, which gradually leads to thrombosis and occlusion of vessels, thus cutting off the blood supply to the corresponding area. 2. It may give rise to a gummatous growth, or to a local or diffuse gummatous exudate, involving the meninges and infiltrating the adjacent brain structures. This specific inflammatory process may gradually press upon, or ultimately destroy, by new connective-tissue formation, conducting fibres or nerve-cells. 3. The nutrition of specially susceptible cell-structures and fibre tracts may be slowly interfered with, the cell substance and its processes undergoing gradual degeneration. The first two forms are known as "inflammatory" or "exudative," and are usually more or less acute in their onset. They are not always late manifestations, for they often occur within the first two or three years, and may arise within a few months after infection. The last has been characterized as "degenerative" or "parasyphilitic" and is essentially chronic. The forms of brain syphilis most dangerous to life are obliterative cerebral endarteritis, and basal meningitis, and meningo-encephalitis extending to the posterior fossa.

While it is virtually admitted that syphilis is an incurable constitutional disease, paradoxic as it may seem, it is the most amenable to treatment under certain conditions. The fact should be well understood by all, that while many of the effects of the disease are thus amenable, there is no method at the present time by which we can eradicate the virus or its toxins from the system and be enabled to say positively that the patient will remain free from further attacks. The spirochetæ and their toxins may remain latent for years, unexpectedly manifesting their potency through some unknown exciting cause.

Exudative inflammation, gummatous growths, gummatous meningitis, and meningo-encephalitis, pachymeningitis, obliterative endarteritis, and periarteritis are *the* conditions amenable to antisyphilitic treatment and constituting one of our most brilliant therapeutic achievements.

A clear comprehension and appreciation of the following important facts should serve to discourage and warn against useless, if not dangerous, medication:

1. Syphilitic inflammation produces more or less exudation, which terminates in the formation of connective tissue. Should this fibrous tissue entangle nerve cells or fibres in its meshes they may be permanently destroyed. The symptoms that result from this interference with innervation or conductivity, when they have persisted for months or years in spite of active measures, are those that prove unamenable to further antisyphilitic or any other form of treatment.

2. When a cerebral artery becomes the seat of thrombosis, and this is most frequently the middle cerebral or its branches, whether such obstruction be superinduced by syphilitic endarteritis, atheroma, or embolism, the immediate results are the same. The interference with the nutrition of the corresponding cerebral area is shown by either partial or complete loss of physiologic function. The degree of the disturbance depends on the size of the vessel involved, the extent of structure which it supplies, and on its partial or complete occlusion. When the calibre of a small cortical vessel is obstructed or obliterated, there may be some restitution of function through the early establishment of a collateral circulation. This does not occur, however, when a large artery becomes closed. The result of the cutting off of the blood supply is necrotic softening. This dead

brain tissue cannot be restored by antisyphilitic treatment. In many of the patients in whom occur transient monoplegia, or hemiplegia, or aphasia, or attacks of petit mal, or other loss of consciousness, these symptoms are occasioned by beginning thrombosis of cerebral blood vessels.

3. Cerebral hemorrhage of the familiar form, destroying the motor fibres of the internal capsule, may be the result of the rupture of a syphilitic artery. It is the hemorrhage that has done this damage mechanically, and the resulting paralysis can no more be correctly termed "syphilitic hemiplegia" than the hemiplegia resulting from necrotic softening. In both instances, certainly, syphilis is recognized as the remote cause, but the destruction of this portion of the motor tract is irremediable. Hence, it is not only useless, but harmful, to persist in giving such patients either mercury or iodine for an indefinite period. It will thus be seen that much of the syphilis of the central nervous system is indirectly the result of syphilitic arterial disease.

It has been said that there is no form of syphilitic nervous disease which should exclude "specific" treatment. From such a misleading statement it might be inferred that mercury and iodine are also beneficial in all cases of the so-called parasyphilitic affections, among which have been included a large percentage of cases of tabes, paretic dementia and progressive ophthalmoplegia. These diseases are degenerative in character. When uncomplicated by a specific inflammatory process they are not benefited by such treatment. One difficulty in this matter lies in the possibility of mistaking exudative cerebrospinal syphilis for true tabes.

I mention tabes, because it is the most common and representative type in this category. Patients with tabes, for instance, who have had syphilis, but have never received antiluetic treatment since their tabetic symptoms developed, should be given a course of active mercurial medication. If this has already been carried out without relief, it is useless, nay, harmful, to repeat the procedure. Not only have I never seen such patients improve by this means, but I have repeatedly noted an increase in the degree of many of the symptoms, presumably as a result of interference with the general nutrition.

The over-zealous and injudicious use of mercury and iodine has often proved disastrous in patients with diseases of the nervous system. In several instances coming under my observation it has required many months to counteract the injurious effect of such treatment which proved more serious than the original nervous affection itself.

Let me tell you, gentlemen, not to forget that the treatment of patients with syphilitic affections of the nervous system is not limited to the administration of specific drugs. Time will not permit of explanatory details, or of the narration of illustrative cases. As individuals differ in personality, constitution, idiosyncrasy, etc., so does the activity of the syphilitic poison and the reaction to treatment vary in different persons. From what has been said, we need not assume an attitude of hopelessness regarding parasyphilitic cases, for much else can be done to alleviate their suffering, improve their mental and physical condition, and retard the progress of the disease.

After laborious scientific investigation, Ehrlich discovered the arsenical compound which he claimed was capable of destroying the spirochetes of syphilis, and gave it the name of "606." (It has since been termed "arsenobenzol" and is now known as "salvarsan.") He then wisely placed a large quantity in the hands of well-known physicians in Germany (and some with physicians in this country) for clinical experimentation in the hospitals, before permitting its distribution to the general profession.

It has now been used in about fifteen thousand cases, and, of course, the most extensive and elaborate reports have come from Germany. It is extremely interesting and suggestive to note that, at first, enthusiasm as to the wonderful "cure" permeated all of the articles on the subject published in the German medical journals. Gradually, but inevitably, as experience increased, and the results of the treatment were carefully recorded and critically analyzed, this was replaced by conservative and sober judgment.

Briefly summarized, recent German and American literature shows that all admit that we now possess a new and valuable remedy against some of the manifestations of syphilis. That it is of special use in cases that prove intolerant, or do not react favorably to mercury, especially in the cutaneous and gummatous phases of the disease. That it will often produce rapid and remarkably brilliant results, but that it is not always superior to mercury. That it is of very little use in parasyphilitic affections, and is positively injurious in advanced cases of chronic organic nervous disease. And that the heralding of the remedy by unauthorized persons as a "positive cure" was premature.

For many years we have succeeded in practically curing certain syphilitic affections of the nervous system. We have all learned that the most effective specific drugs have been first and foremost mercury, and iodine as an adjuvant. When improperly used, they have often been inefficient, and when abused have been obviously injurious. But, when properly administered, they have proven our most valuable therapeutic resource.

It would seem that, as an immediate outcome of the present agitation and enthusiasm regarding the alleged panacea salvarsan, our venerable, respected, and faithful friend, mercury, is to be deposed, laid on the table, and abandoned as already obsolete and useless. In other words, to be replaced at once by salvarsan, a rival whose potentiality is not yet thoroughly understood, and which will, in all probability, require ten or fifteen years to fully establish its superiority or supremacy. *Festina lente.*

If salvarsan succeeds in permanently destroying all spirochetes and their toxins in the early stage of syphilis, the disease will be robbed of its terrors as to the possible later advent of cerebrospinal syphilis and the ultimate progressive degeneration in the central nervous system.

Thus far it has been shown that the so-called parasyphilitic processes are not only not benefited by the use of salvarsan, but that in some cases deleterious results have supervened. In those forms of syphilis of the nervous system that have usually proved amenable to mercury, salvarsan has been reported as acting more rapidly and efficiently, but in many instances recurrence has taken place, necessitating a repetition of the treatment. Hence, it is to be used only in selected cases.

In a recent article (*Deutsche med. Woch.*, December 8, 1910), Oppenheim reports the very instructive case of a man who had newly acquired syphilis in April. On June 30 he was injected with salvarsan by Wechselmann. In the middle of August he developed a pronounced form of brain

syphilis (gummatous basal meningitis). Progressive improvement followed the use of potassium iodide. As a result of his clinical observation of a large number of cases, he concludes that in cerebral, spinal, and cerebrospinal syphilis it is no better than mercury and iodides. Its beneficial effect is shown mostly in gummatous processes, while it has very little influence over endarteritis and syphilitic spinal paralysis. It must not be depended upon alone in this class of cases. In some tabetics the only benefit exhibited was some improvement in the subjective symptoms, which may have been due to suggestion. In others it proved injurious. The decision regarding its administration to a tabetic he considers a great responsibility.

In view of the facts that the introduction into the system of salvarsan is known to be attended at times with sufficient danger to require a preliminary investigation as to the condition of the heart, kidneys, and visual apparatus as a routine measure, and that, even in suitable cases, under the most careful and perfect technique, its administration has been followed by disastrous consequences, due care and conservatism should be exercised in its utilization.

I certainly have neither justification nor desire to belittle its value in syphilotherapy, nor to question its surprising efficacy in special forms of cutaneous and inflammatory syphilis. I believe it has come to stay, and that it is too good a remedy to be abused.

Now that the drug is on unrestricted sale in the open market, imminent danger is to be apprehended from its indiscriminate use. Therefore no special inspiration is necessary in order to predict some of the unexpected and deplorable happenings in the near future. History always insists on repeating itself, with an unfortunate predilection for events of an unpleasant or distressing nature. The laity as well as the medical profession have been led to believe that a "sure cure" for syphilis has been discovered, and those who wantonly neglect the precaution of avoiding suspected sources of venereal infection are indulging in a false sense of security. Rash promises of cure on the part of the physician must inevitably lead to many disappointments.

Within recent years remarkable progress has been made in the discovery of the *Spirochæta pallida* and the brilliant achievement of Ehrlich in the introduction of arsenobenzol. Let us all look forward with the hope that in the near future further research will lead to the extermination of syphilis, which is recognized as one of the greatest scourges of civilization. At the present time the prevention of syphilis is practically an unsolved problem.

145 West Seventy-seventh Street.

PRIMARY STERILITY IN WOMEN.*

A STUDY BASED UPON 120 CASES.

By A. J. RONGY, M.D.,

NEW YORK,

ADJUNCT GYNECOLOGIST, LEBANON HOSPITAL, ATTENDING SURGEON JEWISH MATERNITY HOSPITAL.

Introduction.—The observations and conclusions arrived at in the following paper are based on a thorough analysis of 120 patients who presented themselves for treatment for primary sterility during the past ten years. Only those cases are included in which both husband and wife were examined. All the other cases of sterility in which the examination of the husband was not feasible are excluded, although a great number belonging to this class were treated. The family and personal history of each patient and of her husband were carefully gone into. The limitations of propriety and modesty as a rule interfere with the bringing out of very important etiological factors in a great number of patients. Every patient was closely questioned with the object of eliciting some cause or causes most prominent in the production of absolute sterility.

Those who have followed the subject carefully are aware of the change of opinion that has taken place in the last two decades regarding the relative responsibility of husband and wife for the sterile condition. Formerly, the fact that the husband was capable of performing the act of cohabitation was sufficient proof that he was able to reproduce and the woman was held responsible in all other instances. Now we know the folly of this doctrine. Even to the present day some religions base their divorce laws upon the above unscientific principle. The treatment of sterility has also undergone great transformation since Marion Sims formulated the mechanical theory as the most prominent cause of absolute sterility. The average practitioner in the majority of instances suggests some form of mechanical operation on the cervix, usually dilatation and curettage. In the light of modern investigation one can perceive how incorrect this procedure is in a great number of cases. It is with these facts constantly in mind that the writer has undertaken to gather material for an analytical and statistical study of the subject, of which there is little to be found in the American literature.

The subject of sterility is important from a medical and sociological standpoint. It is important to the community at large as well as to the parties concerned in the marriage contract. Sterility is rapidly increasing in the United States, especially in the native-born white women. In 1900 it was 20 per cent. among natives, while among foreigners in the United States it was 13 per cent. It is greater in the United States than in any other country except France (Engleman). Simpson, out of 1,252 marriages, found 1 in 8.5 unfruitful; Ansel, in the British peerage, found 1 in 6 1-9; Engleman, among college graduates, 1 in 3 1-3; Kisch, in 626 marriages, found 70 sterile. Spencer Wells and Marion Sims give 1:8 as the relative frequency. In my own records from private practice and from my clinics at the Lebanon and Post Graduate hospitals in a series of 1,600 patients I found 202 sterile, or about 1:8. Sterility is dominant in all classes, but is more prevalent among residents of metropolitan cities, for reasons which are obvious. Formerly the ignorant and the poor classes suffered less than the richer and well-to-do classes. Now civilization has brought about a mode of life in the complex population of our cities in which the average youth finds a ready outlet for his sexual desires, bringing back to his future home and wife the affliction which such acts frequently entail. It is my plan to follow in this paper the routine which I have adopted in my history sheet, from the inquiry of the family history to investigation of the present state of the patient, in this manner bringing out the most important groups of symptoms.

Family History.—In eight patients there was sterility in either a sister or a brother. Three of these patients presented a few symptoms that pointed to some congenital defect of the genital organs, that is, late oncome and scanty menstruation, small

*Read at the October meeting of the Clinical Society of the Jewish Maternity Hospital.

vagina and small uterus. The husbands of these patients had active and living spermatozoa. It seems that the family history has no bearing on sterility. The history of infancy and childhood may have some bearing on the etiology of sterility, but with the average patient one is left in the dark. Most of them had the usual diseases of infancy and childhood. Whether the infectious and contagious diseases play any rôle in the etiology of sterility is yet uncertain, but that they may do so is very apparent from the studies of Winckel, who found an acute inflammatory process in 25 per cent. of cases that died from contagious and infectious diseases. It is rather very probable that the genital tract may be permanently damaged in a number of cases.

I have laid particular stress on the question of vaginal discharges during infancy and childhood, but as a rule did not get satisfactory information. Yet, according to the studies of Holt and Koplik, a large percentage of the vaginal discharges during infancy is of gonorrheal origin. Would it not be reasonable to assume that in a large number of the protracted cases, particularly in its chronic form, the infection ascended to the tubes, causing an insidious inflammation of the lining membrane of the tubes and permanently damaging them either by occlusion or causing small adhesions with constriction of the lumen? In this series I know of two patients who had had specific vaginitis, one at the age of 7, the other at the age of 9; both had been properly treated and apparently cured.

Puberty.—The onset of menstruation in this series is of no significance, as the majority of the patients came from various parts of Europe. Only 28 were native Americans. The average age of onset among the foreign born was about 14, while among the native Americans it was 13. In two patients menstruation first appeared at the age of 17, in one at the age of 19, and disappeared at 22. It was very painful and irregular while it lasted. Nearly 85 per cent. suffered from dysmenorrhea, particularly during the first two days, a fact which goes to prove that the pain was not merely due to mechanical obstruction, but that some derangement of the genital tract, most probably of inflammatory origin, was present, which caused the pain, for were it only of mechanical origin the pain would have ceased as soon as the full flow was established.

The menstrual history of the patient is one of the most important gynecological symptoms. Normal menstruation usually means normal local and general conditions. Any change in the menstrual history of the patient always signifies some acquired pathological condition, usually of the reproductive organs, but possibly of a general nature. I believe this to be the most important guiding symptom in our field of work. Patients who menstruated regularly without pain prior to their marriage, in whom menstruation became irregular and painful soon after, surely have an inflammatory process of the lining of the uterus or the tubes, although on physical examination very little evidence was discovered with the possible exception of a slight posterior parametritis, and at times even this was absent. Particularly was it true of cases in which the infection was not of an acute nature. The pathological changes developed slowly and gradually, the patient herself hardly noticing them. Twenty-one patients had no menstrual disturbance; the flow was regular as to the time of its occurrence, and as to the amount of blood lost, and was not painful.

Occupation.—Most of the patients attended to their housework. Two were teaching school, 6 had millinery shops, 8 divided their time between housework and small stores they owned, 2 were stenographers, 1 a dentist. Prior to their marriage the majority of the patients had been engaged in sedentary occupations in close quarters and for prolonged hours, were rather anemic, and not in a robust state of health. I believe that the sedentary occupations are great causative factors in the production of the various forms of displacements of the cervix and uterus. They prevent the proper development of the genital organs and surely interfere with the proper performance of their functions. It is a clinical fact that girls who had been free from pain during menstruation prior to beginning work usually begin to suffer from dysmenorrhea after having been engaged in a sedentary occupation for a year or more. At this period a great number began to suffer from leucorrheal discharges signifying some irritation along the vaginal and uterine canals, probably at a point on the posterior wall of the uterus near the internal os. Patients who led an outdoor life, or who were engaged in occupations that required a certain amount of physical exercises, usually did not suffer from painful menstruation and their periods were regular.

Age at the Time of Marriage.—Fifteen were under 20, fifty-three between 20 and 25, thirty-eight between 25 and 30, seven between 30 and 35, four between 35 and 40, and one over 40. I believe that this is the proper ratio of the ages, and therefore has no special significance. Age has no bearing on sterility in women, except when it reaches beyond a certain point. Once a woman menstruates normally conception may take place. For whatever the theory of the relation of ovulation and menstruation may be, whether the older theories of Bischoff and Pflüger or the later theories of Sigmund, Gusserow, Lowenhard, and Strassman are accepted, all agree that as long as a woman mestruates ovulation takes place, and therefore impregnation may take place in the absence of pathological processes of the genitalia. Personally I believe that menstruation is not directly dependent upon ovulation any more than ovulation is dependent on menstruation; that menstruation, ovulation, and lactation to a degree are physiological functions performed by distinct organs peculiar to the female sex, that all are dependent on each other in the sense that if one of these physiological processes is made impossible, either by lack of development or surgical removal, eventually the other functions will also disappear. There are many clinical evidences to prove this, the discussion of which will be taken up at some future date. However, the prognosis is better in young women, for resolution of diseased processes and restoration to the normal will take place more speedily in younger people. In one of my patients the time that elapsed between the operative interference and the clearing up of diseased processes of the tubes was seven years. She is at present in her fourth month of pregnancy, is 29 years old, and married over 8 years. The same condition consuming the same length of time to resolve, in a woman over thirty years old, most probably would have prevented impregnation.

Consanguinity.—Some authors state that the marriages of near relations are more likely to be barren. In my experience such is not the case. In people whose religion permits the marriage of very near relatives sterility does not seem to be more prevalent. The Jewish law permits the marriage of an uncle and niece, the marriage of first and second

cousins is of very common occurrence, and the proportion of sterility as a result of such marriages is not greater. Eight of my patients were married to very near relatives, but the sterile condition in each insance was due to other existing conditions.

Masturbation and Sexual Incompatibility.—Nine patients practised masturbation daily from about the age of sixteen until they married. Two continued the practice after marriage, stopping during the menstrual flow only. This continued practice resulted in complete sexual anesthesia in seven patients. The vaginal vault presented a hard shriveled appearance. One could hardly differentiate the line of demarcation of skin and mucous membrane. The vaginal mucous membrane was absolutely dry. These patients are not amenable to treatment and the prognosis is very poor, notwithstanding any effort at a cure. They are usually very anemic, in poor health, highly nervous, and very unsatisfactory subjects for treatment. The explanation of their sterile condition lies in the fact that the constant irritation of the parts leads to hyperemia of the ovaries and this chronic congestion produces a chronic productive inflammation resulting in what is clinically know as cirrhosis of the ovaries. Usually when these patients present themselves for treatment the changes in the ovaries are fully established. Their menstrual flow becomes very scanty and of short duration. This is almost a pathognomonic symptom of prolonged masturbation.

Sexual incompatibility or want of sexual affinity is a very important factor in sterility. In almost every instance the woman is sexually stronger. The act of copulation is not satisfying to both alike, an element which is very essential and must not be overlooked. The husband usually being sexually weaker must be educated to prolong the act of coition. One of the best means to do so is to instruct the husband to concentrate his mind on some important matter during the sexual act, or to begin a mental count of numbers. I find that the act is prolonged if these instructions are followed out. They also must be advised to control their passions so that they do not immediately become overexcited.

Vaginismus.—In the presence of vaginismus sterility is the rule. Three patients in this series suffered from a very severe form of this condition. The act of copulation was not properly performed. One patient had the hymen intact eleven months after marriage. This condition must be speedily relieved, and while in simple cases forcible dilatation of the vagina under anasthesia will cure it, in the severe forms the method followed by Pozzi produces the best results. Vaginismus is usually associated with dysmenorrhea of mechanical origin, and it must be relieved by one of the mechanical operations upon the cervix. Usually simple dilatation with the introduction of a stem pessary into the cervix, to be kept there from two to six weeks, will cure the pain accompanying the flow.

Dysparcunia.—This is usually a very prominent symptom in sterility. Thirty-two of the patients suffered from it. In some patients the pain is so intense that they refuse to have sexual intercourse. Few of the patients dreaded the very thought of the sexual act. The pain is of a sharp lancinating character, so severe at times that two of my patients almost went into shock during an attempt at coitus. The etiology of this condition is so manifold that I shall not attempt to enter into a discussion of it just now, but shall point it out more fully when treatment shall be taken up. It is needless to state that no treatment of sterility is complete without the cure of this condition.

The Male Aspect.—It is admitted by competent investigators that in 50 per cent. of all cases of absolute sterility primarily the husband is at fault, and this ratio is constantly on the increase, particularly in larger cities. Conception cannot take place unless the seminal fluid contains well developed living and active spermatozoa. It is the duty of the physician to examine a great number of seminal specimens in order thoroughly to familiarize himself with the microscopical appearance of spermatozoa and to be able to satisfactorily pronounce a given specimen as normal, for it is not sufficient that spermatozoa are found. It should, as far as possible, be established that some of the spermatozoa will reach their point of destination fully active, and in condition to impregnate the ovum. The individual spermatozoon has to travel a distance of at least 24 cm. and the time consumed in doing so, no matter how moderately rapidly it will progress, will be one hour and a half. Many obstacles will delay its journey, and hence its travel will be prolonged. Many specimens of semen that I have examined, showing living spermatozoa not of the very active variety, when examined two hours later, after having been kept in a warm, normal salt solution, showed no trace of a living spermatozoon. Would it not be logical to conclude that such spermatozoa will die during their travels before they will meet the ovum to impregnate it? Such conditions are very frequently met. They usually indicate a debilitated state of the individual. In addition to general treatment, the patient must be instructed to abstain from any sexual excitement for some time.

Generally speaking a woman should never be treated for absolute sterility unless the seminal fluid of the husband has been thoroughly examined and spermatozoa found. At times it is rather difficult to obtain a specimen, but if the case is properly presented to the parties concerned, usually the specimen will be forthcoming. The practice commonly pursued by physicians, and particularly in our general hospitals, of operating on women for the cure of sterility, without first examining the husband, cannot be too strongly condemned. It should never take place in the well regulated gynecological service of a public hospital. Not only is one not sure that the operation will result in a cure, but a great onus is put on the woman if she still remains sterile. The husband takes it for granted that as long as a woman requires an operation the fault lies absolutely with her, otherwise she would not have been operated on by surgeons of good standing and established reputation. Such procedure has its demoralizing effect both on husband and wife and should, as far as possible, be avoided.

The importance of azoospermia as a cause of conjugal sterility has been shown first by Kehrer of Heidelberg, who found azoospermia in not less than 30 per cent. of the married persons who consulted him on account of sterility as the sole cause of the latter. This figure has been confirmed by Busch, Fürbringer, Gosselin, Lier-Ascher, and many others. Fürbringer found in 600 husbands of sterile women as much as 83.3 per cent. of azoospermia or serious oligospermia (A. Neisser). Of the 120 patients in this series, 38 suffered from aspermia, 16 from relative oligospermia. In cases of relative oligospermia the diagnosis should never be based upon the examination of one specimen only. Sexual excesses will produce a temporary oligospermia. Overwork

and great mental disturbance will interfere with the production of well developed spermatozoa. The use of narcotics, particularly alcohol, brings about a great diminution in the number of spermatozoa in a large number of cases.

It has been my rule in cases of oligospermia, or even in aspermia, which evidently is not of organic origin, to stop all sexual excitement for at least six weeks, to regulate the general mode of life as far as possible, and if no improvement is found as to quantity and quality of the spermatozoa the prognosis is very unfavorable.

The causes of azoospermia and oligospermia are many. They are both of general and local origin. The most important factor in azoospermia is gonorrhea and its complications. This etiology has been so well established that it is no longer disputed. Our appreciation of the awful prevalence of the disease originated with the observations of Noeggerath in 1878, but the full significance of the lesions and their extent was made possible by the discovery of the essential cause, the gonococcus of Neisser, in 1879. Noeggerath's statistics at that time provoked no little criticism. He stated that eighty per cent. of married men have had gonorrhea; that ninety per cent. of these have never been thoroughly cured, and that of five married women three have gonorrhea. At present one is ready to admit that Noeggerath was right when he said that the gonococcus can exist in the tissues throughout the lifetime of the individual and, at any time, under favorable influences the infection may light up into what appears to be a new and acute process and may transmit a virulent infection without itself becoming manifest (Palmer Findley).

I am absolutely convinced that chronic gonorrhea is incurable. Once the process extends into the posterior urethra it does not stop there; in the majority of patients the prostate and seminal vesicles are involved and complete restoration to the normal seldom, if ever, takes place, although all the clinical signs may have disappeared. That in the majority of cases the infection extends to the prostate and seminal vesicles is proved by the investigations of Colombini, who found this true in 40 per cent., Montagon, in 70 per cent.; Pezzoli, in 80 per cent.; Casper, in 85 per cent.; Woelsch, in 81 per cent. Lier and Ascher found that in 80 cases of azoospermia 75 were due to gonorrhea. We must not only take into consideration the effect that gonorrhea has in the production of sterility in the male, but the secondary complications which take place as a result of this infection in the woman. The husband may have had gonorrhea and yet not be sterile, still he will infect his wife, and if the infection extends to the body of the uterus and adnexa she becomes absolutely sterile. This is what actually takes place in a great number of cases. The infection in the woman does not depend upon the amount of the discharge, nor does its constancy indicate the degree of virulence. The presence of the gonococcus in the absence of a discharge has been demonstrated. The absence of gonococci in unquestionable old gonorrheal infections is very frequently met with. A woman may have gonorrheal infection with very few and slight clinical symptoms.

The frequency of sterility of women due to gonorrhea is variously estimated by different investigators. Glunder found that in 87 sterile marriages 62 or 71.3 per cent. were chargeable to gonorrhea, and Noeggerath found the same in 49 out of 81 marriages. Bumm estimates that 30 per cent. of all gonorrheal patients are sterile. In the 120 patients that came under my observation for the treatment of sterility, I find that 85, or 82 per cent., of the husbands admitted having been treated for gonorrhea for a period ranging from six weeks to two years. Eighteen had double epididymitis, with absolute sterility; 21 had single epididymitis, with absolute sterility in 9 instances; 19 gave a history of prostatitis and seminal vesiculitis, 6 of whom were operated on for stricture of the urethra, and 3 of whom suffered from azoospermia; the remaining 27 evidently had anterior urethritis only, and in all spermatozoa were found. In the majority of cases in which the specific infection involved the posterior uretha and the adnexa there occur exacerbations, which are mistaken by the patient as a new infection. Usually these patients consider themselves cured as soon as the discharge from the urethra subsides. These patients ought to be fully informed of the true pathological state, so that they should not rush into matrimony. I know of a number of quite intelligent men whose wives suffered from primary sterility, who would not have married if they had been informed that they were suffering from an incurable specific infection. Not only is it the duty of the physician to warn the future husband of the danger his future wife is exposed to, but the law ought to be modified to the extent that the physician should be released from the obligation of the medical secret in these cases. For the safeguard of society the physician ought to be allowed legally to report those venereal diseases which Morrow has aptly said do not exist "officially."

Egbert H. Grandin, in his appeal for the safeguarding of marriage from venereal disease, said: "Until the so-called medical secret is relegated to the ash heap of other superstitions, marriage cannot be safeguarded against the venereal diseases. This secret was born to protect the guilty at the expense of the innocent. Therefore, too, it makes of the physician an accomplice. Let us see how it works. Examples fortify facts. A young man, about to enter the state of matrimony, consults me because he has acquired the clap. I warn him against marriage until cured. I tell him of the dangers to health, to life, to which he, in all probability, will otherwise subject his wife. Possibly my interests are keener because I have reared this girl from birth. He declines my advice. The medical secret bars me from telling the parents, or the girl herself. I morally condone a crime. The pure girl, in loving faith, must link her destiny with the impure. A married man comes to me with the infectious lesion of pox. I warn him conscientiously of the danger he is to his wife and to others. He may not heed me. Usually he is too much of a moral coward to tell his wife. Because of the medical secret I cannot. The trusting wife must be inoculated by the 'fond' husband." Have there ever been truer words spoken? I believe it is the duty of the medical man, individually, and of medical societies in particular, to raise this question as a matter of public protection. The general public must be made familiar with existing conditions. They have a good deal at stake, and if a proper campaign of education is carried on it will be finally crowned with success.

Varicocele and non-descended testicles very often account for sterility in the male. Three patients suffered from varicocele. In one patient the removal of this cured sterility of six years' standing. Had this condition been discovered earlier the wife would have been spared the trouble of undergoing need-

less operations. All the patients had azoospermia before the operation. Spermatozoa were found in all three cases three weeks after the operation. Two of these patients were operated upon by Dr. Henry Roth, at the Lebanon Hospital. Non-descended testicles, with accompanying azoospermia, were found in four of this series. They are not amenable to treatment. There seems to be an atrophy of the glandular structure of the testicle and the formation of spermatozoa cannot take place. One patient was operated upon, but the sterility was not cured.

In the course of our work we find that a small proportion of husbands suffer from azoospermia and oligospermia, which cannot be accounted for pathologically, and of necessity are classified as functional disturbances only. Closer inquiry brings out the fact that usually these patients have been excessively masturbating for a long period of time, with the result that the glandular structure of the testicles cannot supply the demand made upon them. The general condition of the patient becomes debilitated. Some of these patients continue to masturbate even after marriage. These patients must be instructed to stop all sexual excitement for a definite period of time. They must be made to follow out the instructions explicitly. They usually improve under properly instituted treatment.

Absolute impotence was found in three patients, two as the result of organic specific disease, one as the result of excessive masturbation. Temporary and relative impotence is frequently found among those who marry at an older age, but with proper treatment they usually improve. The wives of the three patients who suffered from absolute impotence had the hymen intact four, seven and one-half, and 13 months after marriage.

Local Examination and Diagnosis.—The three most important symptoms in gynecology are pain, bleeding, and leucorrhea. All are present in nearly seventy-five per cent. of patients who are sterile, leucorrhea and pain in nearly ninety per cent. The vaginal discharge almost always present is a very important factor in the production of sterility. Aside from its being the result of some inflammatory process, it acts as a mechanical barrier to the spermatozoa, particularly if a thick tenacious discharge plugs the cervical canal. The endocervicitis usually found in these patients must be treated first before any operative procedure is undertaken. Patients whose husbands had had gonorrhea all had a leucorrheal discharge. In most of them a classical history of the time of infection could be easily traced. The appearance of a profuse greenish vaginal discharge, painful and frequent micturition, the sudden appearance of pain during intercourse may be set as the time the infection began to develop. It usually reached its height in about six to eight weeks after marriage. Whether this infection would travel beyond the internal os and involve the uterus and adnexa or not is the deciding factor as to the future sterility of the woman.

The diagnosis as to the cause of sterility in the individual patient is usually very difficult. Once spermatozoa are present in the seminal fluid of the husband, one must assume the woman to be at fault. There are many pathological factors that enter into the etiology of primary sterility that one is unable definitely to outline, particularly in the class of patients who were infected with gonorrhea and suffered from a chronic inflammatory process. We are unable to know with any amount of certainty whether the infectious inflammation did not damage the lining membrane of the tube and cause the ostium to be closed. Adhesion might have been produced which constricted the tubes at some portion. The degree of endometritis that resulted from the gonorrheal inflammation is also uncertain. These and other factors make the prognosis in this class of cases very uncertain. Very often more than one factor in a given case of sterility will present itself, for instance, extreme anteflexion with a history of infection, or a congenital small corpus uteri with a long stenosed and anteflexed cervix, so that one is unable to decide what particular factor is responsible for the sterility. Every one has witnessed the complications which arise when operative procedures are undertaken in the presence of old chronic inflammatory processes of the genital tract. Not only are the patients not cured, but they are exposed to the gravest danger. Many a pyosalpinx and pelvic peritonitis result from simple dilatation and curettage.

It is absolutely certain that nearly 60 per cent. of women who suffer from primary sterility give evidence of gonorrheal infection. The older investigators like Brunenberg, Biegel, Grunewaldt, and Kohrer in an analysis of their cases found fully 40 per cent. to suffer from inflammatory processes. Later investigators like Olshausen, Chrobak, and Rosthorn maintain that the percentage is still greater. I found positive evidence of various degrees of inflammatory processes in sixty-four patients. I am convinced that were it possible to make a thorough bacteriological and microscopical examination in every patient in whom infection was suspected the proportion would be still greater. The diagnosis in this series of cases is mainly based on clinical evidence. In a number of cases the clinical evidence was confirmed by the finding of the gonococcus in smears taken from the cervical secretion. One is likely to find the cause of infection in recently infected patients, but in cases of long standing the gonococcus as a rule is not found, although it surely is the cause of the inflammation. Palmer Findley states that in one case he found the gonococcus only after taking a dozen smears. We all know how difficult it is to carry this out in private practice and in the usual routine of dispensary work.

Next to the inflammatory processes the various displacements of the corpus and cervix uteri are the most important etiological factors in primary sterility. Formerly it was thought to be the main cause. Marion Sims, who propounded the mechanical theory, maintained that 85 per cent. of all cases of primary sterility are due to the elongated, anteflexed, and stenosed cervix. Later investigations entirely disprove his theory, so that Kehrer gives stenosis of the cervix as the cause for sterility in 8 per cent., Chrobak in 6 per cent., Müller in 4 per cent., and Kisch in 7 per cent. of cases. Strassmann, Olshausen, Meckenrodt, and Kisch still further state that in the cases of stenosis of the cervical os it is not purely the stenosed condition of the os which prevents conception, but it is the retention of the secretion in the cervical canal which hinders the spermatozoa from passing through it. It seems very reasonable to assume this to be true in many cases. Of all the displacements acute anteflexion is the one predominating. It seems that the fixed condition of the cervix anteriorly, accompanied as it usually is by the long posterior vaginal wall, interferes to a great extent with the travel of the spermatozoa. Retroflexion bears the same rela-

tion as far as the mechanical obstruction is concerned, but the proportion of cases is very much smaller. Both anteflexion of the cervix and retroflexion of the body seem to be a lack of development on the part of the uterus, probably arrested in its growth after puberty. Usually these two conditions are found in women who have pursued a sedentary occupation for a long time. In this series marked anteflexion of the cervix was met with in 22 patients, lesser degrees of flexion in 14, anteflexion of the body in 9, retroflexion of the body in 3 patients, retroversion in 6, lateral version in 2. In all, fifty-six patients had some abnormal position either of the cervix or of the body of the uterus. Notwithstanding the fact that the displacements play an important factor in sterility, very often patients are seen with most marked anteflexions who become pregnant. It seems that no displacement is an absolute barrier to pregnancy unless it is associated with a constant cervical discharge, and even then one is not absolutely certain, as proved by the cases of Winckel, Olshausen, and Holst, who noticed pregnancy take place in the presence of intrauterine stem pessaries, or the case of Scanzoni in which pregnancy occurred in the presence of a polypus occupying the entire cervical canal. Only when the displacement is associated with severe dysmenorrhea of the mechanical type may we assume that there is probably an obstruction at the internal os and that the spermatozoa cannot pass.

Infantile Uterus.—Unless this is associated with other conditions that point to a lack of development of the genital organs, one is unable to establish a positive diagnosis. A small uterus is only a relative term. I have seen women in whom the uteri were very small and undeveloped who have conceived and have gone through a normal pregnancy. In all my clinical experience I have only seen three patients who had distinct infantile uteri. They were sterile but had associated conditions to help to establish the diagnosis. Their menstrual history was typical of the condition. In one menstruation set in at the age of nineteen, occurred irregularly every seven to nine weeks for two days at the time, and disappeared at the age of twenty-two. In the second patient menstruation appeared at the age of seventeen, was irregular, very painful, and scanty. Sometimes a white discharge appeared instead of the menstrual blood. The vagina was very small. The third patient began to menstruate at the age of eighteen; she is now twenty-eight years old and has only menstruated ten times, the flow lasting two to two and one-half days. She has no dysmenorrhea, but of late she has begun to suffer from hot flushes, dizzy spells, and the sudden rush of blood to the head, all symptoms of the menopause.

Fibromyoma and Simple Ovarian Cysts.—Four patients suffered from fibroid growth of the wall of uterus. They all married at the age of twenty-five or above. One patient was thirty-four years old at the time of her marriage. None complained of any undue symptoms except that the menstrual flow was prolonged to seven or eight days and at times was quite profuse. Sterility is very common in women who suffer from fibroids of the uterus. The proportion who are absolutely sterile will depend upon the location of the tumor. The statistics of Hoffmeier and Scharler show that in myoma of the cervix 18.70 per cent. are sterile, in interstitial fibromyoma 24.7 per cent., in the submucous variety 38.8 per cent., in the subserous fibroid tumors, 47.8 per cent., and in the polypusmyoma variety only 9 per cent. As a general rule the percentage of sterility in fibromyoma of the uterus is not much greater than in other gynecological conditions. Hofmeier and Pfannenstiel found that only 20 per cent. of women suffering from fibroid growths of the uterus are sterile and 15.2 per cent. in other gynecological patients.

Two patients suffered from ovarian cysts, one bilateral the other unilateral. In both patients the tumors were removed. In the patient who had a unilateral cyst the other ovary showed signs of cystic degeneration and was partially resected; however, she never became pregnant. Usually the cysts are unilateral and therefore pregnancy takes place in this class of patients. Even if the other ovary is involved, there is enough ovarian tissue left to perform the function of ovulation.

Sterility of Unknown Origin.—With the advance of modern scientific investigation one is in a position to account for the causes of sterility in the largest percentage of cases. Yet there are a number of patients who came for the treatment of sterility the reason of which cannot be assigned definitely. One inquires into the history of the husband and he is found absolutely well, giving no history of venereal disease, and spermatozoa being found in the semen. The woman is apparently well, with fully developed genital organs functioning properly, and still she is sterile. We are perfectly helpless with this class of patients and must admit our ignorance. It seems that it is not a purely functional disturbance, that there must be either some organic condition along the genital tract of the woman or some derangement in the function of the ovum or spermatozoa, which we do not understand, that prevents impregnation.

The two functions of the uterus are that of giving a permanent resting place for the impregnated ovum, where it begins to develop until it is finally expelled, and that of menstruation. One is usually absent in the presence of the other; very seldom both conditions coexist. Menstruation is a function probably controlled by an internal secretion, although in time the uterus acquires the habit of discharging a certain quantity of blood periodically, a habit which becomes stronger as time goes on. It may be if the impregnated ovum is not firmly settled or not so developed as to counteract the function of menstruation, when the time arrives for the uterus to menstruate, that the impregnated ovum is discharged with the menstrual flow. Theoretically this is very possible; whether this really occurs we do not know. Clinically there is evidence that in many instances a woman who has always menstruated regularly will find herself overdue two to four days. The menses reappear, she notices that she menstruates profusely, that it is of longer duration, and may be more painful. Does this not seem almost like the history of an abortion of a lesser degree? Very often I have been almost certain that pregnancy had taken place, but I had no means by which to prove my suspicion. I believe that as a general rule more abortions take place during the first fourteen days of pregnancy than at any other period. It is very important to have this fact constantly in mind in the treatment of sterility. Fourteen patients in this series belonged to this group. In each instance the husband was perfectly well. The wife showed no pathological lesions and no malformation either congenital or acquired, was physically well developed, and was under thirty years of age.

There was no history of consanguinity except in one patient. No sexual anesthesia, no forced marriage, and no dyspareunia except in a very mild form in two cases. Still they remained sterile and treatment was of no avail. These are the cases that exhaust all our resources. One feels that something is wrong and that something ought to be done for them, but the proper knowledge is lacking and the patients remain uncured.

Treatment.—The question naturally arises when or at what period of married life a woman should be considered sterile, so that proper treatment may be initiated. Duncan and Ansell found that among 9,000 non-sterile women the birth of the first child in seven-eighths of all the women took place at the end of two years; that at the end of the fourth year all except one-thirty-ninth of the women gave birth to children. Duncan put the average time of interval between marriage and the birth of a child as seventeen months; Ansel as sixteen months. Recent authors, including Kisch and Kleinwachter, consider a woman sterile when three years elapse without the birth of a child. Hofmeier, Chrobak, and Rosthorn place this period at two years. I believe that even two years is too long a period from the date of marriage to the birth of a child. There is no reason, physiologically speaking, why this should not occur earlier. If pregnancy does not take place during the first twelve months of married life, the woman should be considered sterile.

In the treatment of sterility one finds that the majority of patients usually seek medical advice chiefly for the relief of two symptoms: sterility and dysmenorrhea. Whatever form of treatment is decided upon should be with the object of relieving both symptoms, and if this is not possible at least the pain accompanying menstruation should be removed. In order to accomplish this no single method of procedure can be applied in every case. Each case of sterility is a law unto itself. The failures in a great many instances are due to the fact that usually one routine method was used.

In the class of patients in whom the sterility is incurable, as when the husband is at fault, the aim should be to cure the severe dysmenorrhea. But one must always remember that the pain in these patients is most probably of inflammatory origin; that there are present in addition to the pain associated lesions, as posterior parametritis, metritis, and possibly a mild form of salpingitis. Operative interference in the presence of inflammatory processes will not cure the patient, but is likely to result in graver pathological lesions. Again there is a class of patients who suffer from mild forms of chronic inflammatory change of the uterus and adnexa which in time will disappear if let alone. Should these women be subjected to any form of an operation, an exacerbation of the old process may take place and the patient is likely to become permanently sterile. Numerous examples of this treatment are well known to every gynecologist. One is, I think, too willing to operate on these patients. The usual procedure of dilatation and curettage surely does more harm than good. As stated above, no single plan of treatment can be applied to all cases. I have endeavored in this series to group the cases according to the method of treatment followed out for the various pathological lesions as they presented themselves.

Group 1 includes all cases in which it was necessary to operate for diseased condition of the adnexa and cervix. Group 2 includes those cases upon whom some form of cervical operation was performed. Group 3 comprises those patients who were treated medicinally only. Group 4 includes those patients who were treated for the relief of dysmenorrhea only. Group 5 includes all other conditions not included in the other divisions.

Group 1.—Nine patients are found in this division. Two were operated upon for the removal of ovarian cysts, one bilateral, the other unilateral. Both remained sterile. Seven patients were suffering from diseased adnexa of chronic nature (cases of pyosalpinx are excluded from this list), and also from severe dysmenorrhea. All were advised operation with the object of curing the sterility. In five patients the tube and ovary on one side were removed and only adhesions separated on the other side. In one patient a cystic ovary bound down by adhesions to the posterior surface of the uterus was removed. The tubes seemed to be normal. One patient was operated upon for the relief of pelvic adhesions. In all these patients the cervix was thoroughly dilated before the abdomen was opened. One patient in this group became pregnant and carried to full term. One conceived but aborted at the end of ten weeks and never became pregnant again. The pain during menstruation entirely disappeared in three patients. Two were relieved and in two the condition remained the same. I feel we are fully justified in advising the woman to have a celiotomy performed for the probable cure of sterility. While it may be the court of last resort, still the patient is entitled to the benefit of doubt as long as she is willing to take the chance. Group 2.—Thirty-six patients were subjected to some form of operation on the cervix. Almost all of these patients suffered from dysmenorrhea. In eleven the old method of Dudley was followed, which consists in incising the posteror lip of the cervix longitudinally to the internal os and inverting the cut ends of the cervix into the angle of the wound. In this way the canal becomes less curved and remains patent. Eighteen had the cervix thoroughly dilated and an intrauterine stem pessary introduced. The pessary was allowed to remain in the cervix from two to six weeks. In cases in which the body of the uterus was very small the pessary was not removed even during menstruation, so as to promote vigorous uterine contraction. In three patients high amputation of the cervix was performed on account of the unusual hypertrophy and cystic formation. The method of Emmet was the one used. In the remaining four simple dilatation of the cervix was performed. The Dudley operation was performed in those cases in which the cervix was elongated, sharply anteflexed, and the dysmenorrhea most marked. In patients in whom the cervix presented a normal appearance but was more or less anteflexed the pessary was used. In every instance the cervical canal was curetted very thoroughly. The sterility was cured in eleven of the cases, three as a result of the Dudley operation, six in which a pessary was used, one in which simple dilatation only was performed, and one in which the cervix was amputated. The dysmenorrhea was cured in nineteen, improved in five, not cured in twelve. Two patients in whom the dysmenorrhea was not cured became pregnant, one eight, the other eleven months after the operation. One patient developed a pelvic abscess as the result of the operation. I believe that the simple dilatation and pessary operation is probably the best method in the greatest number of cases. It exposes the patient to no risk of

infection. The convalescence is short. The patient is able to get out of bed the following day. The theoretical objection to this type of treatment is the carrying of infection from the vagina into the uterus. The latter is normally a sterile cavity, while the former is often the habitat of numerous cocci and very often not surgically clean. It has also been claimed that the pessary may act as a plug and not allow drainage of the uterine cavity. Clinical experience with these instruments has proved that the dangers have been greatly overestimated (Norris). The dilatation should be thorough. The uterine cavity should be explored. It must not be curetted unless there is an absolute indication, like bleeding or glandular endometritis. A suitable stem pessary should be chosen. It must not be too long. Drains that are too long are quickly expelled. Sometimes you can hold the pessary in place by a retention suture of silkworm gut. The vagina is packed to keep the pessary in place.

Group 3.—Thirty-three patients were treated without surgical aid. Vaginal examination did not disclose any definite pathological lesion in the majority of cases. Nine suffered from ulceration of the cervix. Leucorrhea accompanied these ulcerations. Dysmenorrhea was present in nine cases, but of a mild degree. Three had infantile uteri. The ulcerations on the cervix were treated with astringents and antiseptics. The cervical discharge was cleansed with hydrogen peroxide followed by the application of Churchill's tincture of iodine in the canal. The iodine clears up the discharge better than any other durg. The inflammatory processes about the uterus were treated by pouring warm glycerin into the vagina followed by a packing of gauze powdered with boracic acid. If the vaginal discharge was highly acid sodium bicarbonate was used. Gradual dilatation was used when dysmenorrhea was present. Hot douches of six quarts of normal salt solution two or three times daily was given after the packing of the vagina was removed. The patient was instructed to remove the packing the following morning. A vaginal douche to be effective must be taken in the recumbent position, with the pelvis slightly elevated. The water must be as hot as the patient will bear, stream running slowly. The douche bag must not be higher than six feet above the level of the bed. Normal salt is the best solution. The amount must be at least six quarts. These may appear to be small details, but they are very important if the desired effect is to be obtained. The treatment of these cases is to extend over a long period of time. One must not be discouraged too soon. The patient must be told at the outset not to expect a cure quickly. This holds good more so in ulcerations of the cervix, which heal very slowly, six months sometimes being necessary to cure a slight ulceration. Nine of these patients became pregnant and were absolutely cured. The dysmenorrhea was cured in sixteen, improved in one, and in two unimproved.

Group 4.—All the cases in this group, of which there were twenty-five, were treated for dysmenorrhea only. The husbands of these patients suffered from azoospermia. They all had evidence of inflammatory processes and suffered from severe leucorrheal discharges. Marked posterior parametritis was present in twenty. Fifteen had ulceration of the cervix with eversion of the cervical mucous membrane. Tubal involvement was present in six. Twelve had granular vaginitis indicating chronic gonorrheal infection. This class of patients are not amenable to treatment. The pain is of inflammatory origin. They usually come for treatment too late, and the inflammation has already extended beyond the internal os. The danger of an exacerbation is great and complications may result from any operative interference. If operation is decided upon they must be treated medicinally for some time, the object of the latter being to reduce the inflammation to a minimum. Twelve had the Dudly operation performed. In four the adnexa were removed for chronic inflammation. Nine had dilatation of the cervix and four dilatation with the use of a stem pessary. Twelve were cured, two improved, six unimproved, and five did not report and the result is unknown. The treatment in this class of patients must be continued for some time after the operation. They usually improve as soon as better drainage from the uterus is established.

Group 5.—Under this heading I classed all the cases of sterility in which infection and mechanical obstruction of the cervix could be excluded. Seventeen belonged to this class. Three suffered from vaginismus, two had dysmenorrhea at the end of the menstrual flow which disappeared with the improvement of the general condition. The husbands of all these patients were in perfect health. The genital organs were normal, except in one; all remained sterile. The reason for the sterile condition in this group of cases cannot be scientifically accounted for. There must have been some underlying factors which I could not detect or which were not discernible. I cannot conceive why a wife and husband both apparently well, neither giving evidence of any pathological process either congenital or acquired, should not be capable of reproduction. There must exist certain facts either in the physiology or the pathology affecting the genital organs of the human race of which we are entirely ignorant. Further investigation of the physiology of the ovum and spermatozoa will be necessary to clear up many of these conditions. The natural life of the average spermatozoon is unknown. It is probable that certain secretions of the genital tract destroy or devitalize the spermatozoa. Of course this is mere speculation. That a further understanding is necessary in the study of primary sterility is shown by the fact that in over 10 per cent. of our patients we are unable to account scientifically for the sterile condition.

Summary.—1. Sterility was due to inflammatory processes of gonorrheal origin in fully 70 per cent. of the cases. 2. Dysmenorrhea was present in 84 per cent. of the patients. 3. Sterility was cured in twenty-two patients, or 18.3 per cent. If those women whose husbands are sterile be excluded a cure was accomplished in nearly 28 per cent. of the cases. 4. Dysmenorrhea was cured in 56 per cent. and relieved in 10 per cent. of the patients. 5. Displacements of the uterus are not great factors in the production of sterility, and seldom does pure mechanical obstruction cause sterility. It is the stenosis of the cervical canal produced by endocervicitis that prevents conception. 6. Sedentary occupation in early adult life is the most important cause for the various flexions of the body and cervix of the uterus. 7. Leucorrhea was present in 95 per cent. of the patients and in 20 per cent. the reaction was highly acid. 8. The small or infantile uterus, unless associated with other conditions pointing to congenital maldevelopment, seldom, if ever, causes sterility. 9. In nearly 12 per cent. of cases of primary sterility one is unable to account for it either in the

husband or wife. 10. Seventy per cent. of the husbands of women who suffer from sterility have had gonorrhea, and in 40 per cent. the infection extends to the posterior urethra and neighboring structures and is incurable. 11. Thirty per cent. of men who were infected with gonorrhea suffer from azoospermia. 12. The best operative results were obtained by the dilatation and stem pessary method in cases that had not suffered from severe dysmenorrhea. 13. The Dudley operation did not cure the severe forms of dysmenorrhea. 14. Plastic operations on the tubes and ovaries do not give much hope for the cure of primary sterility.

Conclusions.—1. The prognosis for the cure of sterility is unfavorable; one must not hold out too much hope for the patient; 80 per cent. of the patients remain uncured. 2. Dysmenorrhea can be cured in the largest number of cases, but one must be careful in choosing the method of operation. One that will accomplish a cure in one class of patients will not do so in another. 3. The greatest single factor in the production of sterility is gonorrhea and its complications. 4. A goodly number of cases require medical treatment only and as soon as the cervical discharge is cleared up conception is likely to take place. 5. Pathological lesions in the genital tracts of both husband and wife may in time disappear and therefore one must never give an absolutely unfavorable prognosis unless the husband is suffering from aspermia.

I am fully aware that I have not touched upon all phases of primary sterility; this has not been the intention at this time. I have only attempted to bring out a few important points as they were met in the course of treatment of this series of 120 patients. Any symptom or sign that was not found in these patients was purposely left out of the discussion, any mode of treatment that was not followed was omitted. The subject presents such a wide range of study that a complete presentation of it is well-nigh impossible. If I have succeeded in pointing out a few of the principles governing the etiology, symptomatology, and treatment of primary sterility in women I shall be fully rewarded for my effort. If my failures as pointed out will prompt others to make further investigations I feel that I shall have done much for these unfortunate women who come knocking at our doors seeking relief for the barren condition and yearning for the blessings of motherhood. Heretofore we have not been equal to our calling in this respect.

154 Henry Street.

EPIDEMIC POLIOMYELITIS.*

By EDWARD E. MAYER, M.D.,
PITTSBURG, PA.
CLINICAL PROFESSOR OF NEUROLOGY, UNIVERSITY OF PITTSBURG.

In responding to your invitation to speak to you this evening upon the disease which is variously known as acute anterior poliomyelitis, infantile spinal paralysis, Heine-Medin's disease, epidemic spinal paralysis, meningoencephalomyelitis, or acute infectious encephalomyelitis, I do so with full consciousness of having practically nothing to offer which is not found in the voluminous literature upon this disease. Nor shall I attempt to abstract the information one can thus glean, but rather shall largely confine myself to a consideration of what is most important to the general practitioner. I shall therefore not discuss its history, its infectious and variable contagious nature,* nor the monumental work of the last two years which has almost placed in our grasp the nature of the filterable organism, transmissible to the monkey, which causes this disease.

Recent pathological research has also emphasized the fact that we are dealing with a general toxemia with cloudy swelling of the parenchyma of the different viscera. The virus has a particular predilection for nervous tissue, especially the anterior horns of the spinal cord, but meninges and encephalon are by no means exempt from its ravages. In the spinal cord we find a congestion and perivascular collection of cells, mostly lymphocytes and a few polymorphonuclear leucocytes with edema in the interstitial spaces, rapidly followed by focal or diffuse infiltration of cells with or without hemorrhages and accompanied by destruction of both neuroglia and ganglion cells. (Robertson and Chesley: *Archives of Internal Medicine,* Vol. 6, No. 3, September 15, 1910.)

The early diagnosis of this disease is highly important, though not always easy. I might remark here that we do know that the main portal of infection is by way of the nasal mucous membrane, though not justifying, unless from other evidence, the opinion of E. D. Spear of Boston, in a personal letter to me, that "the source of infection is Luschka's tonsil in the nasopharyx and that direct sterilization of this with H_2O_2 (10 volume solution) on a small cotton carrier through the nose will suffice to abort most cases before the stage of paralysis."

The symptom which, amid gastrointestinal disturbance, rigors, fever, or rash, marks the initial stage of the disease, and which stands out prominently, is the early and extreme prostration. Absolute helplessness, with intact sensorium (except in the cerebral variety) before there is any indication of paralysis, a helplessness out of proportion to the gastrointestinal symptoms or the febrile state, is common with sufferers from this disease. The extremities, while not paralyzed, are heavy and lifeless, and often the reflexes will be found diminished and even lost before paralysis is noticed. This also occurs in abortive types without paralysis. This great prostration is, I find, often regarded as paralysis, hence some of the miraculous recoveries. A myasthenic reaction to the electrical current I have also found present in one patient at this stage. That these symptoms as evidences of disappearing tonicity can occur before there is lost function is easily understood. Profuse sweating is also noted early, perhaps also due to the great debility. I have never been able to detect a characteristic odor or a peculiar fetor of the breath, as claimed by some observers. Pain of varying intensity is very frequently present from the first, more or less neuritis being a feature of the disease. Slight nuchal rigidity is almost invariably present and may sometimes reach the intensity of that noticed in meningitis. This nuchal rigidity is more the result of pain and hyperesthesia than of muscle contractions. Herpes zoster has never or rarely been noticed, though *a priori* one would expect to see it fairly often. Intense restlessness generally accompanies the later stages of the disease, as the prostration and stupor mask it at first. Kernig's

*Read before the McKeesport, Pa., Academy of Medicine, October 28, 1910.

*A disease of the colder countries, occurring especially in the hot season, perhaps more so in regions where special soil conditions prevail, are important considerations in the etiology.

sign of an imperfect type is likewise occasionally noticed. Hyperesthesia is present in practically all cases, and a dysuria and in a few instances anuria occur. A rapid tremor, almost fibrillary, is a symptom early present in not a few instances. I have also seen the mottled-like erythema reported by others and in one case the patient was covered with pustules very similar to those of early smallpox. The surface coldness is quite characteristic, though not pronounced, early in the disease, so much so that in very young children we can later, with a thermoesthesiometer, measure fairly well the extent of paralysis thereby, better at least than with the electric battery. Symptoms may vary greatly, according to the type. Wickman's classification, which follows, is valuable: (1) Spinal poliomyelitis type. (2) Ascending form. (3) Bulbar or pontine form. (4) Cerebral or encephalitic form. (5) Ataxic form. (6) Polyneuritic form. (7) Meningitic form. (8) Abortive form.

I have been interested for several years in the blood changes of this disease, and have satisfied myself that there is a slight leucopenia in these patients, occurring very early, a fact observed by others also. Lymphocytosis is also found early and is important because it is a constitutional reaction which tells you that you are dealing with a serious infectious disease and not a simple temporary disorder. I have also tried to determine from repeated examinations later on in the disease the cessation of active symptoms, and until the lymphocytosis recedes to nearly what I consider a normal percentage I do not consider the patient ready for vigorous mechanotherapy. To some of you it is superfluous to insist upon frequent blood examinations in order to value them at all, as so many factors exist which give rise to discrepancies in the tabulated results that an average of several blood counts is always advisable. Single laboratory reports are often misleading and practising physicians should train themselves to do their own blood counts.

This lymphocytosis is secondary to the lymphocytosis of the cerebrospinal fluid and an increase of lymphocytes in this fluid with excess of protein is found earlier and is more characteristic than is the blood lymphocytosis. I do not, however, for reasons I have stated elsewhere (*Journal of the American Medical Association*, Vol. 55, No. 16, October 15, 1910, page 1,397) believe that early lumbar puncture in suspected cases is advisable for the general practitioner, though I recognize the importance of Flexner's investigations in this respect. Later, to clear up the diagnosis, it is an invaluable procedure, but here also we must remember that the marked leucocytosis in acute meningitis is replaced by a lymphocytosis when recovery commences and that we find a lymphocytosis in tuberculous and syphilitic inflammations. It might be well to remind ourselves that in pyogenic meningitis we find a high leucocytosis of the blood current and a polymorphonuclear leucocytosis of the cerebrospinal fluid; that in tuberculous meningitis there is a lowered leucocytosis of blood and a mononuclear leucocytosis in the cerebrospinal fluid. Gay and Lucas (*Archives of Internal Medicine*, Vol. 6, No. 3, September 15, 1910) recently confirmed the presence of a leucopenia in the acute stage, with an increase of eosinophiles and lymphocytes upon differential count, and, speaking of the spinal fluid, conclude that it presents more marked and characteristic findings, namely, an increase in the number of cells during incubation and prodromal stages and the early days of the acute period. Mononuclear at first, they are later replaced by polymorphonuclear cells. A fibrin clot appears in the prodromal and early acute stages, but disappears later.

The Early Treatment.—The early treatment of poliomyelitis is largely still a matter of empiricism. What not to do is most important. Not to employ counterirritation, not to use strychnine, not to permit your patient to rest upon the back, should never be forgotten. Absolute rest, elimination, and supportive measures are definitely indicated at present until our laboratory wizards have shown us the way to happier methods. The period of absolute rest is generally not made long enough, as debility and prostration last for many weeks, and some observers even claim that an extension of the paralysis without further fever or other symptoms may occur two to three weeks after the disease has shown itself. Rest in bed is not all. It should mean rest from massage, from electricity, even from passive motion until assured that repair has commenced and that there is no more danger from hemorrhage or edema or secondary thrombosis. Following a suggestion of Oppenheim, Lange of Münich even advises the immediate application of a plaster jacket and claims that this immobilization relieves the pain and distress very much. Rest does not counterindicate even the early use of supports to counteract the overstretching and contractions of muscles and tendons.

Hot baths and hot enemas of sulphate of magnesium are claimed by some to abort the disease. Personally I suggest the use of aspirin or sodium salicylate or pyramidon salicylate, with hexamethylenamin, combined with codeine if the pains are severe, hot cloths applied to the extremities and ice to the head, and suggest the usual dietetic and hygienic procedures advisable in infectious states. A little later hot baths of ten to fifteen minutes' duration one or more times daily relieve the restlessness and pain more than drugs. Castor oil by mouth and olive oil by rectum are generally the best remedies for the constipation. Calomel and soda with succeeding saline treatment stir up the patient unduly and are not advisable for this reason.

The Stage of Recovery.—As soon as paralysis is noticed and the acute symptoms have subsided we must take precautions to help the damaged muscles. Hot sand bags to the feet, or adhesive plaster bandages for drop foot, pulley weights if the knees or hips draw up, glove gauntlets appropriately reinforced according to conditions present, arm slings or iron-wire splints to abduct and extend the arm, and elastic muscles are some of the many simple devices necessary early to counteract relaxation and to oppose contractures. All such measures can and should be resorted to by the physicians in attendance when necessary. The immediate use of a plaster cast bed is also advised, but I do not believe it is in place so early. A wire cradle or other device to keep the bed clothes from the patient and the use of pillows for support are always proper for the first month.

Mechanical Treatment.—After appropriate wire splints or bandages have been applied to counteract contractures and to prevent faulty position of back and extremities, the time has come when we seek to attempt the stimulation of our patient's muscle masses, and when, therefore, the physician must ascertain clearly the location and extent of the paralysis. He must study the electrical reactions

and put his patient through all kinds of maneuvers and movements to determine what muscles do not functionate, and tabulate the segments or metameres from which they arise. What muscles can we exercise in a compensatory manner, as it were, to the paralyzed ones? Which muscles act antagonistically? By what muscles may we perhaps through the central arc stimulate a few fibers even of a disused muscle? Our limitations are many; the exact spinal cells governing single muscles have not been definitely localized, but fortunately there are definite associations in muscles functioning both cortically and segmentally. The biceps, for instance, helps to elevate the arm anteriorly, to flex the forearm, and slightly to supinate it. The pronator teres to some extent, the brachioradialis and the brachialus anticus are associated muscles. Of course, spinal segments subserve movements, not muscles and nerves, just as the brain cortex commands a definite motion which means the use of several muscles and not a single one. The paralysis of a single muscle implies, therefore, that only cell groups in a segment are destroyed, and that the use of contiguous cell groups may promote restoration of motion.

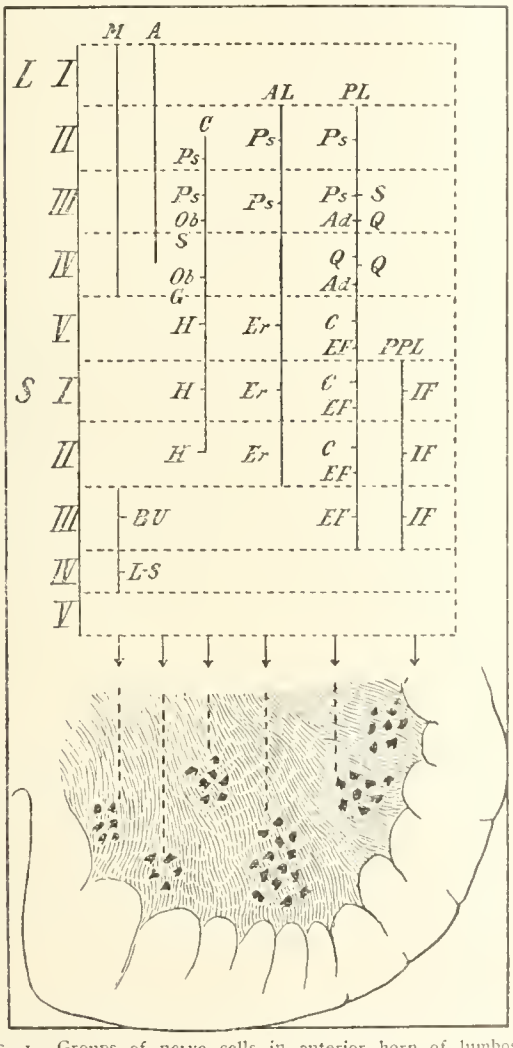

FIG. 1.—Groups of nerve cells in anterior horn of lumbosacral region. Motor function indicated (according to A. Bruce). The lower part of the figure may be regarded as the ground plan, the upper part as the elevation. The lower part of the figure indicates the groups of nerve cells in the anterior horn. The upper shows the vertical extent of these cell groups. The figures to the left and the dotted transverse lines indicate the various lumbar and sacral segments. Cell groups: M, mesial; A, anterior; C, antral; AL, anteriolateral; PL, posterolateral; PPL, post posterolateral. Functions: BU, bladder and uretha; LS, levator and sphincter ani; Ps, psoas and illiacus; Ob, obdurator externus; G, gluteus medium and minimus; H, hamstrings; Er, external rotators of thigh; Ad, adductors; C, calf muscles; EF, extrinsic muscles of foot; S, sartorius; Q, quadriceps; IF, intrinsic muscles of foot.

The following table of Bruce, from "Williamson's Diseases of the Spinal Cord," illustrates this possibility:

Complete clinical records indicating what muscles are paralyzed accompanied in lethal cases by tabulation of what cells and fibers are destroyed will help us to realize this.

We try, therefore, to make our exercise therapy purposeful, in an attempt to compensate or bridge over the lost or inactive musculature. If, for instance, the paralysis is unilateral, we prepare for him exercises which bring into play the same muscles upon the normal side which are paralyzed upon the other, teaching the patient to will impulses at the same time upon the opposite extremity. With children, of course, this and the following methods are not very applicable. A number of forms of apparatus have been devised which fulfill a similar function, the stationary bicycle, for example. A second method is that of imitation, having your patient try and repeat with you or the nurse movements which force him to use the paralyzed muscle. No exercises should be tried to the point of exhaustion or should be employed with faulty posture. In a similar manner we employ electricity, instructing our patient in the effect of opening and closing the circuit and exhorting our patient to attempt by will-power to support the action of the current in the affected muscle or muscles. Used in this way, no one, I believe, can dispute the question of benefit to be derived from the use of electricity, lessening or withholding entirely the current at times to bring out strongly the volitional impulses. Kinetotherapeutic baths I know from personal experience to be a great help in promoting repair of muscular function. The use of hot water itself, it is well known, helps the circulation in the affected limbs and also, on account of the weight of the water, the affected muscles are called upon to do less work in water than out of it. Indeed, movements are often elicited in the bath which are impossible in air. Once the cortical stimulus is again attained, its reproduction naturally becomes easier. One can readily imagine how different the fall of arm or leg when paralyzed is in the air to what it is in water, where time is given sluggish, slightly acting muscles to attempt to do something. The ordinary bath tub, which I have had to employ, is not adapted to all kinds of movements, especially of the trunk, and I have often regretted not having larger tubs, with means to make a patient as comfortable as in a bed in them. The water should be about 95° to 105° temperature; salt may be added to raise the specific gravity of the water, and the length of treatment should be for about ten to thirty minutes. (Not only was I introduced to these methods by the article of Jacob in the *Handbuch der physikalischen Therapie*, Part 1, Vol. 2, but I have abstracted his arrangement in the writing of this paragraph.)

Berry and Desabergh, in the *Albany Medical Annals*, Vol. 31, No. 4, April, 1910, have advocated making exercise a means of play in paralyzed children by considering the arms as wings and the feet as horses, etc. This is wise in very young children (the utilization of various games is not new), but if old enough compensatory exercises modeled upon those of Frenkel for ataxia will be found more helpful, arranging walking chairs, bowling boards, skating models, rowing apparatus, lateral and floor pulleys, ladders, etc., according to the nature of the paralysis. An inverted chair with three rungs for

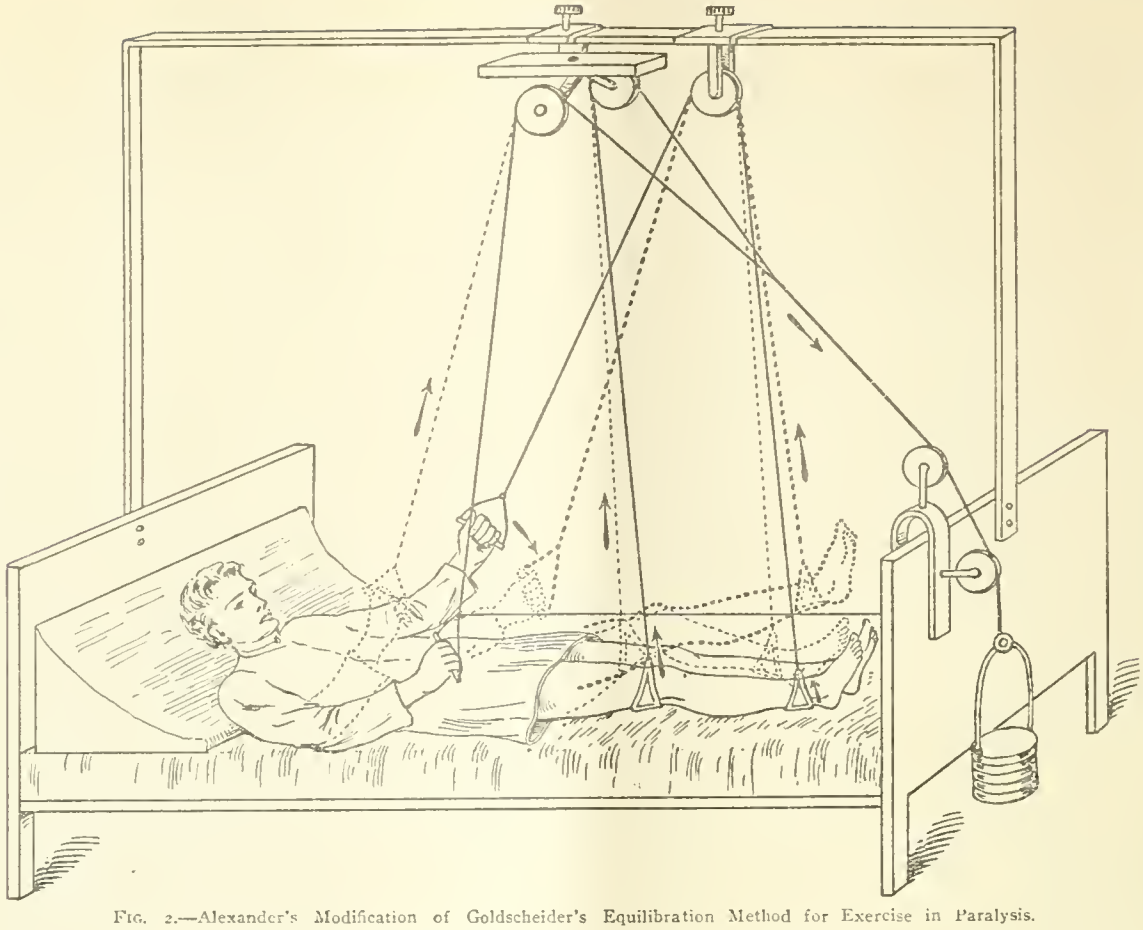

Fig. 2.—Alexander's Modification of Goldscheider's Equilibration Method for Exercise in Paralysis.

bed use has been of great help in developing leg work, also pulleys attached to an upright clamped to the bed or to the adjacent wall, slanting rungs like a ladder fastened to the head of the bed, and other devices have kept patients exercising without being forced on their feet too early. An exercise chair with movable arms and back and an inclined table with stirrup pulleys are two other devices of service after patients are allowed up. These patients are easily exhausted and should not be pushed too hard in the pursuit of healthy muscular action. Later, if available, the various Zander and Herz apparatus may do some good. Exercise adapted to some future occupation or trade must not be forgotten, as time thus spent will serve two purposes.

Breathing exercises for the respiratory muscles should never be forgotten, and they are best done in bed, as are exercises for the abdominal muscles.

Electricity and Massage.—I am one who still believes that the intelligent use of these measures does good if accompanied by the knowledge of what muscles or nerves need thus to be stimulated, and with electricity that it be given in proper dosage and with proper technique. As this is fully treated of in text books, and cannot anyhow be learned except in practice, I need not go into details. I might add that muscle beaters made of a tennis ball attached to an iron wire skewer serve better for massage than rubbing by an inexperienced nurse.

Orthopedic Treatment.—The discussion of tenotomy, arthrodesis, tendon, or muscle transplantation is a matter for the orthopedist, whose domain this is. Until the period of paralytic recovery is past, however, which varies between six months and two years, I do not believe such patients are orthopedic cases unless the physician in attendance is not personally willing and able to search out the muscles affected and to institute the simple mechanical measures indicated for the correction of faulty position, whether due to relaxation or to overaction. Most deformities are due to neglect, and not only prevent recovery of disused muscles, but make later orthopedic treatment most difficult. A consideration of these different procedures will be found fully presented in works on orthopedics and in the recent literature.

A THEORY OF THE ETIOLOGY OF TRACHOMA.

By D. S. KANSTOROOM, M.D.,

That trachoma is the grandchild of malaria has been my theory for the past ten years, and I hereby take the liberty to deliver it to the tender mercies of a bacteriophobic medical world. There are hopeful signs that we are soon to be delivered from the bacteriological bondage which has fettered medical thought for the past twenty-five years about the etiology of trachoma.

Trachoma is considered at present one of the most contagious diseases. The United States government considers it a "dangerously contagious disease," and deports all aliens affected with it. But trachoma is no more contagious than that condition known as adenoids.

The following two propositions embody, in short, my theory of the cause of trachoma:

First. It is a special chronic reaction on the part of the adenoid tissue of the conjunctiva to toxins (malarial, etc.), and autotoxins circulating in the

blood, and to some secondary, local acute, special infections (Koch-Weeks bacillus, diplococcus of Morax-Axenfeld, and the gonococcus), in persons predisposed by racial, hereditary, and climatic causes.

Second. The pathological process of trachoma appears in three distinct stages. First stage found in infancy and characterized by chronic conjunctival congestions and lymphangiectasias. Second stage found in adolescents and characterized by "transient" follicular hypertrophy, commonly known as "follicular conjunctivitis. Third stage found in adults, and characterized by permanent hyperplasia of the conjunctival adenoid tissue, followed by scar formation, commonly known as granulated lids or trachoma.

Trachoma is a disease of civilized people, and is most prevalent in races that have been longest under the baneful influence of civilized life. It is unknown to those races living in primitive ways. The negro race is practically immune against it, and is also resistant to malaria. In malaria we have the solution of the problem of the etiology of trachoma.

Malaria, the pest that wiped out Greece and Rome, and that is eating at the vitals of all civilized people, is really the prime factor in the evolution of that pathological process known as trachoma.

Trachoma is the pathological sequel of malaria, and is the product of the evolutionary development of a lesion in those races that had suffered from it for many centuries. The geographical distribution of malaria and of trachoma has always been the same. Where malaria has gained a foothold, trachoma is sure to follow; but not in one day, one year, or one generation.

The effect of chronic autotoxemia, following malarial cachexia, through many succeeding generations will finally resolve itself into that pathological phenomenon known as trachoma. When it is once established as a pathological trait of a race or a family, it will go down as an hereditary predisposition to the succeeding offsprings, who will suffer from it if they follow in the footprints of their ancestors. It is obvious that chronic autotoxemia alone cannot produce trachoma, and that the etiological trinity consists of malarial cachexia, chronic autotoxemia and hereditary predisposition.

How does chronic autotoxemia bring about that pathological process of trachoma, and what is autotoxemia? A. Combes defines it as a toxemia caused by substances which are formed through the influence of the vital processes of the body. It may originate from two different sources: (1) From a qualitative and quantitative deterioration in normal digestion, enzymic and microbic; (2) from an abnormal function of the tissues and incomplete action of the antitoxic glands. The system which guards against autotoxemia is: (1) The intestines, the secretions and excretions found there; (2) the intestinal mucous membrane and the antitoxic glands—the liver, kidneys, suprarenal, thymus, thyroid, and pituitary glands.

All the toxins circulating in the blood are eliminated by (1) The sudoriferous and salivary glands; (2) the respiratory tract and the conjunctiva. One of the specialized functions of all adenoid tissue is the elimination of poisons. The conjunctiva being an adenoid structure, is also concerned in the elimination of poisons circulating in the blood.

In explanation of how chronic autotoxemia causes trachoma, in persons hereditarily predisposed, we assume that the chronic irritation caused by the constant elimination of autotoxins by the conjunctival adenoid tissue brings about that reaction on the part of that tissue which is characterized by the adenoid hypertrophy found in trachoma. Pharyngeal adenoids arise in the same manner.

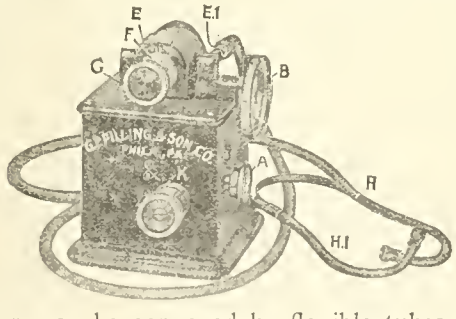
What is it that makes our bacteriophobic friends consider trachoma as a contagious disease? The answer is simple. We know that a tissue chronically inflamed is prone to infection. The conjunctival adenopathy of trachoma being caused by chronic inflammation due to autotoxins, predisposes the conjunctiva to accidental infections. The accidental superadded infection commonly found in trachoma, *viz.*, from the Koch-Weeks bacillus, diplococcus of Morax-Axenfeld, and the gonococcus, gives trachoma its apparent contagious nature.

Norris & Oliver (vol. III, page 212) make the following prophetic statement regarding trachoma: "Trachoma is not a simple local disease due directly to a specific infection by a special germ from the outside, but it is a local manifestation of a dyscrasia." If only this sentence should start the medical world athinking, the delivery from trachoma would be an assured fact.

AN IMPROVEMENT IN AUDIOMETERS.

By FRANCIS A. FAUGHT, M.D.,
PHILADELPHIA.

THE accompanying illustration represents an improvement in audiometers. It measures the acuity of hearing of either ear to the exclusion of the other. The device controlling this being so arranged that it is impossible for the patient to know either the intensity of the sounds or the ear to which the sound is sent. This removes absolutely the danger of mental influence or malingering. The apparatus is based upon the principle that sounds of varying intensity produced within a practically air-tight



chamber may be conveyed by flexible tubes to the ears of the subject, and that these sounds when just audible to the subject will represent his acuity of hearing. It is arranged to vary the intensity of these sounds at will and to throw them into either or both ears. These sounds are produced within the cavity of the apparatus by means of a toothed wheel, A, which operates a balanced hammer striking a tiny bell. Marks on the toothed wheel indicate the time that this sound is produced. The escape of this sound is regulated by the wheel, B, which is graduated in 100 equal parts and controls the size of the orifice through which the sound passes to the ears. The distribution of the sound to either or both ears is controlled by the three-way valve, F. The intensity of the sound is controlled by the set-wheel, K, which regulates the strength of the blow of the hammer upon the bell. This wheel is graduated from zero to ten to facilitate accurate recording. The instrument is approximately four inches square and weighs about seven pounds complete.

New York, February 18, 1911.

DR. STEPHEN SMITH.

THERE are rare occasions in professional life when the workers pause to honor one among their ranks whose life mirrors the ideal physician of the modern metropolis. To-night, at the festal board, a number of friends, lay and medical, render homage to Dr. Stephen Smith, whose long and useful career has been identified with the development of scientific medicine in New York and the nation during six decades.

Born February 19, 1823, he had the good fortune of a childhood spent upon the farm. After the preliminary education of the country school he began the study of medicine at the office of a country practitioner. In 1851 he received his medical degree from the College of Physicians and Surgeons, New York, and for the following sixty years his professional life has comprised every form of dignified activity open to the enlightened physician. Associated with Bellevue Hospital for nearly twenty-six years as interne, attending surgeon, professor of surgery, professor of anatomy, and to this day as consulting surgeon; and for many years professor of clinical surgery in New York University, and visiting and consulting surgeon to St. Vincent's Hospital, he has been closely linked with the academic life of the Western metropolis.

As medical journalist, as a member of city, State, and national boards of health, as United States Commissioner at the Ninth International Sanitary Conference, as founder and first president of the American Public Health Association, as author of surgical text-books and of many other contributions to medical literature, one beholds in his career a perfect fulfillment of the ideal of the modern physician—service to science, to the State, and to the public. His is the enviable glory of an old age crowning a life of eminent achievement.

RECENT INVESTIGATIONS ON THE DUCTLESS GLANDS.

THE subject of the mutual relationship of the ductless glands and of the effects of the administration of extracts of the latter to the human being under normal and pathological conditions has for a long time engaged the attention of W. Falta, L. H. Newburgh, and E. Nobel. In their latest communication in the *Zeitschrift für klinische Medizin*, Vol. 72, Nos. 1 and 2, these investigators publish the results of an extensive series of experiments that have an important bearing on clinical and therapeutic problems. These problems concern chiefly the question of the parallelism in action of the various glandular extracts and of the relation of these extracts to one another.

The subcutaneous injection of adrenalin causes quite regularly a slowly rising and long persisting increase of blood pressure. At the same time the pulse rate is accelerated, although occasionally diminished in the beginning, while sometimes arrhythmia occurs. The glycosuric action of adrenalin is not parallel to its pressor effect. If the former is not produced it may be elicited most frequently by the preliminary administration of atropine. The synchronous administration of pilocarpine inhibits the glycosuric effect of adrenalin. Neither atropine nor pilocarpine has any perceptible effect on alimentary glycosuria. It is thus seen that adrenalin glycosuria and alimentary glycosuria are not parallel processes. In the nonglycosuric stage of diabetes mellitus adrenalin as a rule does not produce glycosuria, but this is increased, when present, together with the elimination of ketone bodies. This increase occurs even in the presence of the markedly positive action of pilocarpine, and is independent of an increased diuresis. In acute tetany adrenalin evokes the phenomena of the acute attack, together with an abnormally rapid and sharp reaction of the cardiovascular apparatus and with no glycosuria. In cases of latent tetany the circulatory effects are slight and glycosuria usually occurs. The diuretic action of adrenalin is not parallel with its glycosuric and pressor effects.

Equally important are the observations made relative to the action of thyroidin. When administered by mouth this substance causes quite regularly an acceleration of the pulse and increased blood pressure, together with other symptoms of clinical hyperthyroidism. This increased blood pressure is also produced in diabetes mellitus, both in its glycosuric and nonglycosuric states. The glycosuric effect of thyroidin is not parallel with that of adrenalin or of pilocarpine. In cases in which adrenalin is incapable of producing glycosuria, the latter may be evoked by the preliminary administration of thyroidin. In normal individuals and in cases of hyperthyroidism thyroidin increases the number of uninuclear cells, while in hypothyroidism it increases the number of neutrophiles.

As regards the third of the great ductless glands, namely, the pituitary body, it is noted that the extract of the infundibular portion causes a pronounced diuresis, which is an effect parallel to that resulting from the administration of adrenalin. Moreover, the teachings of Eppinger, Falta, and Rudinger regarding the functional correspondence of the thyroid, pancreas, and chromaffin system are confirmed and extended. The clinical syndromes evoked by adrenalin or thyroidin are composed of many varying components. The nature of the particular syndrome produced differs with each individual, and is apparently associated with a certain constitutional factor as yet unknown.

THE PATHOLOGY OF THE "ONLY" CHILD.

The moralist, the educational expert, and the publicist have each pointed out the disadvantages associated with a childhood spent amid the solitude of a home in which there are no other children. These disadvantages concern not only the future welfare of the child but also the integrity of the family and of the race. The domestic isolation of the child accounts for important defects in its ethical and intellectual development. Moreover, the danger of racial deterioration resulting from limitation of offspring has, in many parts of the world, become a problem of national importance. But another phase of this question has apparently escaped attention, namely, the relative morbidity of the "only" child.

With the characteristic ingenuity with which Teutonic writers have explored the outlying districts of medical research, this problem has recently been approached by J. Friedjung, who reported his results before the Pediatric Section of the Society of Internal Medicine and Pediatrics, in Vienna, November 10, 1910. His observations were made on 100 children, 45 boys and 55 girls, of ages ranging from two to ten years. Of these there were 18 characterized as severely neuropathic, and 69 as slightly neuropathic, and only 13 were fully normal. In contrast to these observations, it was found that among 100 children belonging to families containing several offspring, only 31 were neuropathic. The nervous phenomena were of a neurasthenic and hysterical nature. The emotion of fear was conspicuous in 75 of the 87 neuropathic children. In 49 there was restless sleep, and in 8 pavor nocturnus. Waywardness and unusual mental ability went hand in hand. In 32 children there was a remarkable degree of malnutrition resulting from the obstinate anorexia which was present in 50 children. In 37 there was habitual vomiting, in 20 chronic constipation, while in others there was recurrent neuropathic colitis. In 48 children there was urticaria and in 29 a severe pruritus. The author attributes these morbid manifestations to the excess of tender care which these children receive, which conclusion suggests the proper prophylaxis and therapy.

PROGRESS OF OUR KNOWLEDGE IN TROPICAL AFFECTIONS.

Many summaries of this subject have recently appeared in certain journals, notably those whose countries represent large colonial possessions. Thus Hoffmann in the first issue of the *Berliner klinische Wochenschrift* for the current year gives a general summary of what is being done in tropical countries in nosography, hygiene, and treatment. The reason for this interest is plain: disease in the tropics means more than disease in temperate regions. New diseases constantly come to light; old scourges are ever coming into new prominence. Hoffmann himself is connected with the marine hospital service, through which he must be in touch with all that concerns ship diseases, diseases of soldiers, and the like. The subjects of acclimation of foreigners and hygiene among the aborigines may be left out of consideration for the time being. The author proceeds at once to the subject of warfare against actual tropical diseases. Malaria comes first. This affection claims over 1,000,000 victims annually in India, and this figure exhibits menace in all warm climates. In the antimosquito campaign much good has been achieved, chiefly by Italians, who, as a temperate or sub-tropical race have reduced the mortality to one-third. At the same time the sale of quinine as a state monopoly has yielded 600,000 lire annually.

For trypanomiasis, meaning chiefly sleeping sickness, atoxyl is still unsurpassed as a remedy; substitutes are insufficient for cure and have unpleasant after effects. Chagas found a new form of human trypanosomias in Brazil, the intermediary being the "big bed bug." Unfortunately studies in this subject have been interrupted. Trypanosomata appear to be able to circulate in the blood in the temperate zones without causing illness. The celebrated Oriental boil, known under a host of names, is now fully known to be due to the presence of a protozoan organism, *Leishmania tropica*. A similar agency is responsible for a variety of other infections, including Kala-azar of India, and possibly also the affection known in Greece as Ponos. Pellagra is now believed by many to be due to the propagation of a specific germ through a species of crawling gnat, the *simulium*.

Progress of our knowledge in yellow fever has not been satisfactory, but destruction of the *Stegomyia fasciata* has led to brilliant results. As yet we do not know the ultramicroscopic cause of the disease. Prouazek, the eminent student of protozoa, seems to have found the exciting cause of smallpox in Brazil. The disease seems to be largely flea borne. Progress in our knowledge of beriberi seems for the present largely at a standstill. Relapsing fever is a spirochete disease, due to a protozoan and transmitted in part by insects. Atoxyl and the Ehrlich-Hatta 606 have both shown power over it. Yaws seems to be for practical purposes a form of syphilis, curable by 606. Tropical dysentery seems to be spread by cats.

Various scourges, cholera, plague, etc., cannot be dismissed so summarily. The mortality of cholera is tremendous and cannot be settled offhand by a mere phrase. Saline infusion is the only hope held out, now as nearly a century ago. We know the cause of this affection, the *chobra orbris*, but as yet are unable to attack it with any force. Plague is even less amenable to treatment. Although its pathogenesis is well known, it nevertheless stands a good chance of being adopted among the domestic diseases. It never was peculiar to the tropics. The nature of Malta fever is still unapparent, according to Hoffmann, although its cause is well known. There is possibly some relation between it and typhus fever, for the serum of one appears to agglutinate against the other. Space forbids further abstraction from Hoffmann's article. Many conditions confined to small localities, and having a relatively small coincidence, are not mentioned, such, for example, as the verrugas of Peru, and certain distinctive blastomycoses.

The Position of Ship Surgeons.

The lot of the medical officer of the mercantile marine is like that of the policeman, not always a happy one. In an article on this subject, published nearly ten years ago, we pointed out that every British passenger-carrying steamer of a certain capacity was compelled to carry a medical officer whom the companies paid a pittance of $40 to $60 a month. The German and other European boats paid their medical officers less, while on American ships the position of the surgeon was said to be even worse. That matters in this respect have not altered much for the better in British ships is shown by the fact that an agitation is again being carried on in the correspondence pages of the *British Medical Journal*, having as its object the betterment of the position of the ship surgeon. It was at first urged that the companies be persuaded or compelled by the pressure of public opinion to raise the salaries and improve the accommodation provided for these necessary officers. Dr. Rentoul, however, writing in the issue of October 15, 1910, advocated the method of improving the ship doctor's position by means of collecting fees for medical attendance from the passengers who have benefited thereby rather than by demanding increased salaries from the ship owner. A somewhat similar suggestion was made in the Medical Record in the article above referred to. According to Dr. P. Heywood Hadfield, on one of the British lines running to the Far East and Australia in the first and second saloons the medical officers are empowered to charge fees for the services on an authorized scale. The scale is a low one, but it is urged that a doctor at sea, who has not to keep up a house and has no expense of transport, should not be expected to receive fees equivalent to those charged ashore. However, the question is not so much the size of the fee as that the principle is established that saloon passengers are no longer to expect at sea free medical treatment. There is no reason why a passenger should not pay for his medical attendance afloat as well as ashore.

Syphilis as the Etiological Factor in General Paresis.

Differences of opinion as to the causation of general paresis have existed for some time. In recent years the views of the medical profession have been veering to the belief that the chief etiological factor in general paresis is syphilis. Statistics gathered from insane asylums have tended to confirm these views. Charles K. Clark, superintendent of the Toronto Asylum for the Insane, lecturing on the subject in Toronto on November 19 supported these opinions. Clark has compiled statistics with regard to general paralysis in the asylums for the insane of Ontario during a considerable period of time. The tests employed have been examinations of the cerebrospinal fluid. Noguchi's test is used as well as a test devised by Ernest Jones of Toronto, which consists in adding to the cerebrospinal fluid a concentrated solution of ammonium sulphate. When there is a positive reaction a white ring appears at the junction of the fluids. Should either of these tests prove positive and the Wassermann reaction be also found, it is taken for granted that the patient has a previous syphilitic history. It is said that these methods have been the means of showing that 100 per cent. of the cases in Toronto Asylum have a history of syphilis.

News of the Week.

Health of the Canal Zone.—For the month of November, 1910, the Department of Sanitation of the Isthmian Canal Commission reports among employees a total of sixty deaths, of which forty-three were due to disease and seventeen to external causes; this making an annual average from all causes of 14.92 per thousand. For the past few years the death rate during November has been as follows: 1905, 35.45; 1906, 30.61; 1907, 20.66; 1908, 11.50; 1909, 15.27. The annual average death rate per thousand in the cities of Panama and Colon and the Canal Zone for November, including both employees and civil population, was 25.21, which is an increase over the last two years, the rate for 1908 having been 23.71, and for 1909, 19.14. The increase in infant mortality in Panama continues, about 30 per cent. of the total deaths in that city being of children under one year of age. The principal causes of death among the employees during November were: Malarial fever, 3; hemoglobinuric fever, 1; pneumonia, 11; tuberculosis, 7; dysentery, 1; nephritis, 2. There were no deaths from typhoid fever; and no cases of yellow fever, smallpox, or plague originated on the isthmus during the month. One case of yellow fever was removed from a vessel arriving at quarantine from Guayaquil, and the quarantine against that port is being strictly enforced. Cases of plague are also reported from Guayaquil and from Caracas. In the Canal Zone the sanitation work is being steadily carried on, the precautions against the propagation of stegomyia being as thorough now as they were at the time when yellow fever was prevalent. The work has been extended so as to include the native town of Porto Bello, which is in constant communication with the Canal Zone. Conditions during November also favored the control of anopheles and malaria, and the hospital malarial sick rate was very low.

Control of Marriage in Pennsylvania.—A bill has been introduced into the Pennsylvania Legislature forbidding the issuance of marriage licenses to imbeciles, epileptics, and persons of unsound mind, to male paupers, or to persons suffering from transmissible disease or under the influence of alcohol or narcotic drugs. The bill further provides that the marriages of such persons in other states shall be considered void in the State of Pennsylvania.

Antivivisection Bill.—Bill No. 287, introduced into the New York Assembly by Assemblyman Hoey on February 1, for the Antivivisection Society, has been endorsed by the Society for the Prevention of Cruelty to Animals. It reads: "The Governor is hereby authorized to appoint a commission which shall consist of seven members, two of whom shall be physicians or scientific men residing in this State, two of whom shall be active members of some organization of this State having for its purpose the prevention of unnecessary cruelty in vivisection; two of whom shall be lawyers practising within this State, and the remaining member of the commission shall be appointed at large." The bill has been referred to the Assembly Committee of Public Health. The danger of the bill is its apparent harmlessness; it asks merely for an investigation. Yet, as the *New York Times* says, "the passage of a similar measure in Great Britain was followed by a train of consequences that checked medical progress in that kingdom. Had the forces which that investigation let loose in Great Britain

operated on the Continent and in the United States, the cures that have been perfected, and are being perfected, for yellow fever, typhoid, diphtheria, meningitis, pneumonia, tuberculosis, infantile paralysis, cancer, and grave diseases of the blood would have been prevented, and progress in modern surgery would have been achieved at an added sacrifice of human life."

Charitable Bequests.—By the will of the late George Platt of Philadelphia the sum of $8,000 is bequeathed in trust for the benefit of the Wills Eye Hospital. After the death of a sister of the testator the residue of the estate is to be divided, three-twentieths going to the Hahnemann Hospital for the support of free beds, three-twentieths to the Episcopal Hospital, also for free beds; one-tenth to the Hospital of the University of Pennsylvania; one-tenth to the Pennsylvania Hospital, and one-twentieth each to the Philadelphia Orthopedic Hospital, the Children's Hospital, and the Hospital for Diseases of the Lungs at Chestnut Hill.

By the will of the late Elizabeth T. Brown of Philadelphia the sum of $5,000 is bequeathed to the Presbyterian Hospital for the endowment of a free bed in memory of her mother.

The Presbyterian Hospital of New York receives a bequest of $7,500, and the Flushing Hospital, New York, one of $10,000, by the will of the late Mrs. Charlotte Garretson of New Hyde Park, Long Island, who died last month.

The Homeopathic Hospital of Yonkers receives $1,000 and St. John's Hospital $20,000 under the will of the late Mrs. Caroline Lawrence of that city, who died recently.

Dr. Ewald Wins Injunction.—Justice Goff on February 6 granted the injunction asked for by Dr. L. A. Ewald restraining the New York County Medical Society from acting upon charges filed against him, on the ground that he had resigned from the society. The medical society had refused to accept the resignation, but the court held that such a refusal was an attempt on the part of the society to exercise punitive powers which are in excess of its corporate powers, and that a by-law of the society providing that no member under charges can resign is void.

Ambulance Crash.—An ambulance from the Williamsburg Hospital, Brooklyn, N. Y., was overturned on February 8, when the horse drawing it became startled and bolted. The physician in charge, Dr. Elizabeth Bruyn, was severely injured, but, owing largely to her coolness of mind, the patient in the ambulance was unhurt.

To Control Milk Traffic.—A bill was lately introduced into the New York Legislature which provides for the control of the milk traffic in the cities of New York, Buffalo, and Rochester, by the appointment of a commission of three members, who will have supervision of milk dealers, and power to fix standards of quality and price. The bill provides for the licensing of milk dealers by the commission, which is to be appointed by the Governor, the commission also to have the right to inspect plants and examine books and papers at any time and to order yearly reports from all milk dealers.

The Study of Eugenics.—Sir Francis Galton, the English scientist who died last January, has bequeathed a large part of his estate to the University of London for the establishment of a department to encourage the study of national eugenics.

The "Spitting" Crusade.—Since January 1, 160 persons have been arrested for spitting in the subway and elevated stations and on the bridges in New York, the Health Commissioner having inaugurated a campaign against the nuisance. Of the 100 men arrested in January 54 were fined and 36 had their sentences suspended. During the first week of February 40 were fined and 16 sentences were suspended. Of the entire number only 14 were discharged outright.

Straus Plant Accepted.—The United States Senate on February 6 passed the bill authorizing the Secretary of the Treasury to accept the milk depot and laboratory now maintained in Washington by Mr. Nathan Straus and to operate it as a part of the Public Health and Marine-Hospital Service. An appropriation of $15,000 is made for the maintenance of the plant until June 30, 1912, "for the purpose of investigating the practical utility of infants' milk depots in the reduction of infant mortality, and the relative value of pasteurized and raw milk for infant feeding, and for other appropriate scientific purposes." An amendment to the bill provides for the sale or free distribution of the milk at the discretion of the Secretary of the Treasury.

Old Magazines Wanted.—Commissioner Lederle of the New York Department of Health has issued an appeal for donations for the magazines which will be very acceptable for use at the tuberculosis hospitals particularly. Any pictures that could be used for decorating the walls of wards would also be very gladly received, as would also discarded toys. There are now about 260 patients with tuberculosis in the Riverside Hospital and about 400 in the Otisville Sanatorium. Any magazines, pictures, or toys sent to the Department of Health, Sixth avenue and 55th street, in any quantity, will be immediately forwarded to their destination.

Not Yellow Fever.—Reports of the presence of yellow fever on the U. S. gunboat *Marietta* are denied by the quarantine officers who inspected the vessel at Key West. The three suspected cases were diagnosed as malarial fever. The cause of death in the one fatal case was not determined, but probably was also malaria.

New Drug Law.—At a recent meeting the New York Board of Health revised Section 482 of the Sanitary Code, relating to the sale of preparations containing morphine, cocaine, and similar drugs, so that it now reads: "No cocaine or salts of cocaine, eucaine, stovaine, alpha or beta eucaine, either alone or in combination with other substances, or any substance under any other name giving a similar chemical test of cocaine, and no opium or official preparation of opium, and no morphine or salts of morphine or the derivatives of either or any of them, shall be sold at retail by any person in the City of New York except upon the written prescription of a physician duly authorized to practise as such or other person duly authorized by law to practise medicine and administer drugs or perform surgery with the use of instruments. Any such prescription shall not be refilled. Nothing hereinbefore mentioned, however, shall apply to compounded mixtures containing opium or morphine or their derivatives, the formulas for which are given in the latest Dispensatory or National Formulary, in which said mixtures the maximum dose, as plainly stated on the label of the package as dispensed, does not contain in excess of one-half a grain of powdered opium or the equiva-

lent of its alkaloids; or to preparations for external use only in the form of liniments, lotions, ointments, or oleates. The last mentioned preparations shall be labeled 'For External Use Only,' and marked 'Poison.'

School Inspection.—A complete system of medical inspection of public schools is soon to be inaugurated in Pittsburg, involving visits of the corps of physicians to every classroom every other day. A physical census covering the condition of each child will also be made.

The Plague Spreading.—Although the official reports from Pekin report a favorable turn to the situation in China as regards the prevalence of the plague, unofficial sources state that there has been little improvement. The Chinese Government has decided to devote the unspent balance of the fund provided for the entertainment of the German Crown Prince to fighting the epidemic. The Crown Prince's visit was abandoned because of the plague. Unofficial reports have also been received of the arrival of persons suffering from the disease at Penza, Russia. Four fatal cases are also said to have occurred in the Government of Astrakhan, and quarantine against Russia may be instituted by Roumania. In response to the appeal of the Chinese Government, Russia is sending a staff of scientific men to fight the disease in Manchuria.

Vital Statistics.—During the month of January, 1911, 12,057 births were registered in New York, 462 more than were registered during the same month in 1911. This increase in registration, while probably due in part to an increased number of births, is partly due also to the active campaign which the Department of Health has recently been carrying on to secure complete returns of births from physicians and midwives within the ten days required by law. Evidence of the effectiveness of these efforts is furnished by the fact that practically all births are now reported within the time required, while heretofore such returns have been made anywhere from two to three days to two to three months.

The Society for the Suppression of Unnecessary Noises.—The fourth annual meeting of this Society was held on Tuesday evening, February 14, at the residence of the president, Mrs. Isaac L. Rice. Addresses were made by Bishop Greer of the Episcopal Diocese of New York, Dr. Albert Warren Ferris, president of the State Commission in Lunacy; Thomas O'Brien of the Board of Education, Dr. C. Irving Fisher, superintendent of the Presbyterian Hospital, and President George S. Davis of the Normal College. Dr. Fisher spoke of the unnecessary noise made by the ambulances with clanging bells and said that the accidents caused by ambulances had actually been reduced in cases in which the bells had been removed, for the drivers were rendered more cautious. Bishop Greer made a strong plea for a quiet Fourth of July, progress toward which has already been made in New York largely through the efforts of the anti-noise society. The reports showed that the Society had been active during the year in combating the noises of this noisiest of cities, and especially in educating the citizens, particularly the children, up to an appreciation of the blessings of stillness.

American Society of Sanitary and Moral Prophylaxis.—A meeting of this society will be held at the Academy of Medicine on Thursday evening, February 23. The subject for discussion will be "Departmental Control of Venereal Diseases." Papers will be read by Drs. Frederick H. Gerrish of Portland, Me,; Dr. Lucien Howe of Buffalo, and Mr. Wm. A. Purrington.

Philadelphia Neurological Society.—At the annual meeting held on January 27 the following officers were elected for the ensuing year: *President,* Dr. Alfred Reginald Allen; *Vice-Presidents,* Dr. John H. W. Rhein and Dr. Samuel V. Ingham; *Secretary,* Dr. George Price; *Treasurer,* Dr. S. D. Ludlum; *Council,* Dr. James Hendrie Lloyd, Dr. Francis X. Dercum, and Dr. Henry H. Donaldson.

Rochester (N. Y.) Academy of Medicine.—The officers of the Academy of 1911 are as follows: *President,* Dr. Richard M. Moore; *Vice-Presidents,* Dr. John R. Williams, Dr. E. Wood Ruggles, Dr. Arthur W. Thomas, and Dr. Frank P. Leadley; *Secretary,* Dr. William M. Brown; *Treasurer,* Dr. Wesley T. Mulligan. The vice-presidents are the heads respectively of the sections on General Medicine, Surgery, Obstetrics, and Public Health.

The New York Psychoanalytical Society was organized at a meeting held February 12, 1911, at the residence of Dr. A. A. Brill. The following officers were elected: *President,* Dr. A. A. Brill; *Vice-President,* Dr. B. Onuf; *Secretary and Treasurer,* Dr. H. W. Frink, 34 West 83d street, New York. Meetings are to be held on the fourth Tuesday of each month. The society will be incorporated and is to become affiliated with the parent organization in Zurich.

American Gastro-Enterological Association.—The fourteenth annual meeting of the association will be held in Philadelphia on April 19 and 20, 1911, at the Bellevue-Stratford Hotel. Dr. Charles D. Aaron of Detroit is the secretary of the association.

The Late Dr. Janeway.—The Medical Board of the Mount Sinai Hospital, at a meeting held at the hospital on Tuesday, February 14, adopted the following resolutions:

Resolved, That it has learned with great sorrow of the death of one of its most honored members, Dr. E. G. Janeway. By his death the Medical Board has lost a kindly friend and valued councilor, and the hospital has been deprived of the services of an eminent, faithful, and able physician. His association with the hospital has shed luster upon its reputation, and served as a stimulating example in the direction of progress.

It was further resolved to express to the widow and the members of the family of the deceased the sympathy of the Medical Board in their bereavement, and that a copy of these resolutions be transmitted to them and be published in the medical press of the city. (Signed) A. G. Gerster, *Chairman,* Alfred Meyer, N. E. Brill.

Obituary Notes.—Dr. Horace W. Patterson of New York, Chief of the Division of Communicable Diseases of the Department of Health of the Borough of Richmond, a graduate of the College of Physicians and Surgeons, New York, in 1895, a member of the New York State and Richmond County Medical Societies, pathologist to the S. R. Smith Infirmary, New Brighton, and attending physician to St. Vincent's Sanitarium for Tuberculosis, died at the Smith Infirmary, following an operation, on February 6, aged 39 years.

Dr. Emile L. M. Tilly of Kaplan, La., a graduate of the Medical Department of the University of Tennessee, Nashville, in 1886, died at St. Mary's

Hospital, Patterson, La., on December 21, aged 52 years.

Dr. Alexander Hardcastle of Deer Park, Md., a graduate of the Jefferson Medical College, Philadelphia, in 1849, died at his home on January 24, aged 85 years.

Dr. Emory C. Gaffney of Springfield, Ill., a graduate of the Hahnemann Medical College, Chicago, in 1876, died suddenly at his home of cerebral hemorrhage on January 23, aged 61 years.

Dr. Robert P. McKenzie of Rossland, British Columbia, a graduate of McGill University Medical Faculty, Montreal, in 1904, died at his home of penumonia on January 24, aged 34 years.

Dr. James Kerr of Washington, D. C., a graduate of Queen's University, Dublin, Ireland, in 1870, professor of surgery in the Georgetown Medical College, and a member of the Washington Academy of Sciences and of the Medical Association of the District of Columbia, died at his country home in Warrington, Va., on February 2, aged 62 years.

Dr. Louis De Valois Wilder of New York, a graduate of the Geneva Medical College in 1843, for many years attending physician to the Flower Hospital, and a member of the New York Homeopathic Medical Society, died at his home on February 5, aged 92 years.

Dr. George Whitfield Ward of New York, a graduate of the Bellevue Hospital Medical School, New York, in 1874, died at his home on February 8, aged 60 years.

Dr. Robert Hamilton Phelps of Norwich, N. Y., a graduate of the College of Medicine, Syracuse University, in 1894, a member of the American Medical Association, the New York State and Chenango County Medical Societies, the New York and New England Association of Railway Surgeons, and the Syracuse and Binghamton Academies of Medicine, died at his home on February 6, aged 41 years.

Dr. Carl William Rummel of Webster City, Ia., a graduate of the Rush Medical College, Chicago, in 1899; a member of the staff of St. Joseph's Mercy Hospital, surgeon on the Civil Service Board, and a member of the Iowa State and Hamilton County Medical Societies, died at his home of pneumonia on January 31.

Dr. Amy G. B. Kimball of Jackson, Mich., a graduate of the Medical Department of the University of Wooster, Cleveland, in 1877, died at her home of pneumonia on January 29, aged 64 years.

Dr. John F. Byington of Battle Creek, Mich., a graduate of the Department of Medicine and Surgery of the University of Michigan, and a member of the staff of the Battle Creek Sanitarium, died at his home after a short illness on January 27, aged 39 years.

Dr. Augustine von Galny of Galveston, Tex., a graduate of the University of Berlin, Germany, in 1847, died at his home on February 1, aged 84 years.

Dr. A. Monteiro of Richmond, Va., a graduate of the Medical College of Virginia, Richmond, in 1850, and of the Jefferson Medical College, Philadelphia, in 1854, died at his home on January 27, aged 81 years.

Dr. Alfred H. Stickler of Waynesboro, Pa., a graduate of the Bellevue Hospital Medical College in 1866, and a member of the American Medical Association, and the Pennsylvania State and Franklin County Medical Societies, died at his home on January 30, aged 70 years.

Obituary.

EDWARD GAMALIEL JANEWAY, M.D., LL.D.
New York.

Dr. Edward Gamaliel Janeway, one of the best-known physicians of New York, died at his country home in Summit, New Jersey, on February 10. Dr. Janeway was born in Middlesex County, New Jersey, on August 31, 1841. After preparing in the public schools, he entered Rutgers College, graduating in 1860 with the degree of A.B. He then entered the College of Physicians and Surgeons, New York, from which he was graduated in 1864, one year, 1862-63, being spent as an acting medical cadet in the United States Army Hospital at Newark, N. J. Since 1864 Dr. Janeway had practised continuously in New York City, and had held a long series of hospital appointments. At the time of his death he was consulting physician to the Presbyterian, Bellevue, St. Luke's, Mt. Sinai, St. Vincent's, French, and Woman's Hospitals, and the Hospital for Ruptured and Crippled. He had also been largely identified with medical education, having first entered the Bellevue Hospital Medical College as curator in 1868. This office he held until 1873, when he was appointed professor of pathological anatomy, later becoming professor of medicine and Dean of the College. From 1875 to 1882 he also served as Health Commissioner of New York. He was a member of the American Medical Association, the New York Academy of Medicine, the New York Pathological Society, the New York State and County Medical Societies, the American Association of Physicians, and the National Association for the Study and Prevention of Tuberculosis, and was a director of the Russell Sage Institute of Pathology. In 1898, Rutgers, his Alma Mater, conferred on him the degree of LL.D., and the same degree was given to him by Columbia in 1904, and by Princeton in 1908.

Besides holding at various times the presidency of many of the medical societies in which he was interested, Dr. Janeway also found time to serve the public in his professional capacity. As above noted, he was Health Commissioner of New York City for five years; in 1887 he was a member of the Commission of Conference of the Health Department and the Academy of Medicine; during the cholera scare in 1892, he was a member of the Advisory Committee of the Chamber of Commerce and for many years he acted as a member of the Advisory Committee of the Health Department.

Correspondence.

LIGHT FROM ANOTHER ANGLE REGARDING THE ANALYSIS OF THIRTY-TWO THOUSAND CASES OF SCARLET FEVER.

To the Editor of the Medical Record:

Sir:—On page 1053 in the issue of the Medical Record of December 10, 1910, there appears an excellent article, with charts, illustrating the course of scarlet fever for a series of twelve years in Philadelphia, prepared by Dr. Sallom. I write this to call attention to the possibility of influence of the public school on this disease, as illustrated in the charts.

If the reader will turn to the chart, take his pencil and figure a little, remembering that school begins in the middle of September. Notice the number of cases are increased from 135 to 150 by the end of September. The month of October, the first full month of school, the number rises to 200; November is a short month and the number of cases still rises to 245, and would be eight more if we consider 31 days as a month. December embraces holidays, when the children are out of school a week and it does not rise above 250; it should be 300 if it were not for vacation. In January it advances again to 280 cases. February is three days short of 31 days, but if the three days were counted the number would be 275 instead of 245. In March, 270 cases; in April, another short month, 255 cases, but if 31 days are counted it would be 265; in May the cases number 285. The epidemic has reached its height and has been quite uniform in advance since November. In schools being let out in June it drops back to 215. In July, within a month after schools are let out, the number of cases falls to 135 and remain so through August. Turning to the chart on page 1054 of the same issue, at the bottom of the page look at the totals of the number of cases and the mortality and begin to read it in August, when the number of cases totals 1,662, and the number of deaths is 89. Remembering the short months and the school months, it is intensely interesting to me to read the totals, and I wonder what kind of drinking cups or fountains are used in the schools and if they have common books or pencils and monitors that distribute the disease so uniformly during the school months for so many years. Notice the increase per cent. in mortality during the school months.

I have rearranged one of Dr. Sallom's charts on the twelve years' record by cutting it in two and placing it so that it will read from September, the beginning of the school year. This will especially call the reader's attention to the increased mortality during the school years if, as he reads, he will add the correct percentage in the totals to make each month uniformly 31 days. If now, as this table would show, the schools all over the United States cost so many lives of children, our school system is indeed very expensive. It should be remembered that these statistics refer to only one contagious disease.

M. H. Evans, M.D.,

Joplin, Mo.

STERILIZATION OF THE HABITUAL CRIMINAL.

To the Editor of the Medical Record:

Sir:—I have just read with considerable interest Dr. Nammack's article in the Medical Record of February 11, "Is Sterilization of the Habitual Criminal Justifiable?" It has been my opinion for some time that this is a subject which should be approached with a great deal of caution, and it is with great pleasure that I note the conservative stand taken by Dr. Nammack. His views upon the relative importance of heredity and environment coincide entirely with my own. The animistic theories as to the causes of the phenomena of heredity belong to the middle ages and have no scientific basis. The point he makes in regard to the determinate influence of inherited and acquired characteristics is one of importance. Conditions acquired by the individual during intrauterine existence are not inherited states. We have to consider that environment begins its influence with the inception of somatic life. Sterilization of the criminal and unfit is, of course, more easy of accomplishment than the attempt to insure conditions favorable to the proper growth of the developing embryo, or to remove unsuitable environmental influences after birth. But, as Dr. Nammack says, "ethically and morally the proposition is indefensible. Biologically it is foolish."

E. Bosworth McCready, M.D.,
Medical Director, Hospital School for Backward Children.

Pittsburg, Pa.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

SLEEPING SICKNESS—THE WAR AGAINST PHTHISIS—SANATORIUM OR OTHER TREATMENT, HUTS, DISPENSARIES, CARRIERS, ETC.—OSLER'S CAMPAIGN OF HOPE—HEALTH OF THE ARMY—THE BROWN DOG—RATS AND PLAGUE—OBITUARY.

London, Jan. 27, 1911.

The conference on sleeping sickness which, as I reported, was sitting last week at the Foreign Office, has concluded its deliberations. It decided that the route of the new railways ought to be inspected for *glossina palpalis*, that maps of the fly area be prepared, that the lines should cross the fly belt at the narrowest points, no stations, buildings or stopping places being permitted, and that all laborers should be recruited under such conditions as to avoid infection. It is further recommended that during construction a space of 100 yards be cleared on each side of the line and of 1,000 yards on the sides of a river; clearings to be made on the sides of bridges; houses in a fly area to have a clearing of 500 yards. During the working of the railways constant supervision and inspection is recommended and that rolling stock have openings covered with fly-proof gauze, and that as *glossina palpalis* does not probably exist south of the Congo-Zambesi watershed, the Rhodesia-Katanga line be worked in two sections in order to prevent carrying the fly from one area to another.

The twenty-seventh expedition of the Liverpool School of Tropical Medicine, including Professor Todd, Dr. Wolbach, and Mr. E. D. Todd, sailed on Saturday for the West African coast to investigate sleeping sickness in Gambia and Senegal. They were entertained at dinner the previous evening by the president of the school, Mr. W. H. Lever, who, in proposing their health, said that the school had spent nearly £100,000 in research as to tropical diseases during the twelve years of its existence. He believed they had shown the possibility of making the tropics as healthy as other parts of the world, if the problem of the diseases of those parts was scientifically attacked.

In the crusade against consumption there is never any lack of suggestions. I lately mentioned dispensiaries for treatment with tuberculin, and already in five out of the twenty-eight metropolitan boroughs such institutions have been opened. None of these is in the dense population at the East End of London. Dr. F. W. Alexander, medical health officer for Poplar, considering this, has submitted an elaborate report to his council, in which he tells them that early cases are curable by breathing pure air. In London this is hardly possible under present conditions, but, he says, soot, smoke, and dust are only disagreeable, but it is the fetid, close air of crowded sleeping rooms in the small houses of the

poorer class that is fatal. A phthisical man will keep at his work as long as he can, and is sleeping in such a room with his family, who are thus infected. A separate room, or, better still, a porch, would avoid this risk, but is scarcely attainable. Huts at the back of the small houses have been proposed, but the yards are too small. Some have proposed huts in the open spaces, but the idea gets no support. Dr. Alexander suggests that his borough might buy or rent two or more large houses with open spaces in the rear and erect huts in the grounds, the rooms of the houses being also utilized by adaptation of window ventilation and by apparatus for keeping the air charged with ozone. These huts and rooms could be used as sleeping places by persons in the incipient stage attending their work during the day. The saving of life would be enormous, he says, and the saving to the ratepayers proportionate. A man who desired could contribute something for the use of his outdoor hut, and look upon it as his club; recreation and reading rooms could be set apart. Acute cases must not be admitted—nor should advanced ones. An ideal arrangement would be a tuberculin dispensary with a sleeping house attached. The breadwinner would not have to give up work, nor risk the infection of his family, but would be living under the best conditions for arresting his disease. It would be, too, an education in preventive measures, and Dr. Alexander is optimistic enough to think that by such schemes, carried out throughout the country, "tuberculosis would be, without doubt, stamped out."

The enthusiasts for sanatorium treatment are by no means prepared to admit that huts or dispensaries are of equal value, but they cannot deny that the main principle is the same, while the difference in cost cannot be ignored. Both plans are of importance from the educative standpoint. The sanitorium has had a full trial and the many cases discharged as "cured" testify to its value. But, notwithstanding those cures, were all cases picked as suitable for trial, we are beginning to hear of relapses. This suggests that they may have been such as former observers classed as arrested or checked. They were invalids or delicate persons who, from time to time, showed symptoms which our predecessors regarded as ominous of the continued presence of "the tubercle" in the body in a quiescent state, but liable to reassume activity. With our knowledge of the bacillus we may well ask ourselves whether in these cases the organism finds a nidus—whether, in fact, the patients may not be carrying it about—whether there may not be phthisis carriers, just as there are typhoid carriers. Examination of the sputum of "discharged cures" from time to time might be undertaken with advantage.

This subject of "carriers" seems to be assuming greater importance, the idea being that it may be applicable to a more extensive list of diseases. For instance, at Nottingham, where there has been an outbreak of cerebrospinal fever, Dr. Milligan brought before the Medico-Chirurgical Society a paper based on his observation at Belfast Hospital, where he witnessed the epidemic, seeing 300 cases. He said the disease was spread to a great extent by carriers, and that by mild cases, as well as more acute ones. The search for mild cases was, therefore, most important. Lumbar puncture would settle the diagnosis. In this statement he was supported by Dr. Jacob, also by Dr. Atkinson, who had had thirty-three cases in the recent outbreak, with twenty-nine recoveries, all treated by Flexner & Jobling's serum. Three not so treated were fatal. One that had serum and died was one of the earliest. It was stated that Robb's report showed a mortality of 26.6 per cent for cases treated in hospitals by serum, against 85.2 per cent for cases outside hospitals treated without serum.

To return to the educative value of the dispensaries, at one opened last November, Dr. Squire, chairman, and other officials, received visitors on Wednesday and explained the lines on which it has been working. It is open to all, and on a patient's first call full particulars are taken and the treatment prescribed. A nurse then visits the home and arranges for the other members to be examined, so that "susceptibles" are discovered and educated. Some cases may be recommended to a sanatorium. The Public Health Department of the Marylebone Borough, in which this institution is located, is in close touch with the work. The microscopical laboratory occupies the ground floor, the next above being for the examination of the patients. The staff consists of a medical man and a nurse.

The Oxfordshire Association for Prevention of Tuberculosis held its annual meeting in the examination schools, Oxford, on Wednesday. Professor Osler, presiding, said this was a campaign of hope. The lectures that had been delivered and the literature distributed should rouse people to their duty. Within the last fifty years a reduction of mortality from the disease had taken place of about 40 per cent—a wonderful result, largely due to sanitary legislation and the awakening of the people to the prime necessity of health. He thought they might look forward to a further lowering of mortality in their generation, say, 20 per cent more, and that would leave a large percentage for the generation to come. This was certain: if the people would engage in the battle as they should, in 100 years tuberculosis might be as rare as typhus or smallpox is to-day.

The report of Surgeon General Gubbins, director general of the army medical service, issued this week, states that the improved health of the troops, which has been uninterrupted for several years, continued in 1909, in which year there were 570 fewer invalids sent home than in the previous year, although the strength was 5,000 more, and 2,741 less than in 1904. In the four years from that date, ending December, 1908, the improved health of the army permitted the reduction of 2,200 beds at home stations, and further reductions were made in 1909. In the colonies the number was reduced by 901. India, also, shows a well marked all around improvement, admission ratio, death rate, invaliding, and constant sick rates being all considerably lower. The policy of sending convalescents to health stations continues to exert a marked influence, and the hope is expressed that this policy will still further reduce the invaliding figures.

It is to be hoped we may hear no more of the "brown dog." The antivivisectionists have appealed to chancery to compel the Battersea Council to restore their monument to its place. The judge decided there was no contract—moreover, that the words on the base were defamatory and calculated to lead to a breach of the peace. Therefore, if there had been a contract, the court would be going beyond and against its duties to enforce it. So the antis lose their privilege of advertising themselves

and slandering others at the expense of Battersea ratepayers. The proceeding may serve as a warning to other authorities not to accept too lightly the care of effigies which may prove costly. Battersea for a time expended £700 a year in keeping the libelous erection.

Though the sentimentalists have lost the brown dog, another opportunity for weeping is afforded them at Barnes, where there is a large barge industry, and rats swarm in the barges. The medical health officer is sacrificing a couple of hundred of these rats for investigating plague. Think of it—actually 200 of these pretty quadrupeds to be sacrificed to man's desire to abolish plague!

The income of the Hospital Sunday Fund for 1910 was £75,550. The amount collected in places of worship was £40,778, or £1,635 more than in the previous year. The collections at St. Paul's Cathedral amounted to £4,483.

Mr. Joseph Byrne, F.R.C.S.I.,D.L., consulting surgeon to Shiel Hospital and Londonderry County Infirmary, died on January 18, aged 63. He was a magistrate and deputy lieutenant for the county since 1900 and had been for a long time emigration officer and sanitary surveyor for the Board of Trade.

Dr. Samuel Parsons-Smith, J.P., formerly brigadier surgeon, died at Croydon on January 16, aged 68. He was for many years a magistrate for Croydon and chairman of the School Board. He held the volunteer decoration for service in the First V. B. Royal Fusiliers.

Brigade Surgeon Lieutenant Colonel D. Renton, A.M.S, of the Fifteenth Hussars, retired, died on the 23d inst, aged 73.

Fleet Surgeon Rogers, who died at a meeting held to promote a sailors' rest in memory of King Edward, held the Gilbert-Blane gold medal.

Dr. F. Melland, of Manchester, has died at the age of 93, having been connected with many institutions in the course of his long career.

Mr. H. Veasy, F.R.C.S., another nonogenarian, has died after practicing above sixty years, at the age of 92.

Dr. Vivian, surgeon to the Cornwall Volunteers, died on the 13th, in his 90th year.

Dr. Fuller, of Hove, after long practicing in Sussex and taking an active part in public work, has died at the age of 83.

Dr. William Andrew, twice Mayor of Launceston, died there at the age of 61.

OUR LETTER FROM THE PHILIPPINES.

BERIBERI AND POLISHED RICE—606 IN YAWS—JIMSON-WEED POISONING—COMPULSORY MEDICAL ATTENDANCE IN CHILDBIRTH—PERSONAL.

MANILA, P. I., December 15, 1910.

IT is now practically nine months since unpolished rice has been exclusively used at the Culion leper colony as the staple article of diet, and not only has beriberi completely disappeared, after being continuously present for over five years, but no new cases have occurred among the inmates. The sick report shows three cases of beriberi among the inmates during this period, but upon investigation it was found that they were afflicted with the disease at the time of their admission, which was since the use of unpolished rice was begun. In view of the fact that this result was obtained among approximately 2,000 persons and coincides with the experience of Fraser and Stanton in the Straits Settlements and Highet in Siam, it would seem that the time has come when the sanitarian in the Orient at least should take active steps to bring about the general use of unpolished rice where this food furnishes the staple diet. It would appear that this could best be done by legislation along the lines of prohibiting the sale or manufacture of rice that does not contain a sufficiently high percentage of phytin which experience has shown to be necessary to prevent beriberi.

The use of unpolished rice in the Philippines has been attended with many practical difficulties. When the army and the insular government entered the market for the purchase of large quantities of unpolished rice it was found that the rice dealers were unable to supply it because the rice mills were not prepared to furnish it, and they refused to adjust their process of manufacture to meet this new demand. This resulted in large quantities of rice being used which came from the mill immediately after it was husked. The husking machines that are used locally let many of the smaller grains pass through without removing the husks. This rice in the past went directly to the polishing machine, which not only polished the rice, but also removed the husk from those grains which still retained it, so that the finished product was clean. It will be apparent then that the unpolished rice, as it has been used, contained many husks. This gave rise to considerable objection among those who used it. They complained that it tickled their throats and produced gastritis. No reliable evidence as to the latter, however, could be obtained. Prison wardens, commissary officers, and others, who were directly charged with carrying out the orders to use unpolished rice, were constantly beseiged with complaints, and it was but natural that they should take the course of least resistance and recommend that its use be discontinued. To add to the difficulty of those who were insisting upon the use of unpolished rice, the rumor spread that the unpolished rice, when stored in bulk, soon spoiled, thus causing great financial loss. Investigation of this matter showed that there was no reason to believe that the unpolished rice, when stored under the same conditions as polished rice spoiled any quicker.

Analyses made by Dr. Aron, of the Philippine Medical School, showed that the ordinary No. 2 Saigon polished rice, which forms the bulk of that used in the Philippines, contained 0.35 per cent. or less of phosphorus, while the local unpolished rice contains 0.59 per cent. or more of phosphorus. Tests made with chickens showed that a rice containing 0.45 per cent. of phosphorus would not produce polyneuritis and could be regarded as safe for human consumption. A campaign of education was then begun among the managers of rice mills and lately a number of them have produced a slightly polished rice which is clean and yet contains 0.5 per cent or more of phosphorus. Coincidently similar experiments were made under the direction of Highet in Siam, and practically similar results have been obtained. It now having been demonstrated that rice mills can produce a rice that is acceptable in appearance, and at the same time safe for consumption, it would seem that the time has come when suitable legislation can be enacted to prevent the production of any other.

The Manila Medical Society held its regular monthly meeting at the Philippine General Hospital on December 5, 1910, at 8:30 P. M. Dr. R. P.

Strong, director of the Biological Laboratory of the Bureau of Science, read a paper entitled, "The Results of Chemotherapy in the Philippine Islands." This was a report upon a series of cases of syphilis and yaws that have been treated with dioxydiamidoarsenobenzol, or "606." The experience with syphilis was similar to that reported in Berlin, Vienna, and other places where it has been used. The results in the cases of yaws were particularly interesting. A complete cure usually results within a period of approximately ten days. All of the cases were among Filipinos, and the only evidence of the disease that remained was a slightly lighter colored skin at the site of the former yaw lesions. It may be said to act as a true specific in this disease.

Dr. F. W. Bowman, in the absence of Dr. W. E. Musgrave, reported a case of hyoscine poisoning in a Filipino who had ingested a quantity of the fruit of this plant. The plant (jimson weed) grows wild in many places, even in Manila itself, and the datura bean can be gathered at almost any time.

The report of the obstetrical committee, appointed by the society, which was rendered in the form of a proposed law for enactment by the legislature, was rejected by the society as being too rigid for local conditions. It provided that every mother in the City of Manila must be attended during childbirth by a qualified physician. In the discussion which followed, it developed that there were more than thirty births per day in Manila, and these were mostly among the indigent poor, and it was doubtful if enough physicians could be found to render this large amount of free service. The committee was increased in size and the report returned to it for further study.

Major T. C. Lyster, United States army, has been appointed aurist and ophthalmologist to the Philippine General Hospital.

Captain E. D. Kilbourne, United States army, of the army board for the study of tropical diseases, has completed his tour of duty in the Philippines, and sailed for the United States upon the transport which left Manila December 15, 1910.

Reflexes in Surgical Diagnosis.—R. T. Morris notes that specialism has arrived at the point when the neurologist fails to recognize organic causes for surgical symptoms, and when, on the other hand, the surgeon fails to note general conditions which give symptoms simulating those of surgical conditions. The author cites illustrations of cases sent for operation with a diagnosis of ulcer of the stomach which are really cases of gallstones, or bile tract adhesions, or fibroid degeneration of the appendix, or early pregnancy, with symptoms like those of some cases of ulcer of the stomach. Others are cases of eyestrain, or psychoneurosis. Flexions of the uterus often present reflex disturbances. A very small proportion need surgical attention. Some of the cases are dependent upon neurotic spasm. The largest group includes cases of spasmodic flexion in response to a distant peripheral irritation. Many cases of neuralgia belong to the surgical class. Lumbago or sciatica may be due to enlarged prostate, distended seminal vesicles, pelvic adhesions, or septic or mechanical disturbance of the uterus and adnexa.

Disturbances Dependent on Eyestrain.—E. M. Alger states that there are at least three distinct types of fatigue symptom, the muscular, the nervous, and the psychic. First and most common are the symptoms which are purely muscular. The ciliary muscle, for instance, when tired, does not act smoothly, but overcontracts and overrelaxes, so that vision may be at one instant sharp and clear and the next very indistinct. In the same way fatigue of an extrinsic muscle may cause diplopia. This type of fatigue also causes pain localized in the eyes themselves, but both fatigue and pain may be reflected back along the nerves of sensation and cause sleepiness, depression, headache, or neuralgia.

Nasopharyngeal Reflexes.—W. S. Bryant states that more than two hundred and forty-seven different reflexes and reflex neurotic symptoms have been recorded as emanating from some part of the upper air tract, which includes forty-one distinct anatomical structures—the nose with its sixteen parts, the ten parts of the sinuses, the uvula, the velum palati on both sides, the tonsils, both sides of the pharyngeal tonsil, the pharyngeal bursa, the two sides of the fossa of Rosenmüller, two vaults, the two lateral tracts above and below the palate. From any of these parts reflex disturbances may originate. The above-mentioned reflex manifestations are due to at least two causes—local inflammatory or structural conditions. Each stimulation may travel over at least two distinct nerve routes. Multiplying these two hundred and forty-seven symptoms by ten of the anatomical structures (or approximately a quarter of the number of parts), by the two causes, and by two nerve routes—$247 \times 10 \times 2 \times 2$—as a conservative estimate, one finds 9,880 different manifestations from the upper air tract. The reflexes and reflex neurotic symptoms from the nose alone number more than two hundred and twenty, and these effects of a common stimulation act in twenty-four different anatomical groups—the nose itself, the ear, the eye, brain, the head in general, the pharynx, larynx, trachea, esophagus, neck, heart, lungs, parieties of the thorax and abdomen, the stomach, intestines, gall bladder, sexual organs, the genitourinary organs, integument, the muscular and nervous systems in general, the excretory and internal secretory glands, and the circulation. Examples of reflex neuroses of nasopharyngeal origin are paroxysmal sneeze produced by smelling a flower, the cough induced by inhaling fresh air, headache or faceache excited by intranasal pressure, asthmatic paroxysms caused by titillation of the nasopharynx, epileptic seizures induced by intranasal pressure, and cardiac and uterine pains. Simple reflex neuroses can be diagnosed by experimentally inducing a paroxysm. This is done by carefully stimulating every suspected hypersensitive part with a cotton applicator until the active one is discovered and the reflex phenomenon is produced. If this positive method does not determine the diagnosis, a negative one may be employed. Cocainization of hyperesthetic areas during a reflex paroxysm will arrest the attack and establish the diagnosis.

Aural Reflexes.—J. R. Page points out the reflex muscular contractions that occur when the acoustic nerve is irritated by a loud and unexpected sound, and the dizziness, spasm of the respiratory muscles, and changes in the heart action produced by musical tones or by certain kinds of noises. Of more importance clinically are those disturbances caused by irritation of the nerves which supply the auricle and external auditory canal—namely, the neuralgias and coughs due to irritation of the trifacial, and Arnold's branch of the pneumogastric. Every symptom

of seasickness in its most aggravated form can be produced by irritation of a normal labyrinth.

The Meaning of Reflex.—E. D. Fisher states that it would seem apparent that most of the so-called reflex conditions are only referred—that is, the natural conscious perception of a peripheral irritation, whether it be a perception of a color through the medium of the eye, or of hunger through the coating of the stomach. A sneeze can very properly be called reflex and does not call the (cerebral) consciousness into action.

Reflex Symptoms and Disease of the Nervous System.—W. M. Leszynsky states that among the notable medical fallacies none has been more prominent and persistent than that of attributing seemingly obscure nervous manifestations either to some reflex irritation originating in the female genitalia or to so-called imbalance of the ocular muscles. In the majority of instances the causal relationship cannot be satisfactorily established except in the fanciful minds of those with preconceived notions. The disastrous effects of the reflex theory of nervous disease are quite familiar. Yet its misapplication is still more or less prevalent. The unfortunate tendency to ascribe many misunderstood nervous symptoms to so-called reflex causes is due, in a large measure, to the neglect of the majority of physicians to avail themselves of a working knowledge of the fundamental principles of neurology.

Intravenous Use of Cocaine.—P. W. Harrison describes an experiment that he performed upon himself as follows: Into one of the superficial veins of the back of the hand there was slowly introduced five grains of cocaine in a 2 per cent. solution. The introduction of the solution was completed in about thirty minutes. Dizziness and palpitation made it seem wise to stop with this amount. Tests of the patient's condition were made at once and results found to correspond in an incomplete way with those reported for animals. Cerebration was normal except for a restless inability to keep the mind long on one subject. Motor power was quite unimpaired. There was marked analgesia everywhere. An incision ¾ inch long through the skin, well down into the fat, was made on the anterior surface of the lower leg. This incision could be felt. It caused a mere trifle of pain. Two or three small nerves in the fat were cut. Each caused a slight twinge of pain. Apparently operative procedure might readily have been undertaken with only very moderate discomfort. Two hours later a similar incision was made on the opposite side. The sensation of pain had by this time recovered much but not all of its normal intensity. It would seem evident, then, that, however suited to animals this method may be, the relatively enormous dose necessary for even an imperfect result makes it quite impossible for human surgery.

Surgical Treatment of Gonorrheal Epididymitis.—G. G. Smith concludes that, according to the known pathology, epididymotomy is a rational procedure. If care be exercised the danger is slight. The infiltration disappears more quickly than with any other method. The danger of permanent injury is lessened. There is absolute relief of pain. Systemic symptoms are promptly relieved. Medical treatment offers relief, but no permanent cure.

A New Tonsil Knife.—O. H. Lathrop describes a new tonsil dissecting knife that he has devised.

Antiperistalsis in the Intestine.—F. T. Murphy reports a case that adds clinical evidence to the experimental observations that have been made on intestinal antiperistalsis.

To Avoid Mistakes in the Diagnosis of Foot Troubles. M. Strunsky.
Pneumocele of the Lacrymal Sac. E. M. Blake.

Salvarsan.—S. Pollitzer concludes that this drug is by far the most effective symptomatic remedy for the lesions of syphilis. So far as is known at present, the drug may be used without fear of serious injury to the patient in suitable cases, and the dose may be repeated at intervals a number of times. Its employment is indicated in: a. Cases of recent syphilis in which the rapid sterilization of the lesions is a matter of importance for the entourage of the patient and the safety of the community. b. Cases of extensive syphilitic ulceration to shorten the period of local treatment. c. Cases in which important structures, like the eye, the throat, etc., are threatened. d. Cases of syphilitic cachexia. e. Cases with severe lesions in patients who are oversensitive to mercury or are resistant to mercury—the latter are very few in number. f. Cases of syphilis complicated by tuberculosis in which the effect of mercury on the tuberculosis is bad. g. Cases in an early stage of tabes for the relief of pain or of sphincter troubles. h. Cases of hereditary syphilis in infants. In the last two conditions it should be used in small doses only. It should not be used: a. In cases of syphilis complicated with organic disease of the heart or with advanced arteriosclerosis. b. In cases of paresis and advanced tabes. c. In cases with advanced degenerative changes in the brain from any cause. d. In cases with acute febrile disturbances from any cause. e. In confirmed alcoholics. And finally, f, it should not be used for purposes of diagnosis.

Diet in Typhoid Fever.—C. E. Nammack states that the requirements for a suitable diet for typhoid fever cases are three: It should be fluid, it should be easily digested, it should be readily absorbed. For the average patient in the private practice of a general practitioner these requirements must be sought for in foods which are simple, efficient, and cheap. No single article of diet meets the requirements so well as does milk. A close second is found in eggs, when they are fresh and not released from cold storage plants. When milk disagrees, when there is abdominal distention, and when curds appear in the stools, some modification in the administration becomes necessary. In fact, pure milk is never ordered, the author's favorite formula being milk, four ounces; fresh cream, one ounce; lime water, one ounce, given every three hours, and followed by a mixture of dilute hydrochloric acid, ten minutes in one drachm of a reliable essense of pepsin. To this prescription strychnine can be added when required. Between each two portions of milk, albumin water, made by adding the white of two eggs to six ounces of boiled water, is given. The patient is also solicited to drink plain water freely. If there is complete intolerance or aversion to milk, then buttermilk or kumyss or kefir can frequently be borne. After the third week, the author usually allows crackers with butter, well-cooked rice, calves foot jelly, and broth, and other solid foods when the evening temperature reaches normal.

Measurement of Arterial Pressure.—G. Bachmann describes the instrument for this purpose recently devised by Pachon, and named the sphygmometric oscillometer. It is stated that altogether this new instrument has many points which will appeal to the clinician. It is compact, does not necessitate the use of mercury, is devised on sound mechanical principles, is not subject to the disturbing factor of personal equation, permits of easy and rapid readings, and the possibility of the use of a wrist cuff will still further save time and annoyance.

Carbon Dioxide Snow.—E. Pisko states that this substance is not an ordinary cautery, it produces an inflammation, due to the freezing of the tissues; its action and

effect can be fully controlled from a superficial erythema to a total destruction of the diseased tissue. The snow is, as a rule, used in more or less smaller areas and only where a scar as final result is wanted; nevus, hypertrophied scars, angioma, leucoplacia, keratosis, verruca, rodent ulcer, epithelioma, keloid, chloasma, tattoo marks, powder stains, dermatitis, and, last but not least, lupus erythematosus. In all these there is obtained the best cosmetic scar with a comparatively small amount of pain and skin destruction; It is "the" treatment for lupus erythematosus. Anything used heretofore was more or less undesirable for one reason or another, the destruction pertained to the entire skin and not only to the diseased tissue, and the scar would never be controlled; here one gets the best cosmetic results, and furthermore, with a few applications one can prevent the process from spreading, quite a factor for the face of a female. In conclusion, the author states that the reliable and inexpensive snow fully takes the place of the high-priced radium, but never the surgeon's knife when glandular involvement is present.

Syringe for Local Anesthesia in Rectal Surgery.—J. F. Saphir states that he has devised a syringe which has proved very satisfactory for infiltration of the tissues to produce local anesthesia in operations about the anus and rectum. The advantages possessed by this instrument are: The syringe is all metal; it is perfectly air-tight; it can be easily taken apart and just as easily put together again; it is very easily sterilized; it is always in order; it can be used with the ordinary hypodermic needle; it has revolving finger rings to enable one to get a better grip on the instrument, no matter in what position the instrument may be at the time of insertion; it has a permanent knee or shoulder attachment to enable one to get a better and unobstructed view of the field of operation while injecting the local anesthetic into the tissues; it does away with washers of all kinds, with the exception of a small washer between the needle and the instrument proper.

Creosote Inhalations in Pneumonia.—B. Robinson states that one of the most important things to be constantly borne in mind in the prophylaxis and treatment of pneumonia is the proper and efficient use of beechwood creosote by means of inhalation. There is nothing so simple, effective, or harmless in the prophylactic and curative treatment of croupous pneumonia and also catarrhal pneumonia as inhalations of warm creosote vapors from the ordinary croup kettle filled with water and allowed to simmer over a lamp burner or stove, in a more or less continuous manner during the inception and continuance of pneumonia. Further, the author ventures to affirm, no nurse or attendant will take it from the patient thus treated.

Diagnosis of Foot Troubles.—M. Strunsky states that flat foot or weak foot are often concomitants or symptoms of serious local or constitutional diseases. At present there is a tendency to attribute the patient's complaint solely to the depressed arches, the reason being that the changes in the arches are often glaring, while the constitutional cause, which may be perhaps the prime factor of the entire trouble, is intrinsic and requires a repeated and careful examination in the incipient stage to detect it. In examining foot cases the physician should look for a constitutional cause if he is to avoid the risk of calling incipient arteritis obliterans, locomotor ataxia, chronic gonorrheal foot, and a host of other troubles, flat foot or weak foot. Special stress is laid on the values of examining the arteries of the foot as a routine in every case of foot troubles, for the patient is sure to attribute the unfortunate termination of arteritis obliterans to the physician's treatment.

Pneumocele of the Lacrymal Sac.—E. M. Blake reports a case of this condition, and notes that, if one can judge from the literature of lacrymal sac affections, the condition of pneumocele is very rare. Or it may be that a more careful lookout for the anomaly would show it to be commoner than we think. Considering the relative frequency of disease of all portions of the lacrymal apparatus, it would seem that we might oftener have the anatomical requisites for the entrance of air from the nose into the sac with no avenue of egress above, producing a pneumocele.

Cancer of the Breast.—By M. H. Richardson. See MEDICAL RECORD, Vol. 77, page 1109.

Disturbances of Lactation.—A. C. Cotton states that no secretory nerves have yet been observed in the mammary glands, but we are compelled to accept the hypothesis of nerve influence and control of the secretion of milk, probably through the cranial and sympathetic nerves. The milk supply seems to be regulated by the demand, to a certain extent, in some mysterious way. It is believed that the surplus, if not drawn, is reabsorbed. It is accepted also that the constituents of milk may be influenced by mental and other conditions, and disturbances of digestion in the infant are frequently the first evidences of its disturbances. Pregnancy has long been regarded by the majority of observers as a contraindication to suckling, but the opinions differ widely as to the effect of the return of menstruation and of coitus. The author has looked up the literature as regards these matters extensively, especially the latter. He finds a wide range of opinion, some authorities considering coition during lactation harmless to the mother and child, and others condemning it. He believes the early reappearance of menstruation can be caused by coitus. His observations lead him to the conclusion that pregnancy, menstruation, and copulation, in the majority of cases, have an unfavorable effect on lactation, and the apparent exceptions only prove the rule. As a result of these misplaced reproductive functions, he has noted the injurious effects on the nursling in varying degrees, from retarded growth, loss of weight, athrepsia, marasmus, and acute gastrointestinal disturbances, to sudden death and convulsions or coma from acute intoxication. He says the gynecologist has demonstrated that cohabitation has in many instances been incompatible with successful treatment, and has therefore learned to control the sexual relations. He asks whether it would be any more difficult for the pediatrician to do the same.

Complemental Feeding.—T. S. Southworth advocates supplementing the more or less deficient secretion of mother's milk instead of abandoning the latter entirely, as is too often done. Much that has been accepted as to the occurrence of poor or injurious breast milk must be given up in the light of later researches. One must recognize the fact that mucoid and somewhat frequent stools, ranging in color from dark green to golden brown, and containing but little fecal residue of milk, are the stools of relative starvation and not of digestive disturbance caused

by abnormal mother's milk. The breasts function poorly often because of defective nutrition of the mother, and her nutrition should be attended to and the natural breast milk should be utilized as much as possible in the important early weeks of life. After the first postnatal loss of weight the infant's growth should be progressive, and when this does not happen, or, having happened, ceases, experience teaches that the matter is more serious than mere stationary weight. There may be loss of assimilative power. If, after waiting ten days or two weeks, attention being given to the diet and nutrition of the mother, the breast milk is still insufficient, small supplemental feedings are advisable instead of discarding the breast milk altogether. It is better, the author thinks, to give small bottle feedings each time the baby finishes nursing. For these he prefers the term "complemental feedings" as distinguished from the supplemental feedings, given occasionally to nursing infants, instead of the breast. These complemental feedings must first furnish food in simple and assimilable form, not disturbing digestion, and they shall be so small in quantity as not to exceed, together with the previous nursing, the normal capacity of the stomach of the infant at this age. One-half ounce at first and later one ounce are usually sufficient for a recently born infant. This increase may be made when the age and growth of the child indicate a larger stomach capacity, or earlier if the residue in the stools or the weight of the infant before and after nursing show a larger deficiency of breast milk. The materials used have been barley water, whey, or one of the proprietary combinations of maltose, dextrose, and dry condensed milk; of the latter a fairly level teaspoonful is used to a half ounce of boiled water. Barley water has small food value and cannot be used alone for long at a time, but it is an aid to the proper digestion of over-rich breast milks and an excellent medium for the addition of cow's milk. If the subsequent progress of the case shows that, with further failure of the breast milk, more food is needed, an infant so fed makes the transition to bottle feeding very easy. Whey and the maltose-dextrose-milk combinations have proved useful in the author's hands, and may be continued for considerable periods if the breast milk holds its own. If it increases they may often be discontinued, but if the nursing gradually fails they should be replaced by suitably modified fresh cow's milk, since neither is suitable to maintain well-rounded development when given exclusively. Artificial feeding of the very young child requires close supervision, and this, for many reasons, is not possible in most cases. The safer progress of the infant receiving breast milk needs no argument.

Fats in Infant Feeding.—C. Douglas condemns the use of high-percentage fat feeding to infants, which can stand more of this substance soon after birth than they can a little later. It is a serious mistake to increase the proportion of fats in foods for its laxative effect, and, while it is important that each infant should receive the highest percentage of fat that it can digest, it is equally important that we should recognize the first symptoms of fat indigestion. There is no food that will so completely check the growth and development of an infant when it is imperfectly digested. It requires less than 0.5 per cent. of imperfectly digested fat to prevent a child's growing, disturb its sleep, destroy its color, and pave the way for further malnutrition. When a child cannot digest fat it takes some trouble to select a suitable carbohydrate. Oatmeal will not do and, while barley fat is less hurtful than oatmeal fat, many infants cannot take it. His experience is that infants with feeble fat digestion get along better when fed rice starch than they do with any other. It contains less than 0.5 per cent. of fat, a low percentage of protein, but a high and easily digested proportion of starch. The most suitable proteins are found in nitrogenous foods, skim milk, white of egg, and meat juice.

Yersin-Roux Serum in Plague.—A. N. Sinclair reports three cases of plague, in a father and two daughters, treated by the Yersin-Roux serum. One of these was fatal, a pulmonary case. Here the serum failed. The second case, that of the father, was of the bubonic type and was cured by two injections. The third was similar but milder, in the younger daughter, aged 8. The injection was given earlier than in the other two cases, and a single one was sufficient. The first patient had been ill four or five days before treatment, the second over two days, and the third only 36 hours. The serum used was that known as "dry serum," and was made by the Pasteur Institute. Sinclair thinks that is far superior to the liquid serum, which he believes is perhaps responsible for the poor results reported by some observers.

Trifacial Neuralgia.—V. P. Blair reports the results of treatment by deep injection in twenty cases of true tic, all showing similar clinical features, the neuralgia being confined to the distribution of one or more branches of the fifth nerve. This, judging from the anesthesia caused by the injections, seems to vary a little in different cases, in one or two the anesthesia crossing the medium line or extending behind the ear. The pain was always paroxysmal and sometimes irregularly periodic, always in the same place and usually confined to one side. The trunks and branches of the affected nerves were not, as a rule, tender, but there were almost always special points, irritation of which would cause twinges in the pain spot. The patients acquired a certain habituation to pain in the older cases, though it was always severe. Contrary to the author's previous ideas that trifacial neuralgia was a disease of later life, in these cases it occurred in all decades from the second on. All previous treatments, except removal of that part of the Gasserian ganglion from which the affected branches sprang, had been but temporarily effectual. Removal of the apparent cause only temporarily controlled the pain. The causes varied. Fifteen of the twenty patients were subjected to deep injections of alcohol, and with other anodynes with alcohol as a basis, though slightly varying otherwise. The method of finding the proper place to inject, etc., and the results obtained are given in detail. The latter seem to warrant the conclusion that the more definitely a paroxysmal pain has been confined to certain spots, especially on the second and third division, the greater becomes the relief from deep injections. The procedure, he thinks, cannot be absolutely free from danger, but it is probably safer than a Gasserian ganglion operation.

Tuberculosis in Pennsylvania.—J. B. Deacon notes that $2,000,000 was appropriated to be used by the State Department of Health for two years' tuberculosis work, as against $1,000,000 in 1907. In no other State has such an immense sum been set aside for the purpose. Deacon reviews the legislation in other States, and gives a statement of the needs of the work at present in Pennsylvania. The most pressing need is for the care of advanced cases, which form the greatest menace. This, however, is essentially a local problem, and the policy seems to be in Pennsylvania to have the State care only for early cases.

Edema After Salvarsan.—R. L. Sutton observed in two of his cases a peculiar subcutaneous swelling, which he has not seen elsewhere described, appearing in the lumbar region 48 hours after the injection. In both the tumor was oval in outline, 4 by 10 cm. in dimensions, its long axis being parallel with that of the spine and its lower border on a level with the top of the sacrum. They projected 2 cm. above the general level, appeared suddenly and were painful and very tender to the touch. At no time could fluctuation be obtained. They disappeared in the course of five or six days, leaving no trace. There was no connection between the needle puncture and the

swelling; in each instance they were about 30 cm. apart. He is at a loss to account for their appearance unless one considers them lesions of urticaria gigans, but he thinks that they are suggestive of the results that sometimes follow the sudden liberation of large amounts of treponema endotoxins.

Needles in the Tissues.—E. P. Quain notes the difficulties of removing broken needles in the tissues, and describes his method of removing them as follows: A local anesthetic should be injected and an incision made some little distance from the point where the needle entered, and on that side toward which the needle traveled when entering. The distance may be one-half inch or more, depending on the depth and slant of the needle. The incision should be made so as to strike the long axis of the needle in a plane approaching as nearly as possible a right angle. The knife will thus cut down on the side of the needle. The needle is readily made out and grasped by means of a small forceps. It is often impossible to extract the needle through this right-angled incision without danger of anatomic injury, or of breaking the needle. The needle should then be held firmly by the forceps while another small incision is made through the skin at the point where the needle entered. It will be found an easy matter to push the needle out through this opening by means of the forceps.

Colophonium in Strains.—S. B. Wolbach, noticing the difficulty of obtaining constant results in cell differentation with the eosin-methylene-blue method, reports the results of experiments with the addition of colophonium in varying amounts. This furnished a certain method of obtaining any desired effect obtainable by the eosin-methylene-blue method. It also made this method applicable to tissues fixed with formaldehyde solution and alcohol, and permitted the use of commercial grades of methyl alcohol and methylated spirits in place of the more costly 95 per cent. ethyl alcohol.

Improved Tonsil Knife.—G. L. King has devised for the purpose of quickly and more easily enucleating tonsils a knife of small size with both angles sharp. Its small size assists very greatly in its manipulation within the mouth. It can be used with dispatch for dissecting in almost any direction.

Ventricular Puncture in Meningitis.—S. R. Benedict reports a case of cerebrospinal meningitis in which he aspirated one and a half ounces of cloudy-cerebral fluid from the right cerebral ventricle and injected 20 c.c. of antimeningitis serum, closing the wound without drainage. Marked temporary improvement followed. Four days later, however, the patient became markedly worse and died with a temperature of 104.6 F. Necropsy, performed one hour after death, showed almost normal conditions in the right ventricle. In the other, however, the disease was apparently unaffected. In another similar case, he says, he will not overlook the other ventricle.

Refractive Error Simulating Brain Tumor.—T. Diller reports the case of a patient who had suffered in four railroad accidents, in one of which the left side of his head was severely injured. When first seen, the patient had suffered for three months with attacks of headache and dizziness of increasing frequency and severity. The headaches were chiefly occipital, though occasionally frontal, and there was a good deal of pain in the temples. Other symptoms were vomiting, double vision, and gradual loss of sight. Reference of the patient to an oculist showed perfectly normal eye-grounds, but a strong refractive error, on the correction of which, by glasses, all the symptoms disappeared. The refractive error seems to have been responsible for the symptoms warranting a diagnosis of brain tumor.

Precautions in the Use of Salvarsan.—J. F. Schamberg and N. Ginsburg state that the most recent advice from authoritative sources, as well as their own experience, favors, in general, the employment of salvarsan by intravenous injection. Salvarsan should not be used in myocarditis, in advanced cases of tabes dorsalis and general paresis, in nerve syphilis affecting vital centers, in grave kidney disease, in cachectic and debilitated persons (unless the condition is due to syphilis), in aneurysm, in optic neuritis, and in persons with lesions (such as gastric ulcer), in whom increased blood-pressure may produce hemorrhage.

The Hospital Unit in University Work.—W. Osler states that out of the laboratories, as the result of work done by men absorbed in study and usually without the slightest bearing upon practical problems, came the three great revolutions of the nineteenth century—the annihilation of time, the substitution of the machine for the hand, and the conquest of disease. The study of the art of treating disease is one of the important concerns of the university. For this purpose the latter must be allied with the hospital. The author then discourses on what a hospital stands for in the community. Primarily for the cure of the sick and the relief of suffering; secondly, for the study of the problems of disease, and, thirdly, for the training of men and of women to serve the public as doctors and nurses. A majority of hospitals deal only with the first of these objects, and incidentally with the third. All agree that a study of the problems of disease and the training of men and women in the technique of the art come within the sphere of the university. In a medical faculty with 300 students, for which the necessary hospital accommodation would be about 500 or 600 beds, a unit would represent a clinic in the continental sense, of which there would be five or six major, and as many minor—the former including medicine, surgery, midwifery and gynecology, psychiatry and neurology, pediatrics and opthalmology; the latter, dermatology, dentistry, laryngology, otology, syphilis, and genitourinary diseases. There might be, as in Berlin and Vienna, two or three medical and the same number of surgical units. The professor has three duties—to see that the patients are well treated, to investigate disease, and to teach students and nurses. He should be a man of wide sympathies and of trinocular vision. He should have a comprehensive and thoroughly scientific training, and should enter clinical medicine through one of three portals—physiology, chemistry, or bacteriology and pathology. He must be keenly practical, keenly scientific, fond of his patients, fond of his work, and devoted to his students. He should live as much in his wards and laboratories as do his colleagues in their laboratories of anatomy, physiology, chemistry, or physics. In a hospital to which many acute cases are admitted a male and a female ward with about thirty beds each, and with a few small extra rooms, would furnish ample clinical work for a senior class. In every way it is a convenience to have the laboratory rooms in close proximity to the wards, and when feasible they should form an essential part of the unit, but for the sake of economy they may be merged, and all the pathological work concentrated in one building. Nowadays provision should be made for (1) cardiorespiratory physics and physiology; (2) bac-

teriology and vaccine therapy; (3) chemistry; (4) microscopy; (5) *x*-ray and electrical work, and (6) a general laboratory for the students. As regards the organization of the staff, there should be four groups. First, the senior assistants nominated by the professor, holding university as well as hospital appointments, and who should be prepared to remain for an indefinite number of years. In a clinic of moderate size three such could be utilized. The first assistant, a man of some maturity, should be in full charge of the departments in the absence of the professor. The position should be made attractive and ample opportunities should be given for original work and for teaching. From this group the medical faculties throughout the country would be recruited. Secondly, the junior assistants, house physicians, appointed annually and by competition from the members of the senior class. Thirdly, laboratory chiefs, who need not be resident; but it is a good plan to have one of the senior assistants in charge of the laboratories, and one who is at the same time responsible for the laboratory teaching of the students. The arrangements vary greatly at different clinics, in accordance with the leanings of the professor towards chemistry, physiology, and physics, or bacteriology. Fourthly, an out-patient staff made up of assistant professors in the department, as a rule men in private practice, and who are in charge of the junior teaching. Entering one of the clinical units, a student should be made to feel a part of it, having his share in caring for the patients and in studying the disease, and even in the teaching. He should be made to feel that the hospital is his home. This has been one of the special boons enjoyed by the British medical student in his senior years; the hospital has been in reality the medical school, and there has not been that dissociation between the two which exists too frequently elsewhere. The teaching should be entirely practical.

Auscultation of Joints.—A. E. Garrod states that it is a familiar fact that noises are produced in joints, for such sounds are in some instances so loud as to be clearly audible to bystanders, and far more often attract the notice of the persons in whose joints they are produced. The loudest articular sounds are those which have little or no morbid significance, and, speaking generally, the most noisy joints are seldom those which are the seats of the more serious forms of disease. Apart from the more conspicuous reports and crackles above referred to, there are abnormal articular sounds, of much fainter character, which are only audible with the stethoscope, and, from experience gained from systematic examinations extending over some years, the author has become convinced that auscultation affords valuable aid in the diagnosis of the several forms of morbid change to which the joints are liable. To sum up, it may be claimed for auscultation of joints that this method is capable of affording early warning of troubles in articular structures and sometimes reveals the commencement of disease in joints which to inspection and palpation appear to be normal, and which may even cause no discomfort to their possessor. Again, the method gives promise of help in the differentiation of articular diseases, and in distinguishing between those in which the cartilages and bones are implicated, and those in which the synovial membranes and soft parts around the joints alone suffer. If these claims be justified, auscultation of joints does not merely supply information which can be equally well obtained in other ways, but promises to lead to the extension of our clinical knowledge of the conditions in which it is employed.

Transperitoneal Cystotomy.—S. Pringle states that the disadvantages of the suprapubic route for tumors of the bladder are as follows: It is difficult to obtain a proper view of the growth. The hemorrhage is difficult to control and further obscures the view. In the cases of malignant growths it is almost impossible to define their limits, and if the orifice of either ureter is involved, as it frequently is, the very greatest trouble is found in dealing satisfactorily with the severed ureter. There is also the danger of infecting the prevesical space. The results also of the suprapubic operations have been most disappointing. The operation of intra- or transperitoneal cystotomy obviates all the difficulties of technique which are enumerated above. At the same time it lessens the immediate mortality, and will certainly improve the end-results, as it enables one to deal much more radically with the growth.

Puerperal Eclampsia.—W. Alexander states that there is no disease where the results of treatment are so unsatisfactory and so uncertain as in puerperal eclampsia, and in few diseases are there so many, so varied, or such opposite methods of treatment. This arises from the imperfect knowledge of the disease that we possess and from the apparent facility with which serious cases rapidly improve, or the rapidity with which apparently favorable cases become worse or unexpectedly prove fatal. Hence the undue advocacy of remedies which have been followed by recovery in apparently hopeless cases by some medical men, and the low opinion of the efficacy of the same remedies by other medical men who have used them in apparently favorable cases that, nevertheless, turned out unsuccessfully. The author reviews thirty-eight cases of eclampsia that had been treated at the Liverpool Workhouse Hospital.

Rôle of Autoinoculation in Medicine.—C. Riviere states that his thesis readily divides itself into two arguments, which may be briefly stated as follows: First, that a form of vaccine therapy has long been applied, unconsciously but successfully, by physicians in their treatment of infective processes in the body. Second, that the success attending this practice might be increased if it were developed into a conscious aim under the guidance of recent knowledge of the subject of treatment by vaccines. One has thus two natural processes to study and imitate: 1. "Irrigation" of the infected area with plasma and leucocytes, and this by itself may be enough to cure a mild invasion. 2. Autoinoculation, or the washing of the bacterial products into the blood stream to stimulate in the tissues the formation of antibodies specific to the invading micro-organism. These are the processes (other than the injection of vaccines) which the physician can direct with success, and it is this "natural vaccinetherapy" that was exploited with success in the time-honored practice of applying heat (poultices, etc.) to an inflamed area. By this means not only was irrigation assisted, but such irrigation, itself of value, necessarily led to an increase of that autoinoculation on which the improved resistance of the body depends. Such an effect is obvious so far as the poultice is concerned, but it is not so obvious, and, the author points out, how also the drug treatment of infective diseases may have depended for its success, so far as it has been successful, on a similar encouragement of these processes of "irrigation" and "autoinoculation."

Cerebral Tumor Affecting Corpus Callosum.—R. T. Williamson describes a case, the chief clinical features of which were the following: 1. The fine tremor of the lips, tongue, facial muscles, and of the hands and arms; the tremulous speech and mental impairment; symptoms suggesting general paralysis. 2. The absence of headache and vomiting until the termination of the disease (last two weeks of life). 3. The marked double optic neuritis. 4. The well-marked Babinski and Oppenheim reflexes on both sides, without ankle clonus or definite paresis of the limbs. The presence of the well-marked Babinski and Oppenheim reflexes on both sides suggested a median intracranial lesion, and did rouse at one time the suspicion of tumor of the corpus callosum; but it was not felt that this localization could be made with certainty from the symptoms. The author thinks it probable that in cases of intra-

cranial tumor the presence of bilateral Babinski or Oppenheim reflexes, without ankle clonus or paresis of the limbs, will be found to be a useful indication of a median position of the tumor growth.

Subluxation of the Knee.—I. J. W. Evans states that the conservative treatment of this injury consists in fixation of the joint in the extended position for a period of about six weeks after replacing the cartilage; this is followed by application of an apparatus.

Atonic Dilatation of the Stomach.—P. A. Mitchell describes a new method of treatment that he has devised for this condition. The point on which the whole treatment turns is the discovery of a series of superficial skin areas, the gentle stimulation of which causes contraction of the distended stomach, the opening of the pylorus, and consequent emptying of the contents into the duodenum. It is a pure reflex action. The areas lie along the margin of the ribs, commencing at the tip of the tenth costal cartilage on the left side, ascending to the tip of the sternum and down the costal margin on the right side. The manipulation is carried out as follows: With the patient flat on his back, place the phonendoscope on the right of the umbilicus and seat yourself on his right side facing his head. Place your right hand on the patient's abdomen, with the tips of the fingers at the costal margin, find the tip of the tenth rib, and with the tips of the first, second, and third fingers very gently glide, with a trembling motion, over the skin. A hard tap produces a spasm of the pylorus, and all attempts to empty the stomach are futile for some time. It is the delicate, light touch which is efficacious. After a few seconds or minutes (it varies), action will be heard beginning in the stomach. The first to leave is always gas; consequently "pistol-shot" or "explosion sounds," according to the quantity escaping at one time, will be heard. Cease the stimulation until that contraction has stopped, then proceed again in the same manner, and all the gas will thus be driven out. Then quite different sounds can be heard; a low, muttering, crunching sound begins; it increases in intensity as it approaches the pylorus, and, this opening, a sizzling or rushing sound of fluid is heard. These waves succeed one another until the stomach is quite empty, and when there is nothing more left the soft blowing, sighing sound can be heard as wave after wave travels across the empty stomach.

The Pitfalls of "Mental Tests." C. S. Myers.

Yellow Fever in West Africa.—Sir Rubert Boyce presents a review of the history of yellow fever in West Africa, which shows that yellow fever is far more prevalent than is usually supposed. In fact, his observations prove, in his opinion, that yellow fever is endemic to-day amongst the natives of the coast towns, precisely as it was amongst the Creoles, the yellowskins of Havana, Rio, Santos, Para, Vera Cruz, etc. If the mining managers and merchants will forearm themselves by adopting the rational precautions of segregation and Stegomyia destruction on the West Coast they need not fear the awful setbacks to commercial progress which the towns above named experienced from yellow fever.

Puerperal Eclampsia and Venom Poisoning.—H. L. Murray states that, as seen in the liver, the lesions of eclampsia consist of three definite and distinct changes. First, and without exception, there is a degenerative change widespread throughout the gland, and varying in intensity in different cases. This degeneration is usually rather more marked towards the center of the lobule, and may in that region proceed to a little irregular necrosis. Secondly, and very commonly, although by no means invariably, there is seen towards the surface of the liver a very peculiar condition of focal necrosis in the periphery of the lobule. This necrosis is strictly limited to the outer zone or to part of it, and does not gradually merge into the degeneration seen in the middle and inner zones. And, thirdly, there is frequently seen, particularly towards the surface of the organ, a certain amount of blood extravasation, especially in association with the necrosed areas. There are four constituents of the eclamptic toxin—a hemolytic, a neurotoxic, a hemagglutinative, and an endotheliolytic. Of these only the first two can be demonstrated to be constantly present, although the third may also be there, but masked. Death may ensue without marked extravasation of blood—endothelioysis—although it cannot be doubted that a serious hemorrhage into a vital part of the brain sometimes determines a fatal result where the hemolytic or agglutinative lesions do not appear inconsistent with the continuance of life. In venom poisoning all four principles of the eclamptic toxin are found, but in very varying degree. In the cobra the results are mainly hemolytic and neurotoxic; in crotalus, mainly endotheliolytic, with relatively little hemolysis and agglutination; in *Daboia russellii*, almost purely hemagglutinative. There is, then, very considerable evidence that the pregnant woman is protecting herself against a poison directly comparable to a venom, and on this ground the author suggests that there may be some therapeutic use for antivenin in eclampsia or the pre-eclamptic state. Judging from its action in snake poisoning, the likelihood of usefulness is very much greater in the latter. Antivenin is as harmless as any other antitoxic serum, and may, and indeed should in eclampsia, be given in large quantity by intravenous injection. There is, of course, no reason for omitting any other therapeutic measure which may be considered advisable. There is still one further suggestion which he makes. The convulsions of eclampsia are in no way an essential of the toxemia. Patients occasionally die quietly in coma with lesions identical with those found in cases of convulsive seizure. Arrest of the convulsions, therefore, is not necessarily antidotal, but has the merit of saving the patient's strength. It should be accomplished, then, in a way as little harmful to the patient as possible. It follows that anesthetics, which are powerful cell poisons, are bad. The other two standbys in this regard are veratrum viride and morphine.

Scopolamine-Morphine Anesthesia in Labor.—J. R. Freeland and B. H. H. Solomons draw the following conclusions from the study of 100 cases: Scopolamine need not be given in larger doses than 1/120 grain; in the majority of cases it may be given advantageously by the mouth; it is undesirable to keep patients in a darkened room whilst under its influence; the patient should be carefully watched. This can be done equally well by the nurse as by the doctor; no ill effects to mother or child need be expected to follow the rational administration of scopolamine; whilst its chief indication will be found during the first stage of labor, the fear of rapid delivery following its use is not a contraindication.

Cesarean Section for Dystocia.—A. Routh states that where ventrofixation causes dystocia, living children can be delivered with small risk to the mother by Cesarean section, which may be safely done after other attempts at delivery have beeen made, provided that antiseptic precautions had been carefully adopted.

Absence of Fallopian Tubes and of Menstruation.—

W. G. Spencer reports a case of this condition, in which there were monthly recurrent attacks of peritonitis. The condition was relieved by an operation, which joined the ovarian pouches with the uterine cavity.

Prolapse of Inverted Uterus.—A. S. Hendrie reports a case of inversion and prolapse of the uterus during labor. Prompt removal of the placenta greatly facilitated reposition of the uterus.

Treatment of Rectal Cancer.—H. Cripps states that the particular route by which rectal cancer is removed is a matter of quite secondary importance. The really important point in rectal cancer is whether it can be removed with advantage to the patient. Surgeons differ very much as to what they consider the class of case suitable for removal. Those which the author considers suitable are cases in which the growth is still confined to the rectum, and does not extend beyond it. In very many cases one can ascertain whether it is confined to the rectum by noting its degree of fixity. If he feels disease in the bowel, and is able, with the finger, to push it up or down or rock it from side to side, he is sure it can be removed with advantage to the patient. But if the examining finger passes into a narrow part of the rectum and the disease extends round it, and he is unable to move the diseased part without at the same time moving the patient bodily, he generally finds it useless to attempt removal. In this disease it is well to err on the side of doing too much rather than too little. Inasmuch as a number of these cases are curable if operated upon early, it is a pity that practitioners do not spend more time in the study of the symptoms of rectal cancer, for they are obvious. Nevertheless, time after time cases present themselves which have been treated for long periods as chronic dysentery, intestinal catarrh, piles, etc., without any examination having been made, whereas if that simple precaution had been taken the nature of the disease would have been early apparent, and they might have been treated by operation with permanent success instead of having drifted into a hopeless condition.

Vaccines in Rheumatoid Arthritis.—G. A. Bannatyne and J. Lindsay state that they have for some time past made systematic examination of the blood in cases of acute rheumatoid arthritis, and in certain cases microorganisms have been isolated and vaccines prepared. They present the history of two such cases, and the results have been so exceedingly satisfactory that they are encouraged to hope that in vaccines a cure may be found for many acute cases of rheumatoid arthritis. In both cases the microorganisms were obtained from blood taken from the veins of the antecubital fossa of the arm, after every precaution had been taken to ensure the impossibility of skin contamination. The medium on which the cultures were obtained was blood agar, and during the period of growth the incubator registered 35° C. In the second case reported, after there had been no improvement in the condition of the patient, a culture was obtained from the patient's own blood, and a vaccine prepared. Injections of 5,000,000 were given on alternate days. There was no rise in temperature after any of the eleven injections given. Immediately following on the administration of the second dose the patient lost practically all her joint pain. After three or four doses she was able to move her joints more freely than she had been since the onset of the condition. She improved steadily and continuously till she left the hospital.

Proposed Coroner's Bill.—J. Griffiths presents an outline of a scheme of legislation for a simple and economical organization of the coroner's office.

The Pitfalls of Mental Tests.—C. S. Myers notes that psychology seems likely to suffer from the same dangers of popularization as have for years past been affecting anthropology. Just as it has been widely supposed that only a printed book of instructions and queries need be read for an amateur to sally forth into the field and collect reliable physical measurements, or trustworthy evidence of social organization, so there appears to be starting a belief that no special course of training is necessary in order to conduct on a large scale investigations of a psychological nature. The plain man believes that "one can prove anything by statistics," and such time-worn sayings have a certain basis of truth. For the wholesale collectors of measurements are apt to pay too little regard to the complexity of the conditions influencing the problem and the material which they are gathering. All they desire is an enormous mass of data, and these—good, bad, comparable, and non-comparable—they pour into the statistical mill with the object and result of arriving at conclusions statistically invulnerable. For these reasons the author urges extreme caution, at least for the present, in standardizing "mental tests" and in popularizing their use.

Berliner klinische Wochenschrift.

January 23, 1911.

Treatment of Lupus of the Nasal Cavity by Pfannenstiel's Method.—The Pfannenstiel referred to is a Scandinavian physician, not the recently deceased German surgeon. His method was first described in 1910, in reference to intranasal tuberculosis ulcers, which seem to have been lupus, technically, at least. The method consisted in the exhibition of iodide of potassium per os, with synchronous introduction of ozone in the nasal chambers. The theory was as follows: If KI is given inwardly it is partly eliminated by the nasal mucosa, the iodine being at the same time set free. The nascent iodine is known as a powerful bactericide, and the introduction of ozone in the form of hydrogen peroxid is shown to be a strong synergist (H_2O_2 without the KI was shown to be inert). The combination of the two substances liberates the iodine and also sodium hydrate. Besides hydrogen peroxid other substances containing ozone were used. The so-called oxydol of Petri, perhaps a proprietary, was ultimately chosen on account of its greater stability and was introduced in tampons. It is stated to be a "3 per cent. solution of H_2O_2 freed from acid." The present writer, Strandberg, of the staff of Finsen's Light Institute, Copenhagen, reports in all 13 cases treated by this method. A study of these appears to show that they were all examples of lupus vulgaris of the internal and external nose and adjacent cheeks. They caused in time very destructive ulceration within the nose. No bacteriological reports are given. The actual determination of the tuberculous nature of the disease seems to have been afforded by a positive Pirquet reaction. Suspicious cases tested with Wassermann reaction for syphilis gave a negative result. Curettings in some cases gave the paratuberculous structure, which, of course, is also present in actual tuberculosis. The patients seem to have been well as a rule and to have shown no other evidences of tubercle. Hence, we must conclude that what the Danish author calls a lupus vulgaris largely limited to the nose is a true lupus and not a tuberculosis of the nose in the ordinary sense of the word. That the bacteriology is not even mentioned confirms this opinion, for lupus is so free from bacilli and pursues such a prolonged, often life-long, course that it is often regarded as a paratuberculosis. The results obtained by the treatment were not only strikingly good but some cases yielded in a few days or weeks. The greater the duration, the longer the treatment, and, of course, the deformity persists. A special case is given in which an apparent lupus gave a positive Wassermann reaction, leaving a little doubt as to the nature of the disease. Coming from the Finsen Institute, which is devoted almost wholly to lupus, the author appears to represent this paper as a decisive advance in our treatment of the disease.

Diagnostic Valuation of Findings at the Apex.—Laser writes a short but timely article on this subject. His conclusions are as follows: Most women and many men show over the right lung apex a heightened breathing and especially a heightened and prolonged expiration over the right fossa spinata, occasionally also a weakened percussion sound. These findings, if accompanied only by indefinite symptoms like weakness, slight emaciation, and cough, are not to be regarded as evidence of apex tuberculosis. To insure the latter diagnosis there should be added rales, bacilliferous sputum, fever, etc. In doubtful cases tuberculin should be employed.

Deutsche medizinische Wochenschrift.

January 26, 1911.

Tertiary Febrile Syphilis of the Liver.—Kirchheim describes two cases of this affection, which is encountered now and then, and is perhaps not always one and the same affection. In the author's cases there were evidences of secondary infection. In other cases ulcerating gummata appear to be responsible; some such cases have yielded promptly to specific treatment. A case is known of a shopkeeper who fulfilled his duties for a long period and seemed in perfect health, although with an evening temperature of 105° F. He consumed large quantities of spirits daily, these evidently necessary in some way to his ability to keep up. Upon his decease the cause of death was given as syphilitic liver. Since the gummata show a marked tendency to affect the diaphragmatic aspect of the liver, especially the so-called hepatic ligaments, syphilitic liver may be secondary to intrathoracic syphilis. The author does not allude to the alleged belief that ordinary alcoholic cirrhosis of the liver may simulate ague, being characterized by periodical chills and fever. Malarial cirrhosis should certainly show this element. But while in the author's and other quoted cases gummata were apparently invariably present there is no mention of cirrhosis in any place. The process was, therefore, an acute gummatosis, and the question of fever with syphilitic cirrhosis would not be involved. Thus cases like the shopkeeper cited above may not necessarily belong under the present head.

Myeloid Chloroma.—Paulicek and Wutscher conclude that there is a transition between chronic myeloid leucemia and chloroma. Hitherto it has only been known that acute myeloid leucemia may be associated with myeloid. The origin of a chloroma from a persistent chronic myeloid leucemia speaks for a close association of the two affections. The development of an acute chloromatous process may be without influence on the blood picture of a previously existing chronic leucemia. It may be surmised that the green parenchyma here stands in association with the clumped accumulation of the most immature, rapidly growing myeloblasts. Radiotherapy ought to be of benefit in chloroma arising on a leucemic basis.

Physiological Action of Thallium.—Bushke has brought the subject of therapeutic action of thallium salts up to date. He states that with minimal doses of the acetate, or carbonate, an alopecia may be produced in mice, guinea pigs, apes, etc. This is usually located on the dormal surfaces of back, neck, and head, etc. In the rat, an alopecia universalis has been produced. In man and the rat a congenital arrest of hair growth may be produced, but this is not permanent. Thallium evidently acts centrally, and not peripherically.

Traumatic Sarcoma.—This problematic subject is taken up by Heinrich, who reports a case that agrees in certain respects with the essentials as laid down by Thieme, but differs in others. A perfectly healthy man severely barked his shin, somewhat high up. Iodoform was used at the time, along with adhesive plaster. The wound healed in fourteen days. But before this occurred severe pains had been felt, and a hen's egg size tumor had developed at the inner side of the wound, near the calf. The neoplasm remained stationary for months, and then took on an exacerbation. After considerable temporizing, a diagnosis of hematoma led to incision, with resulting recognition of a deep-seated sarcoma having central softening. An amputation in the thigh followed, but metastasis in the vertebral column led to death.

Münchener medizinische Wochenschrift.

January 24, 1911.

Forms of Action of Adrenalin.—It is well known that adrenalin has, in addition to a local action, several forms of general or remote action which are not entirely clear. Much seems to depend on the state of the circulatory organs at the time of an injection and whether these are normal or diseased, and von den Velden is certain as to two practically important actions of the drug at a distance, viz, a toning up or analepsis of the circulation and a remote hemostatic action. He appears to be dealing throughout with the intravenous method. The drug as tested on animals is efficacious in restoring compensation in various affections, although the intravenous method is also held by many to be dangerous to those with heart disease. It is evident that there must be strict indications and dosage. The author is at great pains to determine these by analysing material from all reported sources. He finds it of advantage to inject half a milligram of the drug beneath the skin, using the synthetic preparation. In the relatively normal subject there follows little or no change in the blood-pressure, but in the presence of a bacterio-toxic affection of the circulatory organs the blood-pressure is notably affected—as in pneumonia, sepsis and typhoid. Tests of the blood were made in a number of such cases for the presence of antibodies, etc. The author sums up by stating that in pure cardiac insufficiency unconnected with a septic condition of the blood, adrenalin may be used for days in succession with benefit—naturally, in combination with other substances. The remarks on the styptic action apparently represent no advances on our present knowledge.

Differences in Local Sensitiveness to Iodine.—This subject has been recently agitated, and Fleischmann gives his personal experience. The author does not include the chief regions affected in iodide idiosyncrasy. He notes a marked sensitiveness of the vascular system, of the nervous system, and metabolism. These all point to the liberation of thyroid matter, in other words, to a thyreotoxicosis. It was noted years ago that goitrous subjects were intolerant of iodine; and not only these but healthy subjects in goitrous localities. The author, however, has found that of a large number of patients who showed acceleration of pulse after taking iodine only 16 per cent. or so had enlarged thyroids; while numerous goitrous subjects did not show this reaction. Nevertheless, it remains true that in a goitrous country supersensitiveness to iodine is common, irrespective of whether the patient has visible goiter or not.

The Cervical Cesarean Section.—Walcher reports a few cases of this operation, and concludes therefrom in the great majority of cases the classic abdominal section is not preferable. The cervical transperitoneal section has proved satisfactory as a routine procedure and has done away to an increasing extent with hebeosteotomy, perforation of the living child, high forceps, etc.

Albuminuria and Cylinduria Resulting from Constipation.—Kobler refers to his priority in the discovery of this condition, which has also been described by Wasserthal and Ebstein.—*Wiener klinische Rundschau.*

Book Reviews.

Die Fäzes des Menschen im normallen und krankhaften Zustande. Mit besonderer Berücksichtigung der klinischen Untersuchungsmethoden. Von Prof. Dr. Ad. Schmidt, Direktor der medizinischen Klinik an der Universtät Halle, und Prof. Dr. J. Strasburger, Leiter der Ambulanz und der hydrotherapeutischen Abteilung der medizinischen Univ.-Klinik zu Bonn. Dritte, neu bearbeitete und erweiterte Auflage. Mit 15 lithographischen Tafeln und 16 Figuren im Text. Berlin: Verlag von August Hirschwald, 1910.

The rapid growth during the past few years of the literature pertaining to coprology has been the occasion of the revision of this standard work, which has also been considerably enlarged. The recent advances in the study of the feces have been the awakened interest in the diagnostic significance of its proteids and its ferments; the improved methods of fat and cellulose determination, the bacteriology and the enumeration of the bacteria. A series of hemolytic and specific substances, pentose and hemicellulose, have also been the subject of research. All these investigations are thoroughly presented in this new edition, which, like the former editions, is intended primarily for the general practitioner, placing greatest emphasis upon the macroscopic and microscopic examination of the feces; it is realized that the chemistry and bacteriology of the feces are of greater interest to the laboratory investigator. This work is a complete exposition of the subject, valuable for both study and reference. The sixteen colored plates are remarkable for their artistic execution.

The Cause and Cure of Colds. By William S. Sadler, M.D., Professor of Physiologic Therapeutics, the Post-Graduate Medical School of Chicago, Director of the Chicago Institute of Physiologic Therapeutics, Member of the American Medical Association, the American Association for the Advancement of Science, etc., etc. Author of "The Science of Living; or, The Art of Keeping Well." Illustrated. Chicago: A. C. McClurg & Co., 1910.

This small volume of 150 pages has been written for the laity. It is based largely upon the author's Chautauqua lecture, "Catching and Curing a Cold." Most of the books on medical subjects which are written for the enlightenment and guidance of the laity are of no value to the physician and of questionable value to the layman. If the author had limited himself to the discussion of the nature and cause of common colds and their prophylactic and general treatment we might have been willing to call this book an exception. But the author goes further. He gives rules for the treatment of severe and protracted colds and influenza, giving their differential diagnosis, and adding certain prescriptions for nasal sprays. To be sure he advises that a physician be called in all such severe cases, but leaves it to the patient to diagnose his own condition. While such a book might have some worth for the few who are where medical advice cannot be easily obtained, it is apt to be dangerous rather than helpful if it encourages self-medication.

Éléments d'anatomie Pathologique. Par le Dr. L. Bériel, Chef des travaux d'anatomie pathologique à la Faculté de Lyon, Médecin des Hôpitaux. Avec 232 figures desinées par l'auteur. Paris: G. Steinheil, Éditeur, 1910.

This small volume is intended as an introductory textbook in pathology for students. It plunges immediately, without preliminary general discussions, into the subject of normal histology, in order to help the student in the study of the abnormal. Nutritional lesions cover fatty, hyaline, and amyloid degeneration. Hypertrophy and atrophy also come under this head. Inflammation is accorded but twenty pages, tuberculosis and syphilis being included. Special pathology is then taken up, beginning with the lesions of the lungs. A few pages are devoted to the digestive tract, liver, and genitourinary system. Less than fifty are allowed for the nervous system. On the whole this portion of the book is simple but very superficial; it is totally different from the ordinary textbook of pathology in which one expects a rather full enumeration of the different lesions, or at least references to articles where the matter can be studied in detail. In this volume, however, practically all references have been omitted, and the discussion of any one point has been kept down as much as possible, and only well-known facts are considered. The third portion, which deals with tumors, is somewhat more satisfactory. It occupies about two hundred pages and gives, in a fairly complete manner, those aspects of the subject with which students should be familiar. The print of the book is excellent; the paper is good; and the book is well bound. The cuts are rather crude, a good many of them in outline or on stipple paper, and not what we are apt to expect of the best French work. As diagrams, however, they are satisfactory. Within its limitations the book is a fairly satisfactory one-volume text for students only.

Motherhood. A Manual on the Management of Pregnancy, the Preparations for and Conduct of Labor, the Care of Mother and Child after Labor, and the Principles and Methods of Infant Feeding up to the Third Year of the Child's Life. Prepared especially for mothers, nurses, and students of medicine. By Hudson D. Bishop, M.D., Visiting Obstetrician to the Maternity Hospital, Cleveland, Ohio. Cleveland: Rose Publishing Company, 1910.

The author has sought within the narrow confines of this book "to give everything that either the mother or nurse should know regarding the management of pregnancy, labor, and the lying-in, together with the care and feeding of the child." The mother is therefore told all about eclampsia, postpartum hemorrhage, puerperal infection, etc., in the detail such as is found in works on obstetrics. This is not very cheerful reading for the expectant mother, and hardly what her physician would care to have her read. A book cannot serve the needs of the nurse, the physician, and the mother at the same time, and the failure of the author to realize this impairs the value of his book. The same inability to appreciate this fact is manifested in the discussion of the caloric values of infant feeding. This is out of place in a practical book for mothers.

A Laboratory Text-Book of Embryology. By Charles Sedgwick Minot, LL.D. (Yale and Toronto), D.Sc. (Oxford), James Stillman Professor of Comparative Anatomy in the Harvard Medical School, President of the Boston Society of Natural History. Second Edition, revised, with 262 illustrations, chiefly original. Philadelphia: P. Blakiston's Son & Co., 1910.

The second edition of Minot's "Text-Book of Embryology" has been considerably increased in text and in the number of illustrations. It is not intended to be a book of reference for minute embryological details; but is rather a practical laboratory guide to be employed by the student in a systematic study of mammalian embryology. The illustrative material is drawn chiefly from the pig and human embryos. The cuts are simple, somewhat diagrammatic, but admirably adapted to their purpose. The text is clear and complete within the limitations set by the author. A chapter on the chief technical methods employed in embryology is appended to the volume.

A Treatise on Orthopedic Surgery. By Royal Whitman, M.D., Assistant Professor of Orthopedic Surgery in the College of Physicians and Surgeons of Columbia University, New York; Professor of Orthopedic Surgery in the New York Polyclinic Medical School and Hospital; Associate Surgeon to the Hospital for Ruptured and Crippled; Orthopedic Surgeon to the Hospital of St. John's Guild; Consulting Surgeon to St. Agnes Hospital for Crippled and Atypical Children, White Plains, and to the New York Home for Destitute Crippled Children; Member of the Royal College of Surgeons of England; Member and Sometime President of the American Orthopedic Association; Corresponding Member of the British Orthopedic Society; Member of the New York Surgical Society, etc. Fourth Edition, revised and enlarged; illustrated with six hundred and one engravings. Philadelphia and New York: Lea & Febiger, 1910.

This work has made its own reputation in its three previous editions. The present edition has been thoroughly revised and has had new material and new illustrations added. The importance of tuberculosis in orthopedic surgery is emphasized by giving separate chapters to tuberculosis of each part, the chapter on non-tuberculous diseases following immediately after. The book is extensive and full, filling over 900 pages. The text is clear and accurate, the passages on the operative procedures being especially detailed and descriptive. One smaller feature which might be changed is the placing of the general chapter on tuberculous diseases of the bones and joints, as Chapter V instead of Chapter I. The arrangement is illogical and requires frequent references to the later chapter in the first chapter of the book. This makes reading awkward. In general, however, the work is well arranged, clear, and full. The illustrations are excellent and serve well to explain the text. They are not added merely for ornamental purposes. The type is large and clear. The book may well be recommended to any one desiring an up-to-date work on orthopedic surgery.

Society Reports.

NEW YORK ACADEMY OF MEDICINE

SECTION ON PEDIATRICS.

Stated Meeting, Held January 12, 1911

DR. THOMAS S. SOUTHWORTH, CHAIRMAN PRO TEM.

A Case of Congenital Goiter.—Dr. EDWARD W. PETERSON presented this case. The patient, a female child, was admitted to the hospital on January 18, 1905, at the age of five weeks. There was no history of syphilis, tuberculosis, cancer or goiter in the family. The child was normal except for the swelling on the right side of the neck. There had been no dyspnea nor inconvenience whatever. The tumor filled the submaxillary space and extended downward nearly to the clavicle. The surface was moderately firm and it did not fluctuate at any part. Below and to the sides distinct nodulation was felt. The tumor was dissected out and several times during the operation the child ceased to breathe. Artificial respiration was employed for twenty hours after the operation. Except for a high temperature, 105° F., and a slight bronchitis nothing unusual occurred until the ninth day, when the child had a convulsion which lasted five minutes. On the thirteenth and fourteenth days there were twitchings and convulsive movements. As soon as it was discovered that the tumor was thyroid it was believed that the whole gland had been removed and thyroid extract was administered. Within twenty-four hours the tetany ceased. Except for a few minor ills the patient had been healthy. The points of interest were the presence of a congenital tumor of the neck which proved to be goiter, the abnormal location of the thyroid gland, the accidental complete thyroidectomy, the development of tetany and its disappearance after the administration of thyroid extract and the subsequent normal physical and mental development of the child. The questions which arose were whether all the thyroid tissue had been removed; why tetany developed; and whether the child would continue to develop normally.

Dr. FREDERICK E. SONDERN made the pathological report. The tumor was horseshoe in shape; one side was composed of a large elongated tumor measuring 6 cm. in length, 4 cm. in width and 3 cm. in thickness; the other side was composed of a smaller tumor, the two parts being joined together by an isthmus of fibrous tissue. Both parts presented a slightly irregular lobulated appearance and both showed the same structure, which was that of the thyroid gland. The acini had undergone a slight adenomatous proliferation and were filled with a very dense colloid material, the greater number of them being distended by it to the dimension of small cysts. The epithelium was very much infiltrated, but showed no signs of malignant proliferation. The entire growth was surrounded by a thin fibrous capsule. The diagnosis was adenoma and colloid degeneration of the thyroid gland (goiter).

Dr. JOHN ROGERS said that the question arose in his mind as to whether all the thyroid gland had been removed. He did not think it possible for a child to develop as this one had without any thyroid tissue. A case had been reported some time ago in which sections of the heart muscle showed two distinct masses of thyroid one-quarter of an inch in diameter imbedded in the muscle. There was no doubt but that in a few cases apparently without thyroid glands thyroid tissue was located somewhere in the body. The question of the origin of such a condition was both curious and interesting. It was said that in the fetus this gland did not functionate until between the seventh and eighth month. From that time the colloid material might have collected and acted. Possibly there might be some obstruction to the outlet of this colloid material developed during fetal life from a chronic strumitis. The child might have to be fed thyroid some time in the future in order to secure good health, especially at the time of puberty, when thyroid symptoms were very likely to be shown. He thought the child should be carefully watched.

Dr. A. JACOBI said it was only the right lobe of the thyroid that had been removed. A congenital goiter was apt to grow in all its parts and therefore the case presented was an exceptional one. If both lobes of the thyroid had been removed together with the isthmus the probabilities were that the child would have suffered more from the beginning of the disease. The probability was that the parathyroids had been removed as well, and this would explain the occurrence of tetany at the time. It was stated that the tumor was located high up; that was explained by the fact that the thyroid in the fetus and in young babies was situated higher than in the adult. All cases of congenital goiter were of that nature and, therefore, it was easy to mistake one for hygroma. A simple hygroma might be found in this same situation and without a microscopical examination a mistaken diagnosis was easy to make. Dr. Jacobi said that in looking over European literature it was a surprise to note how many more cases of this nature were reported abroad than in this country. Many cases of goiter that were not considered congenital were so in fact. Sarcoma of the kidney was seldom observed in babies by the mothers before the children were two, three or four years of age and yet many were congenital. Likewise, many cases of goiter were not observed because they were too small and did not give rise to symptoms of a serious nature. One should always look for colloid material in these cases, which might have been present at an early time and disappeared afterwards under pressure from growing intercellular tissue. The result in the case under discussion was a fortunate one both for the doctor and for the patient; they saw very few such cases. In Demme's work published years ago it was stated that among 650 cases of goiter in the young 50 odd cases could be traced to congenital origin. If Demme were alive to-day he might be able to collect 1,000 more such cases.

Dr. GEORGE DOW SCOTT reported some experimental work done with pituitary gland extract (Beebe's) in a case of cystic goiter; there followed a disappearance of the tumor in a short time.

Dr. EDWARD W. PETERSON said that the operation was undertaken with the diagnosis of lymphosarcoma. The specimen presented showed two lobes joined together by an isthmus. The result of the work in this case was certainly very satisfactory.

The Proper Management of Foundlings and Neglected Infants.—Dr. HENRY DWIGHT CHAPIN read this paper. (See page 283.)

Dr. A. JACOBI said that the mortality of infants under six months of age was very high, about 40 per cent. Every possible care should be taken of them from the beginning; they should be given the best of surroundings, the best nursing and the best care possible; if this was done the mortality would not be so high as 40 per cent. for infants under six months of age. Under ordinary circumstances the average mortality of children under one year of age was about 29 or 30 per cent. The cases referred to by Dr. Chapin were not only sick babies but well ones also, and this should be borne in mind when a mortality of 40 per cent. was referred to. This was a high mortality for the average child. Dr. Jacobi said he had had many experiences and he recalled the time when he kept the books of a certain institution in which were small babies; no baby ever came into that institution at an early age and remained there three months and lived. In that insti-

tution of which he was the nominal head the mortality rate for babies but a few months old was 100 per cent. Therefore, Dr. Jacobi said, he knew something of the difficulties which attended the care of such little ones in institutions. In this particular institution there was too much interference. There were a few dozen superintendents; these ladies with their long trails came in once a week, walked up and down the room or ward, with too much to say, always finding fault with the nurses and doctors and others connected with the institution. For instance, Dr. Jacobi told the matron to remove some heavy curtains from the babies' cribs. She refused; therefore, Dr. Jacobi himself removed them. This was in July when the babies were sweltering and perspiring and tortured. On the same day in came a high official and asked why the curtains were removed and Dr. Jacobi replied, "Simply because I did not want the babies suffocated; therefore, I took them off." This was an instance of how such institutions were run forty years ago. In looking over the records of that institution Dr. Jacobi found that every baby that lived there three months was a dead baby. This fact he called to the attention of the directors and proposed that the babies be farmed out; the result was that Dr. Jacobi was asked to resign; he told them he preferred to be expelled and expelled he was. Forty years ago the farming out of babies was not consented to until after his expulsion and he hoped and trusted that Dr. Chapin would have better results and that all present would do everything in their power to aid him in carrying on the work which was outlined in his paper. In an address delivered many years ago before the Medical Society of the County of New York he had the following to say concerning the infant asylum foundlings. "The whole administration of the foundlings ought to be controlled by the commonwealth. Both private and sectarian establishments ought to be under governmental supervision; ought not to be supported or aided by the State, but not interfered with so long as their successes and general management appear satisfactory; the department of the foundlings to be centered in one office; the necessary appointments of the head or heads to be made by the Governor of the State; the expense of boarding the foundlings, except those in private or sectarian institutions, to be borne by the people of the State of New York." This was Dr. Jacobi's opinion of the responsibilities and duties and the rights of the State. In 1871 the printed minutes of the Commissioners of Public Charities and Correction contained a proposition to make preparation for boarding out infants, submitted by the Medical Board of the Infants' Hospital, Randall's Island. A paper was prepared, which was intended to be circulated over the signatures of the Commissioners; they considered the publication impracticable at that moment, but they approved and endorsed all its contents. Dr. Jacobi read this paper.

Dr. S. Josephine Baker, Director of Child Hygiene, Department of Health, said that the mortality rate as given by Dr. Chapin was particularly interesting because it was taken from both the convalescent and sick babies. It should be remembered that foundling institutions received both sick and well children. Dr. Baker presented a map of the Borough of Manhattan which, by means of colored pins, showed every death under one year of age that had occurred during June, July, August, and September, 1910, in private homes, in institutions, etc. It was shown that from May to November (six months) the mortality in three foundling hospitals was 18 per cent. of the total mortality of the Borough of Manhattan. The deaths from diarrheal diseases among infants under one year of age gave a mortality of 19 per cent. of the total Borough death rate. A large number of the diseases were nutritional. In one institution where about 70 per cent. of the children were boarded out a larger number died from nutritional diseases, from inanition and congenital diseases; in the two other institutions the highest mortality was from diarrheal diseases. The number of deaths among the children under three months gave a mortality of 56 per cent. of the total number of deaths occurring among children under one year of age. Of the total institutional deaths it was found that 6 per cent. were babies previously placed out to board in homes, artificially fed; this was compared with 45 per cent. of the mortality of those artificially fed in institutions. The deductions to be drawn were obvious. There was no doubt but that that mortality rate in institutions for babies was high. Dr. Baker agreed with Dr. Jacobi that it was time to consider the situation seriously when institutions furnished 18 per cent. of the total mortality during the summer months; this merited the attention not only of the medical profession but of health authorities and of everybody who was interested in the social and economic aspects of the situation. To lower the death rate among babies required that more children be placed out in homes as advocated by Dr. Chapin.

Dr. Francis H. Glazebrook of Morristown, N. J., said that the features of the Speedwell method which most appealed to him were as follows: (1) There was no limit to the age at which a child was received: any little one from a day old was provided for. (2) There was no limit to the number of children taken; it was simply a question of sufficient funds. (3) There was no limit to their length of stay, they preferred to keep them until strong and healthy. He wanted to correct the prevailing impression which was evident from the discussion that they were dealing with well babies. The Speedwell Society had no use for well babies. Their cases were of the severer types of malnutrition; the cases reported would practically have died under the hospital methods of treatment. They were most interested in young babies suffering from atrophic diseases and malnutrition; this was the class of cases in which the Speedwell Society got the best results. They never returned babies because they were going to die. They had seen such wonderful recoveries in what looked like hopeless cases that even the foster mothers never gave them up. Out of nearly 1,500 children treated since the beginning of this work, they had only sent back of their volition 33; most of these were cases which developed some condition which required hospital attention, and some were returned by the request of the parents who, thinking they would die, preferred to have them die at home. Their babies suffered very little from diarrhea. They had no specific method of feeding; the babies were fed on the common sense plan; they usually continued the food that the baby was getting when brought to them. If the food did not agree after a fair trial it was then changed. There were three employees. The superintendent, or matron, whose duty it was to find the homes, to get the babies and to return them to their homes when well, and follow them up as much as was possible. The nurse visited all the cases every day, superintended the feeding, the general care and management, and reported to Dr. Glazebrook every night or oftener if necessary. Occasionally they had difficulty with a woman in getting her to carry out orders explicitly; at the same time there was a demand for these babies. The twelve dollars ($12.00) a month which was paid to the woman for her keep was a good deal of money to them. This part of the work was a charity; it helped to pay the rent and kept together their little homes. The women soon learned that unless they did as they were told the babies would be taken away from them.

Dr. Rowland G. Freeman said that there was no doubt but that there were many advantages attending the farming out of babies but the figures that had been presented accentuated the disadvantages of institutions and the ad-

vantages of boarding out; for instance, Dr. Baker had stated that babies were brought to the institutions healthy; then they became sick and died. The exact conditions in these institutions were little understood. They all believed in the boarding out system and used this method so far as possible. Most of the children when sent to the institutions were far from well, many of them suffering from hereditary syphilis, others from the result of neglect. The children that were boarded out were the best ones that had been sent to the institutions because these women would not take unpromising children, and the same was true of the wet nurses, so that the best children were boarded out and the worst were left to the doctors to feed in the institutions, and the successful feeding of such children was a most difficult problem. Moreover, the boarded out children, if they did badly or became sick, were returned to the hospital, and frequently died there. This again diminished the mortality of the boarded out children and increased that of the institutions. The figures presented, therefore, giving the relative mortality in children boarded out and in institutions needed material qualification. The ideal method would be to wet nurse the poor babies and artificially feed the better ones, but this system had not yet seemed possible. With regard to the so-called hospitalism, this did not exist in all institutions. The babies, in some institutions, did very well; and their mortality compared fairly well with that given from Morristown; even with artificial feeding they often showed a low mortality. The amount of money paid for the care of these babies in institutions was insufficient for the purpose. It was said that the cost of the care of one baby in some institutions was $1.50 a day; he understood that it cost the City of New York $1.07 at Randall's Island. The city gave these institutions forty-five cents a day for every child under the age of two years, and thirty-five cents when they were over two years, which amount was wholly inadequate.

Dr. Henry Koplik said that he appreciated the fact that any discussion on mortality statistics was very unsatisfactory and very unfair. There was a distinction to be made between the healthy baby of one year and the sick one. Decided efforts should be made to get people to care for these infants. When a baby similar to the atrophic babies of Dr. Chapin was admitted into the hospital wards, it was apparently a hopeless task to attempt to feed it. Dr. Chapin's plan was the best and it was a pity that it was not in more general use. In hospital wards patients who were cured of enteritis became trophic if retained there. If sent to their homes they relapsed. Some babies disappeared from one hospital only to turn up in another. The great problem that confronted those interested in the care of infants was what to do with these babies when they were discharged from the hospitals.

Dr. Sidney Haas called attention to the relative cost of maintaining babies in institutions and outside and said that institutions could not be run at the rate of $12.00 per month per baby. The cost per child should not be less than five dollars per week.

Dr. Chapin in closing the discussion, said that these 241 babies would have died in institutions with every window open, so that 60 per cent. was a good figure among such young children. The average time the babies were left in homes was about four months; they were kept there until they were really better. Among 1,386 cases, the average time was four months. After eight years' experience with this system they were able to report favorably. Photographs were shown of atrophic, under-nourished infants before they were sent out from the institution and others were shown of the same infants some months later, demonstrating the marked improvement after four months' farming out.

Pathological Society of Philadelphia.

At a stated meeting held November 10 Dr. P. G. Skillern presented a specimen of "Ossifying Periosteal Chondrosarcoma of the Fibula." The part was removed by amputation and the growth, of considerable size, was found to involve only the lower fourth of the fibula, leaving the tibia entirely free. Dr. David Riesman and Dr. Daniel Longaker reported a case of "Septicemia from Gangrene of the Lung," and they demonstrated the specimen. The patient was a multipara and the delivery was normal and uncomplicated. A putrid uterine discharge developed, with symptoms of profound intoxication and subcutaneous emphysema. The last was thought to be due to the activity of the *Bacillus aerogenes capsulatus*. Death resulted and on post-mortem examination the uterus was found gangrenous, staphylococci being found in this organ and in the blood. The *Bacillus aerogenes* could not be isolated, and it was thought from the presence of air beneath the capsule of the liver and between folds of the mesentery, as well as beneath the skin, that some other air-producing bacterium had been at work. It was also suggested that the emphysema might have resulted as an accident in the practice of subcutaneous infusion in the course of treatment. Dr. David Riesman and Dr. John M. Fisher presented a specimen of "Gangrene of the Uterus and Pyonephrosis." The patient was a primipara who presented a fluctuating swelling in the left loin, in conjunction with symptoms of septicopyemia. The condition was not favorable for operation, and a fatal issue resulted. On post-mortem examination the uterus was found gangrenous, the left ovarian artery occluded by a thrombus, and the left kidney converted into a huge pyonephrotic sac. Dr. Wm. Pepper exhibited "Specimens of Trichinosis." The patient was a man who had variously partaken of sausage, pork, ham, etc., always cooked according to his statement, and who presented swelling of the face, especially below the eyes, and striking edema of the bulbar conjunctiva, in conjunction with pain in various situations. The first examination of the blood disclosed no abnormality, but the second and subsequent examinations disclosed a marked increase in the number of eosinophile leucocytes. Subcutaneous nodules were now detected, and bits of tissue were excised, sectioned, strained, and examined microscopically, with the discovery of trichinæ in an early stage of deposition in the muscles. Larvæ could not be found in the circulating blood. Dr. Josephus T. Ullom presented a communication entitled "The Wassermann-Noguchi Reaction: Its Technique and Conclusions." He defined the several terms employed in connection with the serum complement-reaction, and he described its mechanism, together with the procedures carried out in its practice, as well as the results obtained in a series of personal observations. The reaction was obtained in all of the cases of primary syphilis, in a smaller proportion of cases of secondary and tertiary syphilis, and also in parasyphilitic conditions. The reaction may not be present in the first days of the disease, but, as in the case of the agglutination test, some days must elapse before it makes its appearance. A positive reaction is almost conclusive evidence of the existence of syphilis, while a negative response, to be valuable in this connection, must have occurred on several successive occasions at varying intervals. Dr. A. E. Taylor presented a communication entitled, "The Ammonia Output in Urine." He cited observations to show that the high figures generally given for the normal urinary ammonia output are based upon error, decomposition of the urea taking place in specimens kept at room temperature, whether preserved by the addition of such substances as thymol or chloroform or toluol or not, and that this error can be obviated by examining the urine immediately on its voidance or by preserving it in the refrigerator at a uniform temperature of 40° F.

At a stated meeting, held December 22, Dr. D. Rivas exhibited specimens of "Male and Female Trichina," obtained from the intestinal canal of rats, to which had been fed trichinous muscle from infested human beings. Dr. J. H. Austin demonstrated a specimen of "Multiple Congenital Hemangioendothelioma of the Liver." The specimen was obtained from the body of a child, ten weeks old, one of twins, the other child being well. The liver was thrice the normal size, and it was studded with nodules of varying size, presenting a reddish center surrounded by a light zone and this in turn by a reddish zone. Histological examination disclosed the structure of a hemangioma, together with the presence of endothelial cells. The condition is exceedingly rare, perhaps not more than two cases being recorded in the literature. Drs. J. F. Schamberg and S. Strickler presented a communication entitled "A Preliminary Report on the Occurrence of Eosinophilia in Scabies." They reported a series of observations showing that in sixteen of nineteen cases of scabies a moderate degree of eosinophilia, up to ten per cent., was present. Drs. Paul G. Weston and John A. Kolmer presented a communication entitled "A Guinea-pig Test for Determining the Virulence of Diphtheria-bacilli." They pointed out the importance of establishing in cases of angina and of nasal and aural discharge and following attacks of diphtheria whether bacilli having the morphological appearance of diphtheria-bacilli were pathogenic or not. Staining methods and culture methods may fail in this connection, so that it may become necessary to resort to inoculation of guinea pigs and determine their reaction in order to establish the virulence of the bacteria in question. Dr. Howard T. Karsner presented a communication entitled "The Lungs in Anaphylaxis and in Conditions Simulating Anaphylaxis." Dr. Randle C. Rosenberger presented a communication entitled "The Presence of Intestinal Parasites in the Inmates of the Philadelphia General Hospital." More than 1200 examinations of stools were made and a large variety of parasites were found. Especially in the inmates of the insane department were amebæ found in almost every instance, although dysentery and abscess of the liver were practically unknown among these patients.

College of Physicians of Philadelphia: Section on General Medicine.

At a stated meeting held January 23 Drs. Lewellyn F. Barker of Baltimore and Walter B. James of New York presented communications discussing the "Electrocardiogram in its Relation to the Physiology, Pathology, and Diagnosis of Heart Disease," with lantern illustrations. Dr. Barker devoted his paper to a very thorough discussion of the electrical and mechanical principles underlying the construction of the apparatus and he also described its mode of employment. By means of a registering device a record is made of the movements of a string galvanometer induced by the differences in electrical tension in various parts of the heart. Dr. James presented an interesting paper in which he related in detail the results of a study of the clinical application of the apparatus showing its usefulness in determining or confirming the existence of various derangements in the action of the musculature of the several parts of the heart, such as are seen in heart block, extrasystole, hemisystole, fibrillation of auricle or ventricle, and various other abnormal conditions met with in the heart. The diagnostic information thus gained may be put to practical use in the way of its prognostic application and likewise to therapeutic use. Tracings from illustrative cases were thrown upon the screen. The discussion was participated in by Drs. James C. Wilson, Alfred Stengel, George W. Norris, Wm. S. Wadsworth, and David Riesman.

Medical Items.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week of February 11, 1911.

	Cases	Deaths
Tuberculosis Pulmonalis	550	190
Diphtheria	299	32
Measles	347	13
Scarlet Fever	522	16
Smallpox	—	—
Varicella	178	—
Typhoid Fever	31	7
Whooping Cough	101	7
Cerebrospinal Meningitis	5	4
Malarial Fever	—	—
Totals	2,033	269

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended February 10, 1911.

PRELIMINARY REPORT OF CASES TREATED BY THE EHRLICH-HATA "606" INJECTION.

By CHARLES H. CHETWOOD, M.D.,

NEW YORK.

PROFESSOR OF GENITOURINARY SURGERY, NEW YORK POLYCLINIC MEDICAL SCHOOL AND HOSPITAL; ATTENDING GENITOURINARY SURGEON TO BELLEVUE HOSPITAL; CONSULTING SURGEON TO J. HOOD WRIGHT HOSPITAL AND TO ST. JOHN'S HOSPITAL, LONG ISLAND CITY.

The professional community, as well as those outside the profession, during the past few months have been not a little aroused over the startling announcement of the discovery by Ehrlich of Frankfurt of a new specific remedy for syphilis, popularly known as "Ehrlich's 606" and latterly designated Salvarsan.

As extravagant as the claims may seem in connection with this new discovery it must needs be received with a proportionate respect due to the scientific standing of its discoverer, who has developed by laboratory experimentation the rationale or theory upon which the specific action of this agent is explained in the so-called "therapia sterilisans magna," or complete sterilization of the organism with respect to the special parasites infesting it, the *Treponema pallidum* (or spirochete). In a word, Ehrlich has found, by animal experimentation and clinical experience, that it is possible to introduce into the system a powerful chemical antidote, which, while it exerts destructive influence upon the particular parasite for which it has a special affinity, does so without dangerous action to the organism, except in certain contraindicated conditions.

It is not the purpose to attempt a critical review of the subject in general. The current journals, foreign and domestic, contain the reports of all the important investigators, with an outline of the cases in the various stages, that have been subjected to this most recent method of treatment. It is more the object of this presentation to contribute some knowledge upon the subject to the stock that is being collected from every source for the purpose of reaching a fair and reliable conclusion as to the immediate and ultimate results to be expected, by recording a concise and dispassionate recital of personal experience.

In an investigation of this importance every little counts and the expectation of a later more complete and amplified report is the excuse for this present preliminary one.

The first series of 8 cases in which the "606" injection has been personally employed by the writer are, briefly, as follows:

Case I. *Tertiary Syphilis.* Multiple bony nodes, involving right clavicle and inner condyle of right tibia. A relapsing case in spite of several vigorous mercurial courses, supplemented with increasing doses of potassium iodide. Wassermann positive.

Case II. *Fungating Condylomatous Patches* involving the inner surface of both thighs at the junction of thigh and pelvis. Primary sore 22 years ago. Very little treatment. Wassermann negative.

Case III. *Tertiary Syphilis,* involving a periosteal node of the frontal region. Swelling of right foot and typical scar pitting of the nose and face. Primary sore 8 years ago. Wassermann positive. This patient was unable to take iodide of potassium and was suffering intensely with nocturnal pains in the head, producing insomnia.

Case IV. A young man with *Incipient Syphilis,* early secondary stage, who was injected in compliance with his urgent demand. He was suffering from severe nocturnal pains in the head, chest, and lower vertebral region. Had had injections of salicylate of mercury. Wassermann positive.

Case V. *Tertiary Syphilis.* Periosteal node of right tibia, gummatous in character, and painful thickening of other bony areas. Chancre in 1901. Wassermann positive.

Case VI.—*Papulo-squamous Circinate Patches of Hands, Arms and Face,* in a patient who tolerated mercury badly, and not in sufficient dosage to control lesions. Disease dates back 3 to 4 years, during which period she has been under almost constant treatment. Wassermann positive.

Case VII.—*Bilateral Syphilitic Orchitis.* Sore 3 years ago. Little treatment. Wassermann positive.

Case VIII.—*Secondary Ulceration of Fauces and Ulceration of Forearm.* Some internal hypodermatic treatment. Sore last April. Wassermann negative.

In the eight cases there were 3 tertiary bone lesions; 1 tertiary skin lesion; 1 late secondary skin lesion; 1 primary and beginning secondary stage; 1 syphilitic orchitis; 1 secondary lesions of fauces and forearm.

Treatment. Mercury and potassium iodide more or less continuous in 3 cases; very little in 4 cases; beginning tretament in 1. Pain was intense at the site of injection for 24 or 48 hours in all cases, and persisted for the greater part of a week in over half of them. The temperature reaction was not marked in any. A detrimental effect noted in none of them. Dosage: in 6 cases, 0.5, 0.55 in 1, and in one, 0.6 gm.

The powder, which is provided in a vacuum tube, is mixed with a small amount (3 or 4 c.c.) of distilled water, to which is added 2/5 or 3/5 c.c. of 15 per cent. sodium hydroxide. This is carefully mixed in a glass mortar until all granules of the powder disappear and a thoroughly homogeneous mixture is obtained. Enough distilled water is then added to bring the total quantity up to from 18 to 20 c.c., together with an additional quantity of sodium hydroxide of 2/5 or 3/5 c.c., which is mixed in slowly, simultaneously with the addition

of the distilled water, and has the effect of helping to make a good solution, but which is not permanent, and should be used promptly after mixing.

The injection is made in 2 sections of 10 c.c. each into the two gluteal regions.

Results. Symptoms improved markedly in all, and practically disappeared in 7 within 2 weeks after injection.

Relapses. Partial relapse in 1 case (No. II), which proved to be temporary. Complete relapse in 1 case (No. III) at end of 4 weeks.

Wassermann reaction before injection positive in all but one in which it was negative both before and afterward, in spite of the disappearance of the lesion. Of the other seven three have yielded a positive reaction at the end of about a week, and one a positive reaction at the end of two weeks following injection. In three it has not yet been taken.

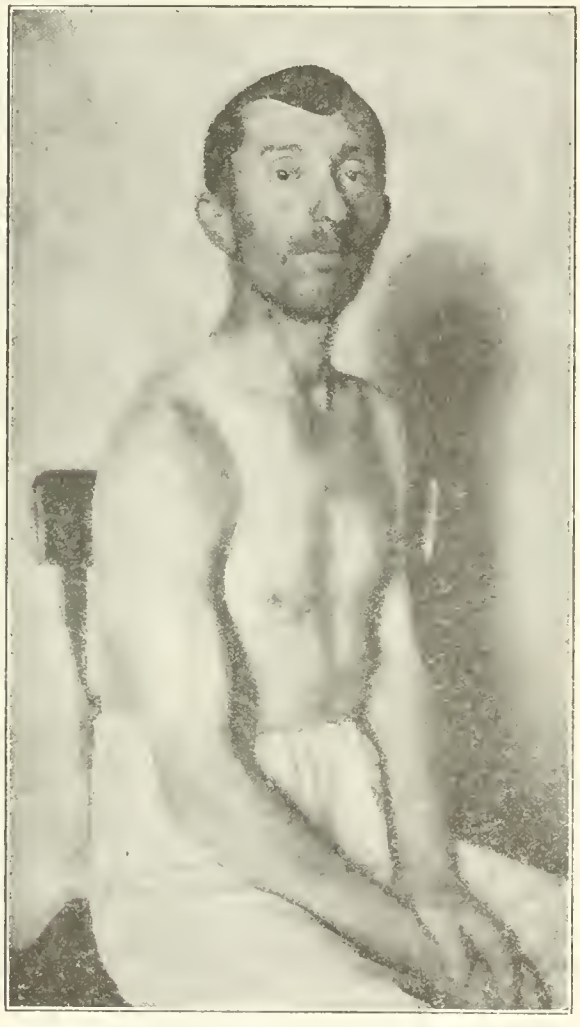

Fig. 1.—Case 1, syphilitic node before treatment.

The clinical histories of these cases in detail are as follows:

Case I.—Chancre, followed closely by right-sided bubo in 1906. He was in the hospital for 5 weeks, and under local treatment the chancre healed. Gives no history of secondaries. Six months later deep ulcers appeared on the thighs. He entered a city hospital and was treated with mercury and potassium iodide, and the ulcers healed in 20 days. There were no symptoms until September, 1909, when he developed a swollen right knee, which was tender and painful. There was a hard, nodular swelling at the right sternoclavicular articulation, and severe pain in right shoulder. After a short course of hospital treatment the swellings diminished and his general condition improved.

In October, 1909, he returned with a gumma on the left side of the frontal bone, and was treated with injections of mercury and potassium iodid by mouth. The gumma disappeared, and he continued to take the potassium iodid for about four months after leaving the hospital. November 7, 1910, readmitted to Bellevue Hospital with a recurrence of symptoms in the right knee and right shoulder. There is a nodular swelling of the right sternoclavicular articulation, 3 cm. long and 2cm. broad, a swelling over the ninth rib in the mid-axillary line, and a gummatous ulceration of the fauces. Wassermann reaction positive.

November 15, 1910, "606" in dosage of 0.6 gm. injected in both buttocks by the writer. During the following forty-eight hours patient complains of considerable pain at the site of injections, and there is marked induration of the right buttock. Several small red papules appear on the back. Throat markedly congested, with ulcerated areas at back. Temperature 102° F. in first twenty-four hours. November 21, 1910, Wassermann reaction positive.

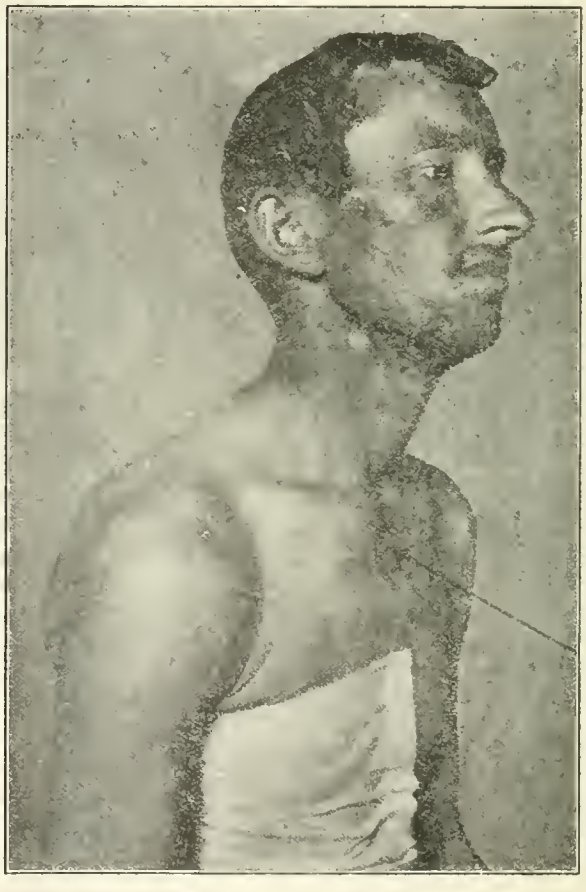

Fig. 2.—Case 1, after treatment

Ten days after injection he shows decided improvement. There is practically no pain or tenderness over gummata, and comparison of the *x*-ray taken before injection with that taken afterward shows that the tumors are all markedly diminished in size. The congestion of the throat has disappeared, leaving a scar at the site of the previous ulceration. The patient is up about the ward, and in good general condition. December 2, 1910.

patient complains of pain in right shoulder and knee, both of which are swollen and have regained somewhat the same appearance as before the injection. Temperature ranges from 98° to 99° F. The gummata at the right sternoclavicular junction and junction of the second costal cartilage and sternum are decreased in size, and no longer tender or painful. A tender, nodular growth, about 1½ inches in diameter, has developed at the inner edge and below the spine of the right scapula. Gumma on the ninth rib, at the anterior axillary line, has decreased in size and become soft. The upper end of the right tibia, on the inner aspect, is still tender, but much reduced in size. December 5, 1910.—All swellings have diminished to almost the normal dimensions. Patient remains up about the ward. General health and appearance much improved. (Figs. 1 and 2 illustrate Case I before and after injection.)

Case II.—Gives a history of a "sore" on the penis twenty-two years ago, for which he received no specific treatment. Has had pains in his limbs, increasing in severity at night, for ten years. About four months ago a small swelling appeared on the inner side of both thighs, adjoining the scrotum, which gradually increased in size for two months. These growths gave no subjective pain, but several weeks before admission of patient to the hospital they became ripe, raw and rough, sore to the touch, and gave forth a foul, light-colored exudate.

Fig. 3.—Case 2, condylomatous syphilide of groins before treatment.

Fig. 4.—Case 2, after treatment.

On his admission to the hospital, November 14, 1910, the growths are in the condition described above, about the size of the palm of the hand on both sides, fungating and condylomatous in appearance. Wassermann reaction negative. November 14, 1910, 0.5 gm. "606" injected into both buttocks by the writer. Four hours after injection, temperature 100.4° F., but soon after, normal again. Forty-eight hours after injection the patient is resting comfortably, and the edges of the condyloma are dry and scaly, showing some tendency toward healing. Eleven days after the injection the local condition is much improved, with marked healing and drying at the edges of the condyloma, but the centre remains moist. December 1 the patient's general condition is improved, and the local healing continues, although there is still a small, moist spot in the centre of each growth. December 5 the lesions have the appearance of being completely healed, leaving a darkened area covered with epithelium. (Figs. 3 and 4 illustrate Case II before and after injection.)

Case III.—November 14, 1910. Several small sores appeared on the penis eight years ago. The only secondary symptom was slight ulceration of the hard palate. Six years ago a small furuncle in the nose was followed by an acneform eruption of nose and cheeks, which has left a characteristic deep pitting of the involved area. The same year the patient went to Hot Springs for treatment. In 1905 he was treated with sixty soluble mercurial and about twelve salicylate of mercury injections. Between 1906 and 1908 his general health became bad. He lost weight and was unable to sleep because of severe frontal and occipital pains. He was not able to tolerate potassium iodid, and took protoiodid of mercury without improvement. Present condition—Complains of insomnia, due to a cephalgia of the frontal region, which is swollen and tender to touch over an area of about 5 cm. in diameter. Reflexes and vision normal. Right ankle and foot have been swollen for the past year. Urine negative. Wassermann test, positive. November 18, 1910, 0.5 gm. "606" injected into both buttocks by the writer. During the twenty-four hours following the injection, temperature does not rise above 99° F. Pains in the buttocks and down both legs, more marked on the left side. November 20, 1910, pain is less severe, although still present. Pains in head diminished. November 22, 1910 (four days after the administration of the "606"), his condition has improved markedly. Pains in head continue to subside. The swelling of right ankle has diminished in size. December 3, 1910, discharged. Swelling has disappeared from frontal eminence, and there is no longer any tenderness on pressure. He eats and sleeps well, and has improved in general health and spirits. He leaves for his home in the South, to return and report in six or eight weeks.

Case IV.—Admitted to Bellevue Hospital, November 25, 1910. Chancre developed September 26, 1910. Sore throat and a few sore spots in mouth appeared during September and October. October 24, 1910, a general eruption appeared, and the patient was given four injections of mercury salicylate in the buttocks. The chancre disappeared after the second, and the secondary rash after the third injection, but he complains of severe pains in the costal and lower vertebral regions. Before ad-

Fig. 5.—Case 5, gumma of tibia before treatment.

Fig. 6.—Case 5, after treatment .

mission to the hospital, Wassermann reaction positive. November 25, 1910. Wassermann reaction negative. Principal complaint—Nocturnal pains, more or less continuous by day, in the legs, chest and back. On this date "606," in dose of .5 gm., is injected into both buttocks. There is a slight reaction, with rising temperature, and complaint of pain in both buttocks, more severe on the right side, after injection. November 30, 1910 (five days after injection), the patient's general condition is much improved. Pains not so severe. The cervical and inguinal glands have become smaller, and the temperature is normal. December 3, 1910, patient's general condition improved, although there is still some slight pain and tenderness in both buttocks, and in the chest, while the back and leg pains have disappeared. Wassermann reaction positive.

Case V.—Entered the hospital November 15, 1910. Gives history of a "sore" in 1901. Had very little mercurial treatment, but has taken potassium iodid almost constantly since infection. Has had frequent sore throat, accompanied by ulcers of the mouth and tongue, and has suffered from pains in his joints. Now complains of pain over the inner end of right clavicle and in both elbows. November 10, 1910, he felt a dull pain in the right leg and noticed a swelling at the junction of the middle and upper thirds of the tibia. This gradually increased in size, was tender to pressure, and painful when he walked. Examination reveals a soft swelling here, fluctuating and red, with no induration of surrounding tissues. November 15, 1910, Wassermann reaction positive. November 25, 1910, "606" in dosage of 0.5 gr. is injected intramuscularly in the gluteal muscle on both sides. Temperature remains normal for the twenty-four hours following the injection, and the patient's general condition is good. He complains of slight pain at site of injection. November 27, pain has increased in severity, particularly over the right buttock and femur. There is some induration over the upper portion of right femur, posteriorly, and slight induration over the site of the injection in the buttocks. Heart examination reveals some irregularity. November 28, pain in right buttock and thigh greatly increased. Temperature has gradually risen from normal on November 26 to 102° F.

December 1, 1910 (six days after injection), pain is less severe, and exists only in right buttock and thigh. The irregularity of heart has subsided.

Fig. 7.—Case 6, syphilide of face before treatment.

Fig. 8.—Case 6, after treatment.

redness, swelling and softened area over right tibia have all disappeared. December 3, 1910, Wassermann reaction positive. (Figs. 5 and 6 illustrate Case V before and after injection.)

Case VI.—Patient contracted syphilis from her husband, May, 1907, when she had a miscarriage; and following that, she noticed a general eruption over her body. She was seen by the writer May, 1907, at which time she had papillo-squamous patches on both wrists, and some faded spots on chin. For the first year she was treated continuously, sometimes with a course of insoluble mercury to the full point of toleration; at others, with soluble mercurial injections (oxycyanid); and at others with internal medication. September, 1907, there were no symptoms. Treatment was continued for another year with practically no symptoms until June, 1909, when there was a return of the skin lesions, of the same character as before, upon the face, hands and arms. She received a course of insoluble, as well as soluble mercurials, hypodermatically, and was on several occasions completely prostrated by the mercurial injection, which affected her bowels, and caused mercurialization of the mouth. In spite of this treatment, supplemented by iodid of potash, patches have appeared with more or less persistence up to the present time. August 8, 1910—There are

Fig. 9.—Case 6, Palmer syphilide, before treatment.

two patches on the left wrist, two large areas on the hand, one on the right wrist, and one also on the back. The patches have persisted, with the addition of a patch on the right side of the face, involving the nose and upper lip, up to November 29, 1910, the time that the patient is given the injection of "606," .5 gm. of which is injected in two parts into both buttocks. Wasserman reaction positive. Reaction is intense. Patient suffers considerably for the first three or four days. Temperature elevation as high as 101° F. for the first forty-eight hours. Two days after the injection all the skin lesions begin to show evidence of disappearing. Five days after injection, comparison of the lesions upon the left hand with the photograph taken before injection shows a marked change for the better. The scaly surface is exfoliated, leaving the circular areas smooth and like the denuded surface of a burn, without any specific characteristic. The patch on the face has entirely cleared up, leaving simply a reddened area. Sixth day—Local pain greatly diminished. Patient cheerful and in excellent general condition. (Figs. 7, 8, 9, 10 illustrate Case VI before and after injection.)

Case VII.—November 29, 1910. Eight years ago chancre on the penis, followed by a swelling in the groin, which subsided without treatment. Secondary eruption on body and alopecia. Was given specific treatment for a short time. During the last three years both testicles have been swollen at intervals. The inflammation has always occurred spontaneously and disappeared without treatment. Ten weeks ago swelling appeared in both testicles, and they continued to enlarge to their present size. Examination finds both of them as hard as ebony, smooth upon the surface, somewhat irregular in contour, but not painful or tender to touch, and with no line of demarkation between the body of the testis and the epididymis. Measurements, De-

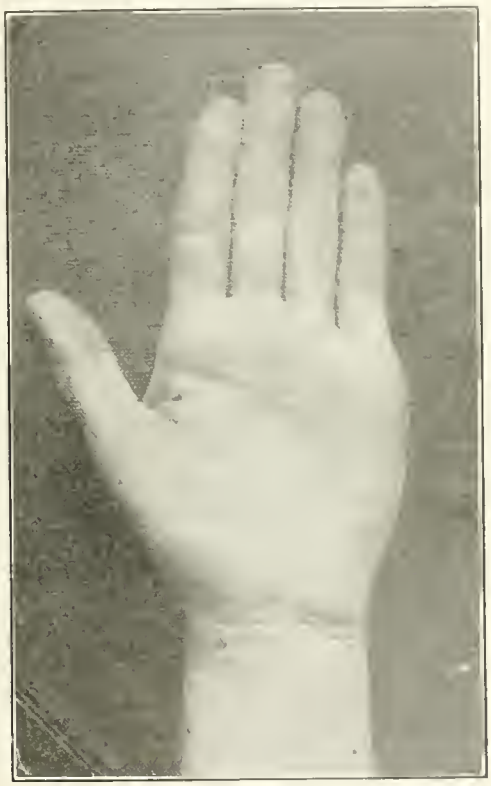

Fig. 10.—Case 6, after treatment.

cember 9, 1910: Transverse diameter, left, cm.; right, 18 cm. Length from upper to lower pole, left, 8.5 cm.; right, 7.5 cm.

At the time of admission the patient had a marked icterus, which disappeared after three weeks' time in the hospital, while the testicles have remained unchanged up to the date of injection. December 22, 1910, Wassermann reaction positive. December 23, 1910, .5 gm. injected in two equal parts into the gluteal regions. Pain intense for first forty-eight hours, and continues in lesser degree for greater part of a week, after which there remains only a soreness of buttocks. The measurements of the testes ten days after injection are: Transverse diameter, left, 14 cm.; right, 16 cm. Length from upper to lower pole, left, 7 cm.; right, 7 cm. The right testicle has assumed an almost normal condition. The epididymis is distinguishable apart from the body of the testis, and the left one is almost the

same. The previous hardness has totally disappeared, and both organs feel practically normal.

Case VIII.—Sore on penis in April, 1910, of nondescript character. In June of same year, was thought to have tuberculosis and sent to Fort Stanton. Developed a sore throat, and in August was given internal treatment in the form of protoiodid of mercury, under which his symptoms disappeared. A large ulcer of the fauces reappeared in the fall of 1910; also an ulcer upon the forearm. He was treated with injections of salicylate of mercury, under which the sore upon the forearm disappeared, but the ulcer in the throat did not yield. A Wassermann reaction under treatment was negative. Treatment was discontinued for a period of two months, when another Wassermann reaction was taken, which was positive. December 24, 1910, 0.55 gm. of "606" injected by the writer in equal parts in each buttock. At this time the ulceration appeared as is shown in Fig. 2. Immediately following the injection there is some reaction in the

Fig. 11.—Radiograph of syphilitic osteitis.

nature of sharp local pain. December 25, 1910, local pain slight. Temperature, 100.4° F. No apparent change in the lesion. December 27, some muscular pain in limbs, and nausea. Temperature, 101.8° F. First apparent change in the lesion, which is filling in from the bottom. December 28, 1910, pain in buttocks at its maximum, requiring hypodermic of morphine. December 29, temperature, 99.3° F.; lesion healing. December 31, ulceration entirely healed; patient feeling well, except for local tenderness. January 2, 1911, patient resumes work: slight tenderness at site of injection.

In addition to these eight cases, reported in detail, there have been four others which have received the salvasan injection hypodermically, and these have followed more or less the same course as the previous ones already described. These cases consisted of an early general secondary syphilide of the skin, a tertiary bone syphilis (Fig. 11), secondary syphilitic ulceration and necrosis of the lower extremities, and a case with no outward evidence of the disease, clinically, but a promptly positive Wassermann reaction and an inordinate desire to receive the "606" injection.

The last sixteen cases, *completing a total of twenty-eight in all,* have a special interest on account of the fact that they have been given the remedy by intravenous injection, and the freedom from pain and other reaction, with the exception of nausea and vomiting, has been a noteworthy feature in these sixteen cases, as has also been the even more prompt favorable action upon the symptoms than was experienced by the hypodermic method.

These cases were: Seven cases of general syphilitic eruption, one of which presented a specific iritis; three cases of syphilitic ulceration of the fauces, one necrosis of skull, one primary lesion, and four cases with no present symptoms. In one of the cases the eruption faded away almost completely in sixteen hours, and in the others there was marked disappearance in forty-eight hours, and prompt improvement in the coexistent iritis.

All the cases with ulceration in the fauces responded actively to the Ehrlich treatment. There is, twenty-four hours after the intravenous injection, already an evidence of drying up of the circumference of the sore and softening of the induration in the same area, in the case with the primary lesion. This patient had had no previous treatment. *Spirochetæ pallidæ* were found in the serum from the lesion and the blood reaction had yielded a positive Wassermann, as it had in all of the other additional cases with one exception.

There is little question as to the great importance of this almost sensational contribution to medical progress; yet in weighing its importance we must await the latest reports, and the probable inconsistencies and vagaries that always follow the too dogmatic claims of a new discovery. The overzealous enthusiasts tend rather to do harm than to help the successful investigator, and the hard-headed skeptic is the counterbalance, though the other extreme.

It seemed to me at the time of my first report upon this subject, December 5, 1910, that the treatment would prove to be more an adjunct to the older method than one likely to supersede it; and the latest reports show that other investigators are inclined to the same opinion. I am personally impressed with the fact that its utility is not confined to any one stage of the disease, but that striking results occur in all stages. There seems to be no contraindication to the preliminary use of the usual specific remedies, so far as affecting the potency of the result of the injection is concerned; and there is ample reason to believe that in a large percentage of the cases the subsequent recourse to such medications will be required.

The intravenous injection is by far the most satisfactory means of conducting the treatment, not only because of the freedom from pain and prompt action, but also on account of its simplicity. The technique employed is that followed in obtaining the blood for a Wassermann reaction, a needle, and not a canula, being forcer into the lumen of the vein, which is removed afterward without ligature or stitch. The bulk of fluid is 400 c.c. of normal salt solution, to which enough 2 per cent. iodine hydroxide is added to neutralize the acidity of the salvarsan. This makes a satisfactory solution, which is perfectly transparent.

In this particular series of twenty-eight cases, it is

necessary to watch the ultimate developments before deriving conclusions as to final results. It must be acknowledged, however, that the immediate results were remarkably favorable, and have remained so over three months in some of the cases.

That we have reached the Utopian era in the discovery of a new specific for syphilis that will displace the older remedies of hundreds of years—a panacea that will work overnight—is not to be thought of seriously. But if it continues to demonstrate its prompt action in malignant conditions of syphilis, to be of value in cases that relapse in spite of the continual use of the older remedies; in short, to be a supplemental means of treatment that will render the system more amenable to the action of the common form of medication by effecting even a partial attenuation of the virulence of the disease, it must indeed prove of great importance in the management and extinction of this dread malady.

25 Park Avenue.

A SIMPLE METHOD FOR THE RELIEF OF CERTAIN FORMS OF ODYNPHAGIA.*

By P. TETENS HALD, M.D.,

COPENHAGEN, DENMARK,

PRIVATDOCENT IN THE UNIVERSITY OF COPENHAGEN; ASSISTANT SURGEON EAR AND THROAT DEPARTMENT OF THE KOMMUNE-HOSPITAL, COPENHAGEN.

At a meeting in June, 1910, of the Laryngological Section of the Royal Society of Medicine in London Mr. Mark Hovell stated during a discussion on the treatment of odynphagia in tuberculous laryngitis by injection of alcohol into the superior laryngeal nerve that he had found firm pressure of the flat of the hands, applied to the ears during swallowing, relieved the pain of sore throat. This observation Drs. Milligan and Jobson Horne confirmed by saying that they had found Mr. Hovell's method to be very useful.[1]

The scope of this paper is to render an account of the researches which the observation of Mark Hovell led me to undertake, and also to try to give an explanation of the effects observed. The clinical material consists of forty-six cases of inflammatory diseases of the tonsils and their surroundings, for a great part treated in the ear and throat department of the Kommunehospital in Copenhagen, to the director of which institution, Prof. Holger Mygind, I am obliged for the clinical facilities afforded me.

It proved feasible in thirty-two out of the forty-six patients considerably to relieve and not rarely completely to cause the cessation of the present odynphagia by one of the two following procedures, both of which I comprise under the denomination: the compression method.

1. By exercising a firm pressure against the tragus (in the following, mentioned as "tragus pressure").

2. By exercising firm pressure against the upper part of the mastoid, close to the insertion of the pinna (in the following, mentioned as "mastoid pressure").

In most of the cases the tragus pressure turned out to be the most efficient. Not infrequently both procedures appeared equally relieving. Only in a very few cases mastoid pressure alone was efficient, when tragus pressure proved of no avail.

Examination of patients suffering from unilateral affections (twelve cases of peritonsillar abscess) showed that, while pressure exercised against the contralateral side had only small, or no, effect, pressure on the ipsolateral side caused considerable relief, but the best result was obtained by employing the compression method on both sides simultaneously.

In order to exercise a pressure lasting for some time—say, during a whole meal—I have constructed a pressure apparatus (Fig. 1) which may be worn by the patient without disturbance in the ingestion of food. It is simple, cheap, and very efficient. The construction is easily understood from the picture. The branch *a* is firmly connected with the transverse bar *b*, on which the movable branch *c* slides. To use the apparatus apply the caoutchouc pads at the distal end of *a* and *c* against the two tragi, letting *c* slide in the direction of *a* as far as the diameter of the head will allow. The apparatus then should

Fig. 1.—Apparatus for making tragus compression.

keep in place of itself, and turning the screws will bring about any amount of pressure desired. (The screws are not firmly connected with the pads, but move freely in them, as in sockets, so that the region of skin under pressure is not ruffled when the screws are turning.)

If some one in the surroundings of the patient is willing to exert the pressure with his fingers this is, of course, equally efficient, but may prove a little wearying to the fingers during a meal of some duration.

The compression method is not without some inconvenience to the patient, but in my experience the slight annoyance caused by the pressure has been by far preferable to the often very disagreeable odynphagia.

Thus much for the facts. As to the explanation of the effect observed, the first thought, when dis-

*Paper read in the Medical Society of Copenhagen, December 6, 1910.

cussing the relief of pain by agents of the kind in question, might not unnaturally be that our old and honored ally, viz., suggestion, had once more helped us and suffering humanity. In my opinion, however, suggestion has not much to do with the efficiency of the compression method. All the patients have first been tried by the exertion of pressure simultaneously against the forehead and the occiput, and no one has experienced any relief from this manner of compression. Further of the different points in the vicinity of the ear examined only the tragus and the mastoid region described have proved to be of importance as points for pressure.

If now the efficiency of the compression method is not due to suggestion, it is necessary in order to find a probable explanation to analyze the manner of action as far as possible, and first of all to determine the exact situation of the skin area or areas, the compression of which causes the relief. This is not feasible when following implicitly the method described by Mark Hovell, and this is the reason why I began my researches which led to the finding of the efficiency of tragus pressure and mastoid pressure, both of which procedures are characterized by exertion of the pressure against a circumscribed area in the vicinity of the ear opening.

When considering the tragus pressure the question arises whether its efficiency is due to an (indirect) pressure against the tympanic membrane caused by compression of the air column contained in the external meatus. This question was solved by exertion of tragus pressure subsequent to the introduction in both meati of a glass tube open in both ends, when it was found that tragus pressure even now relieved the present odynphagia—being, of course, at the same time, more disagreeable to the patient. Tympanic membrane and middle ear would thus appear to be without importance for the action of tragus pressure. As I shall show further on, the compression of the tragus itself is probably equally unimportant for the effect of tragus pressure, which then only can be due to the compression of the skin of the posterior meatal wall.

It would seem a fair statement that my researches have shown that firm pressure against two distinct skin areas in the vicinity of the external ear opening may relieve or cause the cessation of certain forms of odynphagia. The explanation of this fact may in my opinion be found in Head's admirable work[2] on disturbances of sensation, with especial reference to the pain of visceral disease, the pressure acting as a counterirritant on that skin area which, according to Head, may present hyperalgesia in diseases of the tonsil.

As a result of very painstaking and extensive investigations, Head has mapped out a whole series of areas on the body surface, which may become hyperalgetic in visceral disease. The different areas are to a certain degree characteristic of diseases in different visceral organs and contain one or more "maximum spots" of definite location in each area. These maximum spots are particularly hyperalgetic, and pain is often referred to them, when there is an affection of that visceral organ which stands in relation to the given area. To understand the fact that pain in visceral disease may thus be referred to certain skin areas we must suppose that a sensory disturbance passes up the nerve fibers from the viscera to set up changes in the activity of that segment of the spinal cord in which they terminate; and that these disturbances of activity are referred to that portion of the skin which is supplied by the affected segment.[3] As to the occurrence of tender skin areas in consequence of visceral disease, Head has rendered it highly probable that if any segment of the cord is disturbed by painful stimuli from an internal organ a stimulus applied to the skin over the areas supplied by the nerve roots belonging to this segment will be exaggerated, because the sensory impulse arising from this second stimulus does not fall into a normal and quiescent cord, but into one whose activity is already disturbed. Thus a stimulus which normally was perhaps only uncomfortable would now appear to be very painful.[4]

Without going further into these interesting and plausible explanations, I wish to emphasize with Sahli[5] that Head has by his investigations contributed very much to a clearer understanding of the manner in which therapeutically employed skin irritations relieve pain caused by visceral disease, in so far as it seems a probable hypothesis that the same anatomical tracts which give rise to the skin hyperalgesia in visceral disease may contrariwise serve in conducting pain-relieving impulses arising from irritation of the corresponding skin area.

Also in affections of the tonsils Head has been able to map out a characteristic hyperalgetic area, the hyoid area.[6] Posteriorly it runs up on to the mastoid, and hence superficial tenderness over this area may give rise to fictitious mastoid tenderness. The lobule of the ear is also tender. The anterior border of this area lies in front of the lobule, but does not include the tragus. When this area is affected the meatus, especially the posterior portion, is intensely tender, and the insertion of an aural speculum will give much pain. The maximum spot of this area on the surface of the head lies just behind and below the angle of the lower jaw. A second most important maximum lies in the external auditory meatus. The following picture reproduced from Head's work illustrates the limits of the area in a case of destruction of the left tonsil from malignant disease.[7]

Fig. 2.—Hyperalgetic area in cancer of the tonsil.

As it was rather late in my researches that I came across Head's very full description of the hyoid area, I have tried to trace the area in only thirteen of my patients and I have not been able to find it in more than four of these. As for the maximum spots, these have not appeared to me to be particularly tender. Now it is well known that the hyperalgesia of the corresponding skin area is present only in a fraction of the cases of visceral disease. Thus Faber[8] in his investigation on 200 cases of intestinal disease found it in only 15 per cent., while Würtzen[9] was able to demonstrate it in 44 per cent. of his series of 376 patients suffering from pulmonary tuberculosis. And Wilamowski[10] has stated that hypalgesia may be present in the areas in which hyperalgesia is usually found in consequence of visceral disease.

I therefore maintain my hypothesis, viz., that the efficiency of the compression method regarding odynphagia in diseases of the tonsils and their surroundings is due to the circumstance that it causes a strong counterirritation on a skin area whose sensitive (pain) nerve supply stands in intimate central relation to the sensitive (sympathetic) nerve supply of the diseased tonsil.

To make this contention acceptable it seems necessary to prove in some way that there is a certain probability of the real existence of the supposed intimate relation between the sensitive nerves supplying the two regions in question. Now, Head has already drawn attention to the fact that these regions in fetal life develop from tissues of immediate vicinity, thus suggesting a close vicinity also of their nervous supply.[11] The hyoid skin area of Head develops from the external surface of the second cephalic visceral arch. A segment of the inner surface of this same arch develops into the anterior palatine arch, while the tonsil itself is formed from tissues in that internal visceral cleft which forms the posterior limit of the second cephalic visceral arch (Disse [12]).

A further support of my contention is, in my opinion, to be found in the following results of my clinical investigations. As mentioned above, I have found tragus pressure the most efficient component of the compression method. I have further been able to show that indirect pressure against the tympanic membrane played no rôle in the efficiency of tragus pressure. Finally it turned out in those cases (till now nine) which I examined on this point that compression of the tragus alone between the fingers failed to give relief, though "tragus pressure" in the same cases proved very effective. Therefore it seems highly probable that the skin area from which the pain relieving impulses arise in tragus pressure is limited to the lateral portion of the posterior meatal wall, *i.e.* one of the maximum spots of Head's hyoid area. That compression of the tragus alone was unable to give relief supports also my explanation, as the tragus develops from the first, and not from the second (hyoid), cephalic visceral arch. But I am bound to state at the same time that up to the present I have never been able to relieve odynphagia in tonsil affections by pinching the skin corresponding to the second maximum spot described by Head in the hyoid area, viz., behind and below the angle of the lower jaw.

As to mostoidal pressure, the region on which the pressure is exerted does not represent a maximum spot according to Head—which is perhaps the reason why mastoidal pressure appears less efficient than tragus pressure—but it forms at least a part of Head's hyoid area.

Whether now my explanation of the efficiency of the compression method be correct or not, I think I am justified in recommending its trial in the mentioned affections.* Presumably the method will also in the hands of my colleagues bring relief and facilitate ingestion of food in not a few cases. And this is in my opinion the essential point.

*I have tried the method also in cases of odynphagia from tuberculous laryngitis and esophageal diseases, but as yet in too few cases to allow of any statement as to its efficiency in these cases.

A CASE OF ANEURYSM OF THE HEART.

By JOSEPH B. BETTS, M.D.,

BUFFALO, N. Y.

ASSISTANT PHYSICIAN, BUFFALO STATE HOSPITAL.

Although aneurysm of the heart is not extremely rare, comparatively few cases have been recorded in the general medical literature of this country. Warthin* has collected from various sources reports of over 300 cases.

According to him the condition may be either congenital or acquired. The former, due to defective development, is seldom found later than in infancy, as individuals with this defect rarely attain adult life. The acquired form may be either acute or chronic—the acute form due to localized areas of necrosis from infarction or from septic myocarditis. The chronic form is caused by degeneration of the myocardium from syphilis of the heart muscle itself or more commonly following obstruction of the coronary artery by atheroma or syphilitic sclerosis. The left coronary is usually selected, the aneurysm consequently affecting the left ventricle near the apex, and as a rule the pericardium is adherent to the aneurysm wall.

The following is the report of a case recently examined, *post mortem*, by the writer:

D. D., male, aged seventy-two years. Laborer, born in Ireland. Was admitted to the Buffalo State Hospital June 17, 1891, from the penitentiary where he had been committed for drunkenness. He showed the usual symptoms of alcoholic hallucinosis with apprehensiveness and violent tendencies. This was followed by marked mental deterioration, in which he subsequently lived a quiet vegetative life until January, 1910, when he suffered from retention of urine, due to prostatic hypertrophy. He required catheterization and was confined to bed on account of increasing general weakness and extreme general arteriosclerosis. There were no symptoms to call attention to the heart except those associated with general arteriosclerosis. September 10, 1910, he was still confined to bed, showing no acute symptoms, but he occasionally complained of unlocalized pain in the thorax. On the morning of September 30, 1910, he was noticed to be in a much weaker condition, with a temperature of 98.2° F. Respiration 36. The pulse was so weak and irregular that it could not be counted. At noon of the same day there was a sudden collapse, in which he died.

Abstract of Autopsy.—Two and three-quarter hours *post mortem*. Body of an aged man somewhat emaciated and showing slight edema of the subcutaneous tissue generally. No scars or other signs of syphilis. Head: Skull not noteworthy. Dura firmly adherent to calvarium. Cerebrospinal fluid clear, but somewhat increased in amount. Brain, 1100 grams. Marked general atrophy of the convolutions and nodose atheroma of the carotid arteries and their branches. Thorax: Left pleura

*Reference Handbook of the Medical Sciences, Vol. IV, page 580.

free from adhesions. The left lung, 385 grams. Emphysematous. Right pleura firmly adherent throughout so that the right lung could not be removed entire. Section of lung shows edema and unresolved pneumonia. The bronchioles are dilated and much hypertrophied. Heart: 640 grams. Hypertrophy and dilatation of all the chambers. At the apex is a large aneurysmal dilatation in the wall of the left ventricle, to which the pericardium is firmly adherent over a surface of 12 c.m. in diameter (Fig. 1). The wall of the pouch is translucent and measures in its thinnest portions 2 mm. in thickness. Mainly the aneurysm is filled with fluid blood, but at its periphery there is a thin adherent organized thrombus. Both auriculoventricular valves are widely dilated and incompe-

Fig. 1.—From a photograph of the heart; posterior surface. Note the thickened tortuous coronary artery. The pericardium adherent to the aneurysm has been turned back to the left.

tent, but show no sign of old or recent valvulitis. The aortic and pulmonary valves are competent. The endocardium of the left ventricle is opaque and appears fibrous. The right coronary artery is not noteworthy, but the left is thick-walled, calcareous and tortuous. On transverse section the vessel is 3 mm. in diameter, and its lumen is practically obliterated by atheromatous changes (Fig. 2).

The heart muscle shows little interstitial increase except near the border of the aneurysmal sac. The following measurements of the heart were made: Length of heart from base to tip of aneurysm, 17 cm.; average thickness of wall of the left ventricle, 2 cm.; circumference of aneurysm at its junction with left ventricle, 26 cm. Long diameter of aneurysm, 10½ cm.; short diameter, 7 cm.

The aorta shows little atheroma at its origin, but below it shows extreme calcareous atheroma, the process continuing into the iliacs as far as they can be traced. Abdomen: Spleen, 100 grams. Arteriosclerotic. Liver, 1355 grams. Shows a patch of old perihepatitis on the upper surface of right

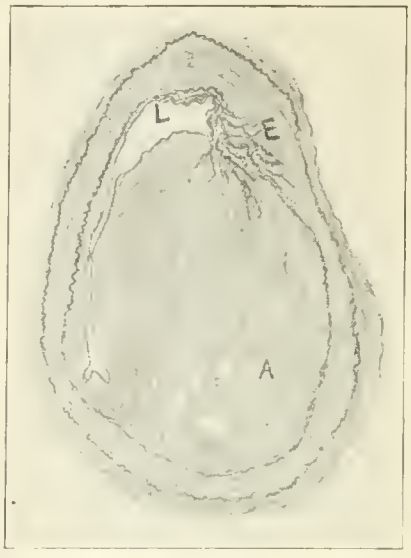

Fig. 2.—Section through the left coronary artery. L, lumen; E, split internal elastica; A, atheromatous nodule. Weigert's elastica stain; Leitz, obj. 2, Oc. 1 (30x).

lobe. On section moderate passive congestion. Gall bladder and ducts negative. The pancreas shows marked fatty change. Adrenals not noteworthy. Gastrointestinal tract negative. Prostate hypertrophied; urinary bladder, ureters and pelvis of kidneys distended with urine. The kidneys together weigh 320 grams. They are both swollen and pale. Each pelvis dilated, but free from pus. The capsule of each is firmly adherent to the cortex and perinephritic fat. Vessels prominent on section. Cortices pale and swollen.

Fig. 3.—Branch of the left coronary artery at the junction of the aneurysm and left ventricle. Weigert elastica stain. Leitz, obj. 7, Oc. 1 (370x).

Microscopical Notes.—Cerebral cortex shows moderate fibrosis of vessels. In the cerebellar cortex is a small wedge of arteriosclerotic softening. Heart: Sections from the upper left ventricle show little interstitial increase. The muscle fibers appear to be slightly hypertrophied, but are not excessively

pigmented and the striations are well preserved. The left coronary is almost completely occluded, showing merely a slit-like lumen pushed to one side by a large atheromatous nodule. The internal elastica is split up and the fibrillæ radiate from the edge of the lumen for a short distance into the atheromatous node (Fig. 2).

There seems to be no evidence that the arterial disease is syphilitic in origin. Sections including the left ventricle wall and aneurysm pouch show that, proceeding downward, the muscle becomes more and more invaded by new fibrous tissue until reaching the wall of the sac where the muscle fibers are entirely replaced by fibrous tissue. A small branch of the coronary found at the junction of the left ventricle wall and aneurysm shows much thickened walls and a bead-like breaking up of the internal elastica, which is thrown into large folds. The lumen of the vessel is much narrowed and contains only a few blood cells (Fig. 3).

In the thinner portion of the aneurysm wall, with adherent pericardium, the muscle fibers have entirely disappeared. The fibrous tissue just beneath the pericardium is fairly vascular, its vessels apparently derived from the adherent pericardium. In the deeper layer the wall is much less vascular and the fibrous tissue somewhat hyaline. The right lung shows unresolved pneumonia and bronchiectasis. Kidney sections show the usual picture of subacute interstitial nephritis, with widely dilated tubules and extreme arteriosclerosis.

This case is obviously one of the chronic type, due to a narrowing of the left coronary artery by atheromatous changes. The extreme general arteriosclerosis no doubt aided in stretching the weakened heart wall by obstructing the blood stream. No signs of syphilis were found anywhere, and the type of arteriosclerosis appears to be non-syphilitic.

This case shows the usual characteristics of cardiac aneurysm, viz., the site of the defect, the general arteriosclerosis with coronary obstruction and the adherent pericardium. As is usual in these cases, the diagnosis was made *post mortem*.

STOCK VACCINES IN ACUTE GONORRHEA.

By FRANK A. PALMER, M.D.,

MORRIS, ILL.

The use of the stock vaccines in combating various infections is of special interest to the practising physician, the difficulties of determining the opsonic index in the use of the autogenous vaccines being too time robbing and too intricate in technique to permit of its being done as a routine in the office.

The use of stock vaccines in gonorrhea has met with quite general acceptance, but only in the gleets and other chronic conditions. Reports upon its use in acute conditions have been, up to the present date, uniformly unfavorable. As our experience has been at variance with that of others in the treatment of acute gonorrhea, it is thought that a review of our cases and technique may be of interest. We believe that the difference in the results obtained is due to the fact that we have used much more minute doses than have been reported elsewhere in the accessible literature. Alice Hamilton alone used doses as small as ours, but as her work was done on the vaginitis of little girls, the doses were relatively much larger. We have treated in all about 50 cases of acute gonorrhea with the vaccine, in a period extending over two years, with results which have varied somewhat with the technique employed, but with results which speak strongly in favor of its use in these conditions.

In our earlier cases we were inclined to use doses which we now consider to have been much too large, although they were smaller than those usually recommended. At first we gave for the first injection five minims of a vaccine containing fifty million of the bacteria to the cubic centimeter. This was usually followed by a slight reaction and an increase of the discharge, succeeded in a day or two by a marked decrease in the discharge. This usually diminished to a few drops of a thin watery secretion. These few drops, however, then proved to be nearly as hard to overcome as the traditional morning drop of gleet, by the technique which we were using, which consisted in increasing the doses of the subsequent injections as rapidly as possible without producing a reaction, up to a dose of 1 c.c. Individual cases received 2, 3, and 4 c.c. doses at the latter end of their treatments. The course which the cases ran under such treatment is well illustrated by the following:

Case I.—A. M., male, aged 24, had a fresh infection, profuse discharge containing gonococci, intra and extracellular. He received a first injection of 5 minims of a fifty million vaccine. There was a light reaction, succeeded by a diminution of the discharge by the time for the next injection to a drop or two a day of a thin watery secretion. A second injection of 8 minims was given five days later. Injections were given twice a week from now on, with little change in the discharge. The doses were rapidly increased to 1 c.c., and the interval increased to one week. The discharge ceased entirely at the end of five weeks.

Case II.—M. M., aged 26, male. I was in doubt whether he had a fresh infection or an acute exacerbation. Slides from the profuse discharge showed a pure culture of gonococci. Under treatment for six months, he was given at first 10 minims of fifty million once a week. After the first dose there was a decided reaction with subsequent diminution of discharge to a few drops of watery discharge a day. Injections were continued with gradual increase of amount up to 3 c.c., with no further decrease in discharge. The injections were finally stopped and the discharge ceased within two weeks of last injection.

The doses in these cases were much too large. In the latter case a negative phase was, undoubtedly, maintained by the too frequent and too large injections. After the injections were stopped a positive phase was established and the discharge promptly ceased. Such experiences led us to further reduce the dose and our results became surprisingly better. We are now using 2 minims of the fifty million, with a one week interval, and not raising the dose except in occasional cases, and then only when we have become satisfied that recovery is not to be obtained without such increase. The danger of giving too large doses is much greater than the danger of giving too small. No reaction should be produced at any time. The following cases illustrate the method now pursued and the results obtained.

Case III.—A brewery employee, aged 35, drinking about 4 gallons of beer a day; had a fresh infection and a profuse discharge. Slides showed a pure culture of gonococci. He received a first in-

jection of 3 minims of a vaccine containing twenty-five million of the killed gonococci to the cubic centimeter. He was given in all three such injections. After the first one there was no reaction. Three days later there was a drop of watery discharge. At the time of the third injection there was no discharge. There was no recurrence. His daily consumption of beer was not interrupted during the treatment.

Case IV.—G. C., male, aged 23, had a fresh infection, with a moderately profuse discharge containing gonococci. He received 2 minims of the fifty million vaccine once in five days. After four injections he refused further treatment, as all discharge had disappeared. There was no recurrence.

All cases do not respond quite as brilliantly, of course, but the majority of them do. We have had but one case which we did not succeed in freeing from his discharge, and this is the only one since we started using the minute doses who was not freed from his discharge within three weeks. Strangely enough, we were absolutely unable to influence this case at all with the vaccine, and he was running as merrily and as profusely when he disgustedly deserted us at the end of four weeks as he had been when he first came to us shortly after the infection.

Some of the most gratifying results were obtained in gonorrheal pyosalpinx, both in the acute cases and in the acute exacerbations. Of these we have had four cases. All four withdrew themselves from treatment before the anatomical findings were entirely normal because they were satisfied with their improvement. Our results, therefore, can be regarded as only symptomatic cures. Even this was very gratifying to us as all of them were cases which would have demanded a hysterectomy previous to the use of the vaccines. The following is a representative case.

Case V.—J. C., aged 25 years, had been within a few weeks discharged from another hospital where she had been under treatment for an acute exacerbation of her pus tubes, and to which she expected to return for a hysterectomy. Now she had another exacerbation, a large tender mass filling the cul-de-sac, an area of softening on the left side, pain, vaginal and abdominal tenderness, moderate fever, and moderate vaginal discharge; she was confined to bed. Slides from the vaginal discharge showed gonococci. Four minim injections of the fifty million vaccine were given every other day. She left the hospital at the end of a week. Injections were continued twice a week at the office for three weeks. She refused further treatment as she considered herself well. The tubes are two small hard strings. Leucorrhea is small in amount and shows no gonococci.

Two cases of gonorrheal rheumatism gave us very gratifying results, the relief of pain being prompt and the cases recovering promptly without stiff joints.

Case VI.—G. W., male, 45 years, was confined to bed with pain in both ankles and one hip. He has been having gonorrheal discharge from the urethra for some weeks, which has disappeared since joints were inflamed. Both ankles were considerably swollen and painful on motion. The hip was also very painful on movement although no swelling could be detected. The injection of 2 minims of the twenty-five million vaccine was given twice a week, in all eight injections. There was complete recovery and perfect function of the joints.

Case VII.—A prostitute, with right wrist and left elbow involved, and a vaginal discharge containing gonococci. She was given five injections of 2 minims of the twenty-five million vaccine. Relief of pain followed after the first injection, with complete recovery with perfect joints.

We have also to report one case of gonorrheal conjunctivitis. Here in addition to the vaccine a solution of protargol was used.

Case VIII.—A young lady came to us with an inflamed conjunctiva which had developed the day before. As there was considerable of the ordinary epidemic conjunctivitis in the neighborhood, and one case in the family, a simple eyewash of boric acid and camphor water was given her. Two days later she reported that the eyes were much worse and that the photophobia was severe, confining her to the house. An examination showed an intensely inflamed conjunctiva with a copious discharge, which showed gonococci in smears. She was given two injections of two minims each of the fifty million vaccine, and a solution of protargol was used locally. The second injection was given under protest, as the improvement after the first was so prompt and complete that on the third day thereafter she went back to her work in a store. The recovery was complete and perfect. There were no gonococci present in the vaginal secretions of this young lady.

A few words may be in order in regard to the technique of the injections. We have used the all-glass Luer syringes for this purpose. It is also our custom to obtain the vaccine in little glass bottles or vials with rubber corks. The vaccine is abstracted from the bottles by pushing the needle through the rubber cork and withdrawing the quantity desired without removing the cork from the bottle. A little air must sometimes be injected into the bottle before the withdrawal of the vaccine can be accomplished. This procedure maintains the portion of the vaccine not used in a sterile condition, and considerably reduces the cost of the treatments. The injections are made into the gluteal muscles, and it has been our custom to insert the needle perpendicularly to the skin as in intramuscular injections. While we realize that the number of cases reported is too small to give one a basis for the determination of the ultimate value of the use of the vaccine in acute gonorrheal conditions, yet the number is sufficient to render the results striking, and we hope that it may prove as valuable in other hands as it has been so far in ours.

GASTRIC ULCER, HEMORRHAGE, OPERATION, GENERAL PERITONITIS, VACCINE THERAPY.

By J. RUSSELL VERBRYCKE, Jr., M.D.,

WASHINGTON, D. C.

I report the following case as being one of the severest cases of illness that I have ever seen recover. Her return to perfect health after a general peritonitis was undoubtedly due to the employment of autogenous vaccine therapy.

Mrs. L. S., age twenty-four, married eight years, came under my treatment July 6, 1910. Family history, negative. Past history, unimportant save for an anemia due to a profuse menstruation of one week's duration. Has had considerable trouble with her stomach for some years, which she calls gastritis. Present illness: All spring has had some distress in the stomach after eating. Has been

afraid to eat much. Three days before, July 3, had vertigo and almost fainted. Her heart seemed to beat slowly and feebly. The next day had tachycardia for some hours. Complained also of gas in the stomach, some nausea but no vomiting, and no great amount of pain. Physical examination showed a moderately tender spot in the epigastrium and at the left of the spine. Strong benzidine reaction for occult blood. Thread impregnation test was positive showing an ulcer on the lesser curvature 5 cm. from the pylorus.

The patient was put to bed for three weeks on a modified Von Leuble treatment. She improved considerably and blood disappeared from the stool, but after going home and gradually getting around all symptoms returned. As she could not afford to take an extended course of medical treatment, operation was advised and accepted. August 5, 1910, gastroenterostomy was performed by Dr. Thomas Kelly. A small ulcer was found, as diagnosed by the thread, 5 cm. from the pylorus. Patient was returned from the operating room in good condition and did well until 4:30 the next morning, when she vomited seven ounces of bloody fluid. At 8 A. M. she vomited seven more ounces. Her pulse had risen from 80 to 126, respiration was 28, temperature 97.4°. She vomited several more times before 1:30 P. M., when she filled a pus basin with pure blood and clots. In all she probably lost about a quart or more of blood and her pulse went progressively up to 190 with a slight amount of air hunger. At 2 o'clock she was taken to the operating room again and under nitrous oxide oxygen anesthesia, during which she once stopped breathing, necessitating forced oxygen, an incision was made in the stomach wall and the gastroenterostomy opening turned out through this incision and an extra line of sutures taken. Murphy salt solution was started. She hiccoughed up bloody fluid a mouthful at a time for the next three days. Hemoglobin was 40 per cent. August 9, 1910 (four days after operation), tympanites began to be troublesome, becoming more marked on August 10, when liver dullness was almost obliterated. There was some abdominal pain and slight nausea, and she vomited some bile. Temperature became irregular, ranging from a little above normal in the morning to 102° in the evening. The Fowler position was ordered. August 11 a profuse discharge was noticed coming from wound. A rather obstinate diarrhea started at this time which persisted for some days. Benzidine test still continued positive. For the next week symptoms were profuse discharge, gapping of the wound, exposing the stomach wall over an area of about three inches, abdominal tenderness, gas, diarrhea, and great weakness and wasting away from the flow of pus and toxemia. August 22 the above symptoms continued more or less, although patient's condition improved slightly under forced feeding so that she could sit for an hour or so in the wheel chair. Examination on the 22d showed a swelling in the lower abdomen like a distended bladder. This was proved by percussion to be gas over fluid and a secondary abscess was diagnosed. But, when opened through a suprapubic incision, a quart of foul smelling pus was evacuated, not from an abscess, but from the general peritoneal cavity. Not an adhesion was visible anywhere. The finger could easily be introduced directly into the peritoneal cavity from either upper or lower wound and the intestines everywhere were bathed in pus. After the pus was evacuated the temperature dropped in the evening from 102 to 100. Also considerable relief was obtained from pain and distention, but for the next week both wounds drained profusely, between three quarters and one pint a day, with no tendency to abate in spite of Murphy salt solution and the Fowler position. On August 31 I decided to try autogenous vaccine therapy and called in Dr. John Neate of the Army Medical School, who took cultures which showed two strains of streptococci, staphylococcus, colon bacillus, and a negligible number of *Bacillus pyocyaneus*. An autogenous vaccine was made and on September 2 the patient received her first injection of 50,000,000 streptococci. No reaction followed either locally or generally and the next day 100,000,000 were given. A slightly higher range of temperature was noticed than for the two days preceding the injections. On Septembr 5 150,000,000 streptococci and on September 7 200,000,000 streptococci were administered. Quite a reaction followed the last injection, pain locally and malaise generally. The discharge, however, did not lessen perceptibly nor the subjective symptoms improve. The next day 250,000,000 staphylococci were given and after a rest of a day 500,000,000. After this the patient felt much better and the discharge, though profuse, was thicker and not so offensive. September 11 treatment with the colon bacilli was started with 100,000,000 and the next day quite an improvement was noticed. Discharge from the lower wound almost completely stopped and from the upper wound was much less though still profuse. Appetite, which had been completely absent, began to improve and the patient looked much better. Her temperature, which began to drop after the third injection of streptococci, did not go above normal after this date. September 13 500,000,000 staphylococci were given. Hemoglobin was read at 56 per cent. (Dare), an improvement of sixteen points. The drainage was not over an ounce. From this time the improvement was more like a miracle than anything else. September 15 200,000,000 colon bacilli were given. The discharge for twenty-four hours was not over two drams and patient was better and stronger in every way. In a little over a week more the discharge had absolutely stopped. The lower wound had completely healed and the upper had diminished in size from three inches to the size of a quarter of a dollar. The edges were then freshened and brought together with silkworm gut, but on account of tension did not heal by first intention. One more injection each of staphylococci and colon bacilli were given to keep up resistance. After an absence from the city of five weeks I did not again see the patient until November 10, when both wounds had completely healed as if by primary union. She had gained twenty pounds and her stomach was apparently normal. She felt better than she had in years and no hernia had developed in spite of the previous gaping wound.

I feel that had it not been for the vaccine therapy her recovery, even if possible, would have been postponed indefinitely, as hope for her recovery had been given up by several who saw the case with me, and that she would still have been more or less of an invalid, instead of to-day, only three months after a general peritonitis, doing work about the house. This method of treatment will no doubt prove a valuable addition to the Murphy salt solution and Fowler position in certain cases of peritonitis and the time may come when, as Dr. Neate

advocates, cultures are taken at all operations on pus cases, with a view to the saving of time if vaccines are needed later on.

MELTED IODOFORM OINTMENT IN THE TREATMENT OF SUPPURATING BUBO AND ISCHIORECTAL ABSCESS.*

By H. A. ROYSTER, A.B., M.D.,

RALEIGH, N. C.

Nothing is unimportant in the practice of surgery. Some things are more important than others and due weight should be allotted to each matter in its proper relation. A book written wholly in italics has no force; everything emphasized is nothing emphasized. Attention to detail is a good watchword, provided it does not lead one to mistake the less for the greater, but, under no possible circumstances, is carelessness or negligence ever excusable. Whatever is worth doing is worth doing well. In a former paper† I have contended that the term "minor surgery" has no place in our nomenclature and that those who insist on the division of surgery into major and minor must be content with this definition: "Minor surgery is that part of surgical practice which is done by the minor surgeon." There is really no intelligent line of demarcation. It is all surgery and the same discriminating care should be bestowed upon a finger amputation as upon the removal of an abdominal tumor.

With these observations as a preface, it is my privilege to ask your attention to a rather scattered discussion of two common surgical ailments which constantly confront the general practitioner. These affections will be considered entirely from the viewpoint of the average physician and the suggestions made are such as may be carried out by him in his own way.

1. *Suppurating Bubo.*—There is scarcely a practitioner who does not treat many cases of inguinal bubo every year and, I may say, hardly one who is satisfied with the methods usually advised and employed. The textbooks tell us to keep the patient in bed during the early stages with poultices or ice bags upon the parts; to make a free incision when pus forms and pack until healing is complete, or to do a formal excision of the glands under general anesthesia. Any or all of this means a protracted course of treatment and long confinement to bed, just the very things which it is desirable to avoid. About twelve years ago I hit upon a plan for handling these cases and it has proven so gratifying that I am constrained to give it in its details. I published it in a desultory fashion at the time I first took it up. The basal idea itself is not original with me and I do not now remember whence I derived it, but the practical application was evolved in my own work. Briefly, the principle is that of attempting to promote resolution of the inflamed glands, to secure rapid pointing if suppuration occurs, and, finally, to evacuate the pus and fill the cavity with melted iodoform ointment. Long before the bismuth paste method was even heard of this ointment method was used by me for buboes.

When the inguinal swelling first begins daily application is made of a salve composed of equal parts of pure ichthyol and the official ointments of iodine, mercury, and belladonna. A small portion of this is rubbed in well and another portion spread thickly on a gauze dressing, which is held tightly against the area by a spica bandage. If absorption fails to take place and breaking down ensues, as generally happens, the following procedure is carried out, when the suppuration is at its height. A spot on the softest and most prominent part of the swelling is infiltrated with a 1 per cent. cocaine solution and a very small incision made here with a bistoury—an opening just large enough to let out the pus. When the cavity has been emptied by the aid of pressure it is washed out two or three times with hydrogen peroxide, diluted one-half with sterile water, followed by flushing with sterile water alone. For these washings an ordinary glass piston syringe is used. A quantity of 10 per cent. iodoform ointment is now melted (it can conveniently be done in a large spoon over a gas, alcohol, or oil flame), sucked up into the same syringe, and injected into the suppuration cavity with some force, so as to completely fill it. Over this is immediately placed a cold bichloride gauze compress, which is retained by the spica bandage as before. The dressing is not disturbed for five days. At the end of this time it is removed and the excess of ointment is squeezed out; if any pus remains a second injection of ointment is made; otherwise the gauze and bandage are reapplied for some days longer. In the vast majority of cases one treatment suffices to cure. Exceptionally a broken down gland or two may have to be removed weeks or months later, but under these conditions a clean incision can be made and closed without drainage. During all of this treatment, both early and late, the patient need not go to bed or even lose a day from his usual occupation. I have records of some sixty cases in the hands of myself or my assistants and out of this number only two have required further interference. Neither of these was under our care from the beginning. Instead of iodoform one may use any other substance of like nature, such as aristol or nosophen. I have employed these also. Recently we have tried Beck's bismuth paste in a few cases and our experience leads us to believe that iodoform is still the best.

2. *Ischiorectal Abscess.*—This affection, while not at all related to bubo, affords an opportunity of applying the method just outlined, thereby saving the patient time and trouble. It is pertinent first to state that much carelessness, not to say ignorance, is yet exhibited in the management of these cases. Unless an early incision is made there is almost sure to result a fistula in ano, and most of these are caused by delay. Without exception these abscesses should be opened before they point. This was the teaching even in the old days, when the rule was to wait for "risings" to get "ripe." Surely there is no reasonable justification for one who waits for an ischiorectal abscess to "come to a head." And, yet, one still sees physicians putting on poultice after poultice, applying antiseptic mud paste, and narcotizing the patient as he lies suffering on his bed. A glance at the pathology of perirectal infections will further emphasize the need for immediate incision. The cellular tissue in this region possesses low vitality. It is liable to septic invasion through the blood stream or through the lymphatic channels. A direct communication with the bowel is rare. The lymphatic way is probably the most common—a sort of seeping process

*Read before the Fourth Councillor District Medical Society, Goldsboro, N. C., November 8, 1910.

†*Old Dominion Journal of Medicine and Surgery*, March, 1909.

through abrasions in the rectal mucosa—and when pus is formed in the areola tissue it must find an outlet one way or the other. If it perforates the bowel, and this is the direction of least resistance, the result is a fistula; if it progresses toward the skin surface (the safer way), extreme suffering and slow healing are the penalties. The pus should not be allowed to project itself in either direction, but should be evacuated through an external incision before it has a chance to burrow. In the early stages there is practically never any opening into the rectum, so that fistula in ano might almost be unknown if it were the universal practice to incise abscesses in this region before they break through into the bowel. How any one can offer a sane pretext for procrastination it is hard to understand.

Granting, then, that an early incision is to be made, I suggest the same method here as I have proposed for the bubo, with this exception: that the dioxide of hydrogen be omitted for fear of causing penetration of the rectum by the evolved gas. As soon as all the pus has escaped through the small opening the cavity is simply washed with a one to two thousand solution of bichloride of mercury and the ointment is injected as described above. This is infinitely superior to the directions generally given in books and practised by those who follow them blindly. Having used the ointment in one case, one will never again resort to the plan of long incision, painful packing, and frequent dressing.

Our results have been equally as good as in the buboes. It was only about five years ago that we adopted this method for ischiorectal abscesses and consequently the number of cases is not so large. And those who are specializing in surgery see comparatively few of these cases in the early stages or even at the abscess period, but most often get them after the fistula has formed. It is the general practitioner who first finds these threatening infections and upon him devolves the responsibility of doing the right thing at the right time. If I have succeeded in lending him the assistance of a suggestion or two in the treatment of these ordinary conditions, that he may manage them safely, intelligently, and easily, I shall feel abundantly pleased.

IS CANCER CONTAGIOUS?

A REPORT OF FIVE CASES WITH FOUR DEATHS.

By GEORGE D. WHITE, M.D.,

JERSEY CITY, N. J.

It has long been thought by some that this dreadful disease is contagious, and cases have been reported from time to time in the literature which seem to indicate that such a possibility is not without solid foundation. People in whom no history of heredity could be traced and who were apparently in perfect health have moved into houses where cancer patients had lived and died, and have developed malignant disease; not only is this true of houses, but certain districts seem to be responsible in a measure for some cases. These reports are scattered through the periodicals embracing places whose geographical distribution would seem to preclude the possibility of their inhabitants being related by blood.

The instance of several healthy rats developing malignant disease in a cage previously occupied by infected rats has been reported by Dr. Gaylord, of Buffalo, N. Y. This cage had been stored in the basement of his laboratory for one year; it had been neither disinfected nor sterilized; at the end of that time it was taken out and healthy rats were placed therein; several of these in the course of time developed malignant disease in typical form.

It is such reports as the foregoing which to my mind strongly point to the possibility of contagion of parasitic or bacterial nature as the etiological factor in the propagation of the disease. I believe the following cases of sufficient allied importance to warrant their report. These were five cases of malignant disease with four deaths that came under my observation within the last five years. A report in detail is as follows:

Case I—Mrs. M., aged 43 years; housewife; two children; came to my office in 1905, with the following history: After suffering from the usual symptoms for months she called in Dr. J. M. Rector, a surgeon of Jersey City, N. J., and sought his advice. After a complete physical examination and microscopical examination of scrapings from the uterus, the report of a competent pathologist showed the case to be one of carcinoma. Operation was refused and the patient went on getting worse from day to day, and when at last her sufferings compelled her to seek relief metastasis had already taken place in other organs and the case was inoperable; the patient died shortly afterward.

Case II—In 1906, Miss H., native of Ireland, aged 64 years; sister-in-law of Mrs. M. (Case I), gave the following history: She had always enjoyed good health until six months previous. There was no family history of cancer. The menopause having occurred at the age of 45 years no symptoms appeared until six months ago when she began to notice at irregular intervals bright red blood coming from the vagina. From her history and physical examination I suspected cancer and had her sent to the hospital, where she was found to have an inoperable carcinoma of the uterus. Death occurred in one month from the time of admission to hospital.

Case III—In 1908, Mrs. N., aged 62 years, sister-in-law of Miss H., (Case II), and living in the same house, called me in and I elicited the following history: Family history in regard to tuberculosis and cancer, negative; has had three children, two of whom are living and in good health; she has always been strong and in good health until the present illness. The menopause occurred at 48 years. Two months ago she discovered bright red blood coming from the uterus. Dr. J. M. Rector, called in consultation, etherized patient and took scrapings from the uterus. The report of the pathologist showed a rapidly growing carcinoma. Operation was performed at once. A complete hysterectomy was done and the uterus subsequently examined verified the pathological diagnosis. The patient lived five days, when death took place from an intercurrent pneumonia.

Case IV.—In 1909, Mr. M., aged 54 years, brother of Mrs. N. (Case III), and husband of Mrs. M. (Case I), came to my office with the following history: Sister died as previously reported in Case III; otherwise no history of either cancer or tuberculosis in family. Always enjoyed the best of health, worked hard, was a moderate drinker and an excessive smoker; for the past month he noticed that his throat felt sore, there being some difficulty in speaking as well as swallowing. From the history of the case I thought it might be one of can-

cer and sent him immediately to St. Francis Hospital for examination by the visiting throat specialist. A diagnosis of inoperable cancer was made, and after the greatest suffering death occurred in three months. This man had continued to occupy the same bed in the same house in which his wife had previously died of cancer.

Case V.—In 1910, Mr. N., aged 65 years, husband of Mrs. N. (Case III), and brother of Miss H. (Case II), applied to me with the following history: He has continued to occupy the same room and bed in which his wife died. He always enjoyed good health until last year, when he noticed a small, dark, non-painful mass in the region of the parotid; this has progressively and painlessly enlarged until at the present time it is a large ulcerating mass the size of half an apple. There seems to be no involvement of the cervical glands, but the cancerous cachexia is well marked, the higher mental functions seem to be seriously impaired and the patient acts strangely child-like. This case is inoperable and death will probably take place within six months.

Here we have five people, four of whom have died, three in one house and two in the other, all either related by blood or living in close association with one another in the capacity of husband and wife. Those interested in this subject may draw their own conclusion, but I wish them to pay particular attention to the fact that the five victims have all been infected within the last five years.

A CASE OF MULTIPLE PREGNANCY WITH ECLAMPSIA.

By EDWIN A. GRIFFIN, M.D.,

BROOKLYN, N. Y.

A primipara, twenty-nine years of age, of Polish nationality, weighing about two hundred pounds, was brought into St. John's Hospital, Brooklyn, in a state of unconsciousness, convulsions occurring every five minutes. Her entire body became as cyanotic as indigo; her temperature was 101, respirations 40, and pulse 120, irregular and of high tension (about 200 mm. Hg.). Examination revealed multiple pregnancy at full term; two fetal hearts were detected; the cervix uteri was one and a half fingers dilated, and the membranes were intact. Urinalysis showed a large amount of albumin, the urine boiled solid upon the application of heat and the addition of acetic acid. The ankles and face of the patient were to a moderate extent edematous.

The patient was given chloroform to the obstetrical degree, just enough to control the convulsions, and the cervix was manually dilated and three children were delivered. The first, a female, weighing about four and one-half pounds, I delivered by podalic version; the second, a male, weighing about six pounds, was a breech presentation, and was delivered as such; the third, a female, weighing about four pounds, I also delivered by podalic version. The three children were delivered in a period of about four minutes. The first two had spontaneous respiration; the last one, the smallest, was extremely cyanotic; in this case artificial respiration by the various methods had to be resorted to, bringing forth a lusty cry in about ten minutes. Chloroform was then discontinued and two placenta with three cords, two being attached to one placenta, were expressed by the Credé method. A moderate postpartum hemorrhage followed which I arrested by a hot saline intrauterine douche and by pressing the fundus uteri down deep into the pelvis.

Postpartum eclampsia treatment was then instituted, *i.e.* hot packs, high colonic irrigations, nitroglycerin, tincture of veratrum viride, cathartics, etc. These were all discontinued in about twenty-four hours.

The next morning the patient became conscious and was able to nurse one of the triplets. When the children were presented to her she immediately grabbed the largest, the boy, and applied him to her breast, absolutely refusing the ownership of the other two, stating that they did not belong to her and the hospital would have to take care of them, also saying how could she have three babies as she had been married only one year. It was only by the persistent persuasion on the part of the father and nurses that she finally consented, against her will, to acknowledge the other two, while still refusing to nurse them from her breast, so I was obliged to put the two little creatures of humanity upon modified milk which they took well and upon which they gained in weight.

Urinalysis after twenty-four hours showed a trace of albumin and in ten days the albumin had completely disappeared. On the eleventh day the fundus uteri was at the pubes and the lochia disappeared. The patient, together with her new family of triplets, was then discharged.

475 Putnam Avenue.

Fractures of the Femur in the Course of Ankylosis of the Knee.—E. Kirmisson calls attention to the production of a fracture of the lower end of the femur in the course of anchylosis of the knee joint and showed a patient having this complication. The cause is the lessening power of the quadriceps extensor which occurs with the ankylosis. The biceps being the strongest of the flexors causes the leg to be held in a position of adduction and rotation outward, forming a solid lever. In movements, or after a fall, it is the bones that yield, instead of the ligaments. The ankylosis also causes trophic changes in the bones and they become abnormally fragile and break easily. The patient in question showed general joint disease following scarlet fever, which the child had at the age of five years, six years before he was seen by the author. After the ankylosis was partially established a fall fractured the lower end of the femur in the manner described. The author has seen eleven similar cases.—*Le Bulletin Médical.*

Treatment of Diabetes Mellitus in the Child.—Marius Lauritzen states that early diagnosis is important in children because the late cases almost always go on to a fatal issue in spite of treatment. In families where there are cases of this disease or of other nutritive diseases it is advisable to make periodic tests of the urine for sugar. When acne, furuncles, or other skin diseases show themselves we should think of diabetes. The first thing to do in treatment is to find out the tolerance for carbohydrates by the use of such a diet as the following: 30 to 50 grams of rice cooked in milk, 25 grams of fish, 100 to 200 grams potatoes, 25 to 75 grams bread, varied with the age of the child. The urine for the twenty-four hours is then tested. If glycosuria increases we must put the patient on a strict diet. In mild cases the sugar disappears easily under diet alone, and here the prognosis is good. But in severe cases little effect is seen from diet, and the prognosis is very bad. Trauma has little to do with the etiology, and there are no evidences of disease of the pancreas in children. It is important to know that in many cases it is necessary to reduce the albumenoids as well as the carbohydrates to get rid of the sugar, since the albumins may be turned into sugar. The author varies the diet thus: a few days of strict diet, then a day of vegetables, then a few days of oat-meal diet, then a return to severe diet, and so on. In severe cases the use of fats and albumins brings on a condition of acidosis, and the alkaline condition of the blood is interfered with. To combat this the alkaline treatment is instituted. In mild cases no drugs are necessary.—*Archives de Médecine des Enfants.*

ALCOHOL IN THE TROPICS.

IN the United States *Naval Medical Bulletin* for the quarter ending January, 1911, is a paper on problems of sanitation in landing and expeditionary service in tropical and subtropical regions, translated from the German of Dr. Riegel of the German Navy. Dealing with the question of the use of alcohol in the tropics the writer says that most physicians reject absolutely the regular use of alcohol in tropical expeditions, even though they are not otherwise opposed to alcohol. Far greater, however, is the number of physicians who advocate total abstinence from alcohol in the tropics. The harmful effect on the heart which alcohol exerts in combination with military marches in the tropics is pointed out. According to the observations of Martin in the Celebes, an intimate relationship may easily be recognized between heart affections and the habitual use of alcohol in military exertions. Moreover, alcohol causes a dilatation of the vessels of the skin, a part of the vascular system which is already overworked by the process of heat regulation, and therefore particularly in need of rest. Attention is also drawn to the fact that the fat-conserving property of alcohol which, in a sense, raises it to the class of foods, should not be considered for the reason that, unlike fats and carbohydrates, it is not stored up, but on the contrary, is rapidly consumed even when no immediate necessity exists. The conclusion reached then is that the use of alcohol as a daily drink, as a refreshment rewarding special exertion, as a means of diversion, or as a dispeller of care, should be emphatically opposed for reasons of health in any expedition in the tropics.

The writer appears, however, to be by no means certain that the use of alcohol in the tropics should be wholly dispensed with, as it sustains heart action and muscular strength, though only temporarily, and consequently, given in small portions, helps the hungry and exhausted. Therefore, in rare instances, "its use might be justifiable, for example, when it is necessary to take an enemy's position by storm in a final assault with hungry and wornout troops who must be called upon to give their final stimulated effort."

There is no unanimity among the members of the medical profession as to the value or otherwise of alcohol. True it is that its value has largely fallen in the estimation of physicians, both as a medicine and as a beverage. There is an influential section of scientific men who can distinguish no good in alcohol whatever and regard it as a poison and nothing else, but the great bulk of the profession and probably the majority of scientific men do not hold extreme views on the matter. While freely admitting that the abuse of alcohol is harmful in a high degree and that in the past its merits as a drug or beverage have been greatly overestimated, these are yet chary of condemning it entirely. Their argument might be that while it has been proven that the value of alcohol has been exaggerated, it has not as yet been made absolutely clear that it is in all circumstances the virulent poison which its opponents assert that it is.

The writer in the *Naval Medical Bulletin* appears to be of this opinion. Perhaps alcohol is more harmful in the tropics than in the temperate climes, but there may be occasions when its employment is indicated. Investigations into the question are still being undertaken in various countries, and it is possible that the time will come when an ultimate decision will have been made. In the meantime, it may be wise not to express too dogmatic views on the matter.

STATE SICKNESS AND INVALIDITY INSURANCE.

FOR many weeks past there has been going on in the columns of the *British Medical Journal* a warm correspondence relative to the proposal contemplated by the English Government of adopting in the near future a system of State invalidity insurance. The British Medical Association has already been appealed to by the Government to suggest a feasible plan for carrying out this project. Ignorance as to the exact scope of the proposed extension of governmental paternalism and fears as to the possible effect of such activity on the already precarious incomes of medical men have created a state of mind akin to consternation in the ranks of the English profession. This attitude cannot be without interest to American practitioners who may some day be called upon to face similar problems. A clear exposition of the attitude of the British Government and of the plan best adapted to conserve the interests of the State, the people and the profession, is provided in the address delivered by E. Rowland Fothergill before the Hampstead Division of the British Medical Association, and published in the Supplement to the *British Medical Journal*, January 21, 1911. He states that from various sources information has been obtained which indicates that probably within the coming year the English Government will introduce an insurance scheme which will include the following: It will affect 15,000,000 persons; it will be compulsory and contributory; it will be limited to those between the ages of 16 and 70; it will affect all whose income is below £160 ($800); it will be worked partly through the permanent friendly societies and insurance companies dealing with sickness insurance, and partly through companies or societies formed for similar purposes.

In view of these purposes of the British Government it is quite natural that the profession should understand and finally make known its own attitude with regard to this sweeping innovation. The most important question is that of remuneration, and on this point Fothergill sounds the note of warning, that if the medical profession at this crisis should decide to accept as adequate remuneration for its services a sum, the determining of which has been influenced either by thoughts of charity, or by want of due appreciation of the extent of the services required, or by appeals to its sympathy for the accumulating burdens of the State, or by lack of union amongst its members, then it most certainly will follow that the very value placed by the profession on its services will come in course of time to be recognized as the true value, and permeating slowly but surely amongst the upper classes, will be eventually demanded by them also as a right. In other words, the profession should not sell itself into the hands of the State, and ultimately into the hands of the public at large.

As regards the actual management of the business of insurance, it is noted that while the organized profession may cooperate in the elaboration of a scheme, and while it may use its organization for the disciplinary control of its members, and for voicing the wishes of the profession, the actual responsibility of dealing with the intricacies of an insurance business should be left to the State. The latter should take all risks.

The institution of State invalidity insurance is to be regarded from all viewpoints as a business proposition, and free from motives of charity. Two important points are emphasized. First, it should be possible to place the beneficiary under the scheme in exactly the same position in all respects as that held by a person whose financial state renders an insurance unnecessary. Second, there must be a maximum to the amount of benefit which can be drawn both absolutely and in relation to the amount of contribution paid.

Among the points that Fothergill correctly regards as essential in the elaboration of any scheme of governmental health insurance are the following: The scheme should include women and children. It should not include those coming under the Poor Law. There should be central and local boards and committees for the control and conduct of the service. On all these boards and committees there should be adequate representation of the medical profession. There should be central and local medical committees. Each beneficiary who pays in whole or in part his premium of insurance should have the right to choose his doctor. The service should be open to all registered medical practitioners who care to participate in it.

In considering the question, "on what basis should the contract with the doctor be made," it is noted that there are three possible modes of contract: Whole time appointments, payment by a capitation fee, and payment per attendance. The objection to the first of these is that it would remove the choice of doctor from those who up to now have had free choice while paying for his services; it would deprive many medical men of the larger part of their practise, and absolutely ruin many others; it would tend to perfunctory attendance on the part of the doctor under his three taskmasters—the State, employers, and employee; and it would fail in any attempt to carry out the ultimate aim of the whole scheme—namely, the improvement of the physical condition of the laboring classes by the prevention of disease. With regard to the remaining alternatives, namely, payment by a capitation fee and payment per attendance, one of the main disadvantages associated with the former is that the medical practitioner takes over the insurance risks rightly belonging to the State. There should be payment made to all classes of the medical profession in direct proportion to services rendered on a tariff based on "payment per attendance."

In concluding his masterly discussion of this subject, Fothergill states that by the adoption of a plan such as he delineates the medical profession, while freeing itself from the servitude which seems to be gradually overwhelming it, would be best assisting the improvement of the physical conditions of the laboring classes and helping to the success of a national scheme of State invalidity and sickness insurance.

MEDICAL EDUCATION.

There is much discussion nowadays concerning methods of medical education. This is not only the case in America but in Europe generally and in Great Britain in particular, although perhaps the problem here is more complicated and more difficult to successfully solve. In *Science*, December 30, Prof. E. R. Le Count of Rush Medical College, Chicago, discourses on the subject at some length. The article in question is entitled An Experiment in Medical Pedagogy (it was an address before the class graduating at the end of the last winter quarter) and the personal note runs throughout. Le Count appears to have adopted methods of medical training which have not been popular with students under his charge, and the article is a defence of the attitude taken by him. Le Count is profoundly dissatisfied with many of the modes of training which prevail in medical schools in all parts of the country, and especially is he opposed to didactic teaching, and he deplores the lack of a hospital in connection with the Rush Medical College in which to teach medicine. Another method of teaching with which he falls foul is the work of the so-called hospital class, "a class prepared by written and oral so-called 'quizzes' for hospital examinations, particularly for the written examinations conducted under the civil service regulations which govern the securing of places as residents in Cook County Hospital, the large charity hospital of Chicago. The system of preparation is essentially one of cramming." The work of the so-called hospital class, Le Count is convinced, is of such a character as to cultivate in the minds of the students the notion that accurate diagnosis represents the Ultima Thule of their inquiries—the finality of medical education. He considers that diagnosis is not the end of the journey, but should be merely

looked upon as a breathing place, and that to teach it is the end of the journey will assuredly spell disaster. The experiment in pedagogy made by the writer was the abandonment or partial abandonment of didactic instruction in pathology which has now been going on in Rush Medical College for almost nine years.

Le Count claims that the results brought about by his manner of teaching fully justify its continuance. His object seems to be to make the student comprehend his subject with as little aid as possible; in fact, to worry the matter out for himself. There is no doubt that although such a method is inconvenient to most students, a knot which a student has to use his intelligence to disentangle will not quickly be forgotten, as it probably would be if he were informed exactly how to untie it. That which a man learns by sweat and travail impresses itself indelibly on his mind, and so far Le Count appears to be in the right. On the other hand, perhaps, it might not be well to carry the method too far, as a little help at a critical period will save much time and energy. However, taking into consideration the fact that the output of medical men in this country considerably exceeds the demand, it would seem to be wise to limit the output by making the medical course and examinations so difficult as to eliminate the unfit. Certainly the education of the medical student should be practical and it should be borne in on him that when he is qualified he is really only commencing his studies.

SMALLPOX AND VACCINATION IN LATIN AMERICA.

The *Southern Californian Practitioner* draws attention to the reports on smallpox from the delegates to the Fourth International Sanitary Conference of the American Republics, held some time ago in San José de Costa Rica. According to the testimony of several delegates, notably from Panama, Honduras, and Costa Rica, in which places compulsory vaccination has long been in vogue, smallpox has been conspicuous chiefly by its absence, and when some cases of the disease have occurred they have been invariably of a mild character. On the contrary in Chile and San Salvador, in the former of which vaccination is not compulsory, and in the latter has not been long enforced, the disease has been extensively prevalent and the fatalities numerous. For instance, the delegate from Chile stated that "smallpox has been the infecto-contagious disease that has done the most damage in our country. During the present year, from January 1 to November 30, in Chile, we have had in the single lazaretto in San José 3,800 cases, with 3,071 deaths, while the cases treated in homes have been incalculable."

A recent report to *The Sun* states that after many months of effort the Republic of Guatemala has been freed from smallpox through the very effectual expedient of vaccinating every individual in the country. The whites have always submitted voluntarily to the inoculation, but the Indians have refused by reason of their superstitious fears. Recently the disease became epidemic, and the President of the Republic was persuaded to issue an edict making vaccination compulsory. The work has been continued for three months, the soldiers concentrating the Indians, and every physician in the country being called on to help. As a result, the disease which has been the scourge of the nation has been entirely stamped out, and for the first time the ports of Guatemala are now free from all contagious diseases and passenger travel is without restriction.

Evidence of this description should be spread far and wide, so that the general public may learn from unimpeachable sources the value of vaccination. Scepticism concerning the merits of vaccination appears to be growing in this country, and it is therefore well that the matter should be thoroughly ventilated.

Pollution of the Great Lakes.

In the Public Health and Marine Hospital Service report for the year 1909 reference is made to the pollution of interstate waters. From a perusal of the report of the Lake Michigan Water Commission, issued recently, and as a result of other studies bearing on the question, it is plainly evident that the time is near when measures will have to be put into force to prevent the further pollution of the water of the Great Lakes. It is said that Lake Erie is becoming dangerously polluted on account of the discharge of sewage of cities and towns situated on its shores. Attention is drawn to the undoubted fact that the Great Lakes must in future be the source of water supply of more than one-fourth of the population of the United States; that these lakes are already polluted in certain places and that further pollution should be stopped, both from the standpoint of the public health and from the standpoint of abolishing nuisances. Especially are the cities placed at the outlet of the Great Lakes liable to the danger from the sewage-polluted waters from other States. However, little argument is required to show clearly that steps should be taken to prevent further pollution of the Great Lakes. The matter of water pollution is a serious one throughout this country and, perhaps, in the State of New York more serious than in any other part, on account of the greater density of population. The conclusion arrived at by the Niagara Frontier Pure Water Conference, or rather by a number of its members, who visited the bureau of the Public Health and Marine Hospital Service in January, 1909, that the pollution of interstate water is a matter for federal intervention seems reasonable. The time is ripe and more than ripe for effective measures to be taken for the prevention of water pollution in every section of the United States.

News of the Week.

Ravages of the Plague.—The Viceroy of Manchuria estimates that the fatalities from the plague in Manchuria have been 65,000, but this is declared by many to be little more than half of the actual number of deaths. Practically none of those stricken recover; infection of the lungs being rapidly followed by death. In the province of Harbin 250 deaths are said to occur daily, and as the frozen ground makes burial impossible, conditions are very serious. The people, however, have finally

begun to consent to cremation. At Vladivostok efforts to enorce sanitary regulations resulted in a fight between Russian soldiers and Chinese residents, in which six persons were killed. London has been startled by a report that German agents in Manchuria are shipping to Europe large quantities of hair taken from the bodies of victims of the disease. It is said that the bodies of the dead found in the streets are invariably without queues, and that these are cut off to supply the demand for false hair. Whether the germs of the disease can be transmitted in this way, however, is more than doubtful. The Department of State at Washington has been advised that the opening session of the medical congress for the investigation of the plague will be held in Mukden on April 3.

Dr. Stephen Smith of New York was the guest of honor at a dinner given at the Hotel Plaza on February 18 to celebrate his eighty-eighth birthday. Two hundred physicians and their friends joined in the tribute to their colleague. Among the speakers were, besides Dr. Smith, Dr. Abraham Jacobi, Dr. Joseph D. Bryant, Dr. C. F. MacDonald, Prof. Charles S. Chandler, Mr. William R. Stewart, and the Rev. Dr. R. S. MacArthur

Indian Medicine Man.—Levi Phillips, the last remaining Indian "medicine man" on Long Island, dietd on February 10, aged 102 years.

Harvey Society.—The sixth lecture of the Harvey Society will be delivered by Prof. W. E. Castle of Harvard University at the New York Academy of Medicine, 17 West 43d street, on Saturday evening, February 25, at 8:30 Prof. Castle's subject will be "Unit Characters in Heredity."

Anti-Meningitis Serum.—The Rockefeller Institute for Medical Research of New York announces that it has decided to discontinue the general distribution of anti-meningitis serum which it has carried on without charge since the discovery of this remedy. The work of preparing and distributing the serum will be turned over to public health authorities and commercial establishments, the New York City Department of Health being the first to undertake the regular production of the serum. The distribution of the serum will at first be free to all hospitals and physicians desiring it: but later such gratuitious distribution will be limited to hospitals and needy cases. Until centers of production can be evolved in other localities the New York Health Department will supply the serum on urgent requests from outside the State. Statistics show that the death rate from cerebrospinal meningitis has been reduced to less than one-third by the early use of the serum. Its efficacy being thus established the Rockefeller Institute will devote to other lines of research the money which has been expended in the production of the serum.

Epidemic of Grip.—A severe epidemic of influenza is reported from Berlin. Fourteen thousand cases are said to exist in the city.

A Lutheran Hospital.—Announcement has recently been made of the formation of the Society of the Lutheran Hospital, whose object is to build a hospital, probably in Upper Manhattan. The determination to build is the outcome of the district medical service which has been carried on among needy Lutherans for the past year

City Milk Depots.—The New York Sinking Fund Commission recently leased the following sites at which municipal milk depots will be maintained: Manhattan—108 Cherry street, 209 Stanton street, 164 Avenue C, 2287 First avenue; the Bronx—648 Morris avenue; Brooklyn—139 Osborn street, 651 Manhattan avenue, 126 Dupont street, 698 Henry street, 176 Nassau street, 1001 Flushing avenue, 303 Williams avenue. The depots will be under the direction of the Health Department, and will, it is estimated, cost the city about $40,000 a year. They will deal principally in milk for infants, and will pasteurize at a nominal charge any milk that is taken to them.

To Improve the Philadelphia Milk Supply.—A commission, consisting of Drs. C. Lincoln Furbush, chairman; Henry Leffmann, Randle C. Rosenberger, Clarence J. Marshall, and Samuel McClintock Hamill, secretary, has, after a study of four months, made a comprehensive report to Mayor Reyburn. They recommend that the retail price of milk be fixed at nine cents and the wholesale price at five cents a quart; the establishment of a bacterial standard, to insure cleanliness: the acceptance of a uniform temperature standard of 50°; rigid inspection of dairy farms; prohibition of milk shipments in unsealed packages; night shipments; the adoption of lower freight rates and better railroad schedules, to enable the farmer to realize a legitimate profit. They suggest cooperation with the State Livestock Sanitary Board in the inspection of dairy farms and bottling places. Regulations are laid down for the construction of stables, details are outlined for the proper care and condition of cow stables, ventilation, lighting, disposal of sewage and water supply. In the presence of disease in the family of the dairy man, the sale of milk from this source should be interdicted, and the dairyman reimbursed for his loss. It is recommended that milk cans be labeled with the name of the owner and the standard quality of the milk to prevent exchange of cans and contamination. Cans should be sealed and be opened only by inspectors. Icing houses should be constructed and refrigerator cars provided by the railroads so that the milk can be kept at a uniform temperature of 50° till it reaches the consumer. Morning and evening milkings should be shipped on the same day, at evening, to insure more expeditious handling by the railroads and a fresher supply. Inspection of places where milk is offered for sale is recommended. Condensaries and creameries should be regulated. Careless vending of milk and ice cream should be prohibited. Milk dealers should be licensed and their places of business open and subject to rigid inspection. The establishment of pasteurizing plants is proposed. Chemical standards for milk are advocated. Whole milk should contain 3.25 per cent. fat and 8.5 per cent. of solids apart from fat, and cream should contain not less than 16 per cent. of fat. Guaranteed milk should come from tuberculin-tested cows, and it should be bottled at the dairy.

Corinna Borden Keen Research Fellowship of Jefferson Medical College.—The accumulated income of this fund now amounts to $1,000. The Fellowship will be awarded by the trustees upon recommendation of the Faculty to a graduate of the Jefferson Medical College of not less than one nor more than ten years' standing, upon condition that he shall spend at least one year in Europe, America, or elsewhere, wherever he can obtain the best facilities for research in the line of work which he shall select, after consultation with the Faculty; and that he shall publish at least one paper embodying the results of his work as the "Corinna Borden Keen Research Fellow of the Jefferson Medical Col-

lege." Address Dr. J. W. Holland, Dean, Tenth and Walnut streets, Philadelphia.

The Harben Lectures.—Dr. Simon Flexner of the Rockefeller Institute for Medical Research, New York, will deliver the Harben Lectures of the Royal Institute of Public Health of London for 1912.

University of Pennsylvania.—Dr. John B. Deaver has been elected professor of clinical surgery in the Medical Department of the University of Pennsylvania, succeeding Dr. Edward Martin, who was recently elected John Rhea Barton professor of surgery. Dr. Milton B. Hartzell has been elected professor of dermatology, succeeding Dr. L. A. Duhring, who recently resigned. Dr. J. Williams, formerly John Rhea Barton professor of surgery, has been elected a member of the Board of Trustees.

Dr. Charles Hugh Neilson of St. Louis has been appointed professor of medicine in the St. Louis University Medical School. Dr. Neilson has for the past six years occupied the chair of physiological chemistry in the university. He is a graduate of the Rush Medical College.

The Sloane Hospital for Women.—In order to provide for the enlarged scope of the work at the Sloane Hospital, a new building for the care of gynecological cases has been erected and will be open for the inspection of the medical profession and friends on Wednesday, March 1, from 2 until 6 o'clock. The original name of the hospital, The Sloane Maternity, was changed in December, 1910, to The Sloane Hospital for Women, in order to correspond with the extended character of the work. The hospital is located at the corner of Fifty-ninth street and Tenth avenue, entrance on Tenth avenue.

Pennsylvania Hospital for the Insane.—Dr. Owen Kopp, for twelve years executive head of the Massachusetts State Board of Insanity, has been elected physician-in-chief and superintendent of the Pennsylvania Hospital for the Insane, in succession to Dr. John B. Chapin, resigned.

A New Children's Hospital.—Plans have been completed for the erection of a group of new buildings for the Children's Hospital, Philadelphia, at a cost of $500,000. A plot of ground, 203 by 308 feet, valued at $100,000, has been donated by Mr. Eckley B. Coxe, Jr., one of the managers of the hospital, and provision is to be made for a modern hospital constructed in Georgian style. From the sale of the present hospital, including a dwelling recently donated by Anna McMichael Hoyt, it is expected that about half the cost of the new buildings will be realized.

Consumptives Barred.—The Texas State Department of Health has been notified that the authorities of the town of Llano, about 100 miles north of Austin, have established a strict quarantine against cases of tuberculosis. Persons afflicted with the disease are forbidden to enter or reside in the town.

A Free Dental Infirmary in Boston.—It is announced that Messrs. John H. and Thomas A. Forsyth of Boston are to begin immediately the erection in the Fenway of an institution to be known as the Forsyth Dental Infirmary for Children as a memorial to their brothers, James Bennett and George Hamilton Forsyth. At the infirmary the teeth of poor children will be treated free of charge. Besides providing the land and erecting the building the Forsyths will provide a maintenance fund of $1,000,000. The infirmary will be one block from Bryant street and Huntington avenue, near the Art Museum. The land nearest Massachusetts avenue will be converted into an enclosed park and will be known as Forsyth Park. The building will be of white marble three stories in height with wide marble terraces. The exterior of the building will be elaborately decorated, in keeping with the memorial idea of the institution.

The National Confederation of State Medical Examining and Licensing Boards will hold its twenty-first annual convention at the Congress Hotel, Chicago, on Tuesday, February 28, 1911.

Deutsche Gesellschaft für Chirurgie.—The fortieth congress of the German Surgical Society will be held in Berlin on April 19 to 22, 1911. The president of the Congress for 1911 is Herr Prof. Dr. L. Reim of Frankfurt, a. M., Zimmerweg 16.

Rice County (Minn.) Medical Society.—At the annual meeting held at Northfield on January 28 the following officers were elected: *President*, Dr. Arthur C. Rogers, Faribault; *Vice-Presidents*, Dr. Warren Wilson, Northfield, and Dr. William H. Rumpf, Faribault; *Secretary-Treasurer*, Dr. F. B. Davis, Faribault.

The National Association for the Study and Prevention of Tuberculosis will hold its annual meeting in Denver, Col., on June 20 and 21, 1911, under the presidency of Dr. William H. Welch. The convention will be divided into three sections: Sociological, with Mr. Alexander M. Wilson of Philadelphia as chairman; Clinical, Dr. Charles L. Greene of St. Paul, chairman, and Pathological, Dr. William Ophüls of San Francisco, chairman.

Deutsche Gesellschaft für orthopädische Chirurgie.—The eleventh congress of the German Society of Orthopedic Surgery will be held as usual on the Tuesday in Easter week, April 18, 1911, which is the day preceding the meetings of the Surgical Society, in Berlin. Both societies will hold their sessions in Langenbeckhause, Ziegelstrasse 10/11. Herr Prof. Dr. H. Hoeftman of Königsberg i. Pr., is the president of the Congress for 1911.

Obituary Notes.—Brigadier-General Joseph Rowe Smith of the Medical Department of the United States Army, retired, died at his home in Philadelphia on February 11 of pneumonia, aged 80 years. Dr. Smith was graduated from the Medical Department of the University of Buffalo in 1853, and in the following year he entered the army and was assigned to duty in the Southwest. At the outbreak of the Civil War he was captured by the Confederates at San Antonio, Texas, and on being paroled as a non-combatant was given charge of the organization of army hospitals, and in 1862 was appointed by President Lincoln acting surgeon-general. In 1865 he was appointed medical director of the Seventh Army Corps. He retired in 1895 as assistant surgeon-general and medical director of the Department of the East. Dr. Smith was a member of the American Medical Association, the American Public Health Association, the American Academy of Medicine, and other societies, and had represented the United States Army at many medical congresses both at home and abroad.

Dr. John M. Bradford of Philadelphia, a graduate of the Medical Department of the University of Pennsylvania in 1884, and later resident physician in the Episcopal Hospital, died at his home of nephritis on February 2, aged 49 years.

Dr. Reuben C. Shultz of Los Angeles, Cal., a graduate of the Medical Department of New York

University in 1880, and a member of the California State and Los Angeles County Medical Societies, died at his home on January 19, aged 57 years.

Dr. James T. Estill of Colorado Springs, Colo., a graduate of the Medical Department of Washington University, St. Louis, 1879, died at his home on February 2, as the result of burns received when his dressing gown caught fire while he was lighting a gas stove, in the 62d year of his age.

Dr. David Heinberger of Leadville, Colo., a graduate of the Bellevue Hospital Medical College in 1873, editor of the first newspaper published in Southern Colorado, died at his home on January 27.

Dr. James M. Tinsley of Mt. Vernon, Ill., a graduate of the Medical Department of the University of Louisville, Ky., in 1880, died at his home on February 2, aged 61 years.

Dr. Thomas K. Reed of Atalntic City, N. J., a graduate of the Medical Department of the University of Pennsylvania in 1864, a member of the New Jersey State and Atlantic County Medical Societies, died at his home on February 12, aged 72 years.

Dr. Thomas J. Manahan of Boston, Mass., a graduate of the Medical School of Harvard University in 1900, an assistant surgeon on the Bay State Hospital ship during the Spanish-American War, and afterward a member of the staff of the Massachusetts General Hospital, died at his home of pneumonia after a brief illness on February 14, aged 37 years.

Dr. George W. Seymour of Westfield, N. Y., a graduate of the New York Homeopathic Medical College in 1872, a member of the American Institute of Homeopathy, the New York State Homeopathic Medical Society, and the Western New York Homeopathic Medical Association, died at his home of pneumonia on February 13, aged 70 years.

Dr. James Youngs Tuthill of Brooklyn, N. Y., a graduate of the Bellevue Hospital Medical School in 1864, and a member of the New York State and Kings County Medical Societies, died at his home on February 15, aged 69 years.

Correspondence.

GASTRIC ROENTGENOLOGY.

To the Editor of the Medical Record:

Sir:—The Medical Record of January 14, 1911, contains a very interesting epitome of Gastric Röntgenology, by Dr. E. H. Skinner of Kansas City, in which it is stated that "the use of the *x*-ray in gastrointestinal diagnosis practically dates from the work of Prof. H. Rieder of the University of Munich in 1904." At the risk of seeming ungracious, I want to emphasize the fact that the method was in general use for a considerable period before this date and that, so far as I am familiar with the literature, not one of the main items listed by Dr. Skinner were originated by Rieder. The first use of bismuth and *x*-rays to outline the stomach seems to have been by Roux of Paris in 1896. At about this time Fenton Benedict Turck of Chicago published a report on the location of the stomach by the *x*-ray shadow of opaque flexible sounds, introduced through the esophagus. From the first announcements of Röntgen's discovery I had been interested in the matter, although such experiments as I was able to make were absurdly crude in the light of present advances. Following Turck's announcement I endeavored to devise a method to avoid the introduction of instruments through the esophagus not only on account of the inconvenience to the patient, but to secure information as to gastric peristalis and to obtain a shadow of the entire gastric region. At first I used tablets of reduced iron in a capsule and tried to secure a radiograph after having demonstrated that the tablets gave a visible shadow when held in the mouth. The radiographic method failed, but a little later, in the winter of 1896-7, the fluoroscope gave fleeting glimpses of the capsule, allowing one to approximate the lowest level of the stomach and to note the peristalsis.

Early in July, 1897, after some preliminary failures with bismuth, probably due to imperfect apparatus, I made about a dozen successful fluoroscopic tests with bismuth, corroborating the results of auscultatory percussion of the gastric area. The report was published in February, 1898, in *Medicine* and, by a coincidence, Dorn reported the same method in Europe in the same month. It was not until much later that I learned of Roux's work and Dorn seems also to have been in ignorance of it. Dorn and I obviously could not have known of each other's work. From this time on the development of fluoroscopic and radiographic study of the viscera has been rapid.

So far as peristalsis and sphincteric action is concerned, America may fairly claim Cannon as an authority and this claim would be generally conceded in England and France if not in Germany. In June, 1905, Cannon presented to the American Gastro-enterological Association a paper on "Recent Advances in the Knowledge of the Movements and Innervation of the Alimentary Canal" (*Medical News*, May 20, 1905). The bibliography of this article goes back to 1898 with regard to *x*-ray studies, includes forty-four citations, and does not even mention Rieder. The detection of gastric ulcer by what Dr. Skinner most aptly terms "filling defects" with bismuth was reported as an original observation by Dr. John C. Hemmeter to the same body at about the same date, and the pros and cons of this detail have been discussed to a considerable degree by various writers. In 1908 I enjoyed the privilege of watching the beautiful *x*-ray work of A. Béclére at the Hôpital St. Antoine, Paris. To a large degree Béclére employs fluoroscopy and with such success in regard to peristaltic phenomena, etc., to which radiography obviously cannot be applied until the perfection of the radiocinematograph, and in regard to incipient pulmonary lesions which are commonly declared to require radiography that it is worth while to remind American röntgenologists that fluoroscopy is by no means a dead issue or an amusement of the general practitioner.

There is one particular point in gastric work on which the routine use of the fluoroscope throws considerable light. Allusion is made to the dispute as to which one of the peculiarly shaped shadows designated by the names of Holzknecht, Rieder, etc., represents the normal stomach, and why these bizarre shapes occur as representative of an organ which dissection, necropsy, and operation show to have a very different contour. Allowing for the comparatively slow contractions of unstriped muscle a bismuth radiograph of the stomach is comparable to an instantaneous photograph of a man running, jumping, etc. The camera does not lie, but we all know what unnatural effects it gives in the case of instantaneous photographs, and just as contradictory and distorted effects are obtained when we snap-shoot the stomach at work on a fairly consis-

tent bismuth porridge. Even with a mixture of bismuth in water the fluoroscope at first may give very peculiar shapes as the bismuth is fumbled by the lower part of the stomach. Later, with the diffusion of the watery suspension or thin oily emulsion of bismuth, when the peristalsis has subsided, we get a shadow which is by no means so sharp as that afforded by radiography but still, in most cases, pretty distinct, and this shadow gives one a fair conception of the gastric contour.

Do not misunderstand me to belittle the magnificent work of Rieder nor to attempt to inject into a scientific subject a partisan quarrel. Nor is it my purpose to present an accurate and complete history of röntgenology or of any of its subdivisions. It is a fact not requiring elaborate research but simple recollection of recent events and, at most, reference to easily obtainable medical books and journals, that the pioneer work in the subdivision of gastric röntgenology antedates 1904 by eight years, possibly nine; that the methods had been in practical everyday use even outside of the principal medical centers at least five years before 1904; that most of the items scheduled so admirably by Dr. Skinner were discovered by others than Rieder and even independently of the influence of his researches. Naturally the methods and results are vastly better and more available to-day than they were in 1904 and the achievements of each worker stimulate others and set an increasingly high standard. However, excluding a relatively small number of laboratories and certain details the diagnostic use of the .r-ray in 1904 may still be considered not in the light of an historical curiosity but as a practical, frequent, and well established routine suffering by comparison with the standards of 1911 no more than the automobile or the telephone.

A. L. Benedict, M.D.

Buffalo, N. Y.

OLIVER WENDELL HOLMES AND HIS WORK.

To the Editor of the Medical Record:

Sir:—The letter of Professor Baruch in your issue of the 4th inst. under the caption "Holmes and Semmelweiss" is most interesting and well serves to emphasize the fact that the literary fame of Oliver Wendell Holmes has completely overshadowed his professional record. The latter, indeed, seems to have been forgotten, except by students of medical history. Measured, however, by the good it did his pamphlet "The Contagiousness of Puerperal Fever," published in 1843, is the most important product of his pen. It will always serve to stamp him as an original thinker far ahead of his time.

That the author of "The Chambered Nautilus" should have had no mean part in paving the way for a great discovery in science will seem strange to many, but, after all, why? Surely the muses must love the gentle and altruistic art of medicine. Schiller was a physician and so were Goldsmith and Keats. Goethe never hesitated to avow his love for the study of medicine and in his Sesenheim reminiscences details with enthusiasm his experiences at the clinics of Strasburg. There is abundant evidence that Shakespeare was well versed in the medicine of his time, and so one might go on citing familiar but forgotten instances and not omitting our own Weir Mitchell.

Holmes' name will always be associated with another great discovery, that of anesthesia, for it was he who coined the words "anesthesia" and "anesthetic." It was in his day, and in the city of Boston, that Morton and Warren achieved a great triumph in the successful use of ether, thus gaining for America the credit for that most beneficent discovery. It must have seemed to the delighted but awe-stricken onlookers as though the very breath of God had been breathed into the nostrils of men to take away the sting of a suffering worse than death.

"There were giants in those days." One may wonder what the genial autocrat would say of conditions in "The Hub" of to-day. What he would say of those who deny the existence of disease and the logical result of whose teaching would be the restoration of all the horrors of preanesthetic days and the reestablishment of puerperal fever in home and hospital. What of those who swallow at a gulp the dubious hypothesis of the subconscious mind and would substitute for the noble mysteries of religion the hocus pocus of a pseudoscience? What of those who form societies, write books, and collect statistics to show, as Stanley Hall says, that ten ghost stories make one true story? What of those who from the top notch of transcendentalism proclaim the psychology of Piper and Paladino?

Who can deny that if our poet physician of blessed memory should return to earth he would find field enough for his satire?

George P. Shears, M.D.

FOREIGN BODY IN THE VAGINA.

To the Editor of the Medical Record:

Sir:—I thought it might interest your readers to have me relate to them a curious case of foreign body in the vagina. In July, 1910, there called at my office a young girl 18 years old, a stenographer by occupation, who asked to be treated for "falling of the womb." Upon inquiry regarding her diagnosis of her own case she stated that "for the last six weeks I have had a feeling as if my womb were dropping down." She also stated that "for the last

five weeks I have had a dark, foul-smelling discharge from the vagina."

I placed her on my examination table and endeavored to introduce my index finger into the vagina, but could not penetrate more than half an inch beyond the labia minora, as my finger met a peculiar, hard obstruction. I questioned my patient whether she had inserted any object into the vagina, but this she vehemently denied. I then separated the lips of the vagina, and to my surprise beheld a round tin label with the imprint, "Cook's Imperial." Finding it impossible to remove the object to which this label was attached, it being firmly wedged in the

vagina, I used my double tenaculum, and after some efforts extracted a champagne cork, which had swollen to considerable size, evidently from its prolonged absorption of vaginal moisture. My patient appeared to be very much puzzled at this forced delivery and was at first unable to account for its presence in her vagina, until she suddenly recollected having spent an evening, six weeks previously, with her "gentleman friend," when they both drank considerably and when the cork must have been introduced *in loco parentis*. She suffered no ill effects beyond a marked endometritis, which I promptly relieved by curetting her at the French Hospital. I enclose photograph of the "interesting exhibit."

OUR LONDON LETTER.

(From Our Regular Correspondent.)

SLEEPING SICKNESS AT THE ROYAL SOCIETY. ANOTHER EXPEDITION—YELLOW FEVER—CANCER OF THE RECTUM—TREATMENT OF SCHOOL CHILDREN—DERMATOLOGY—LEAD POISONING—ITEMS—OBITUARY.

London, February 3, 1911.

Last evening the Royal Society held a meeting to receive a report of Sir. D. Bruce's expedition in regard to sleeping sickness undertaken for the Society and the results of his further experiments. Unfortunately Sir David was prevented by indisposition from being present. In his absence the results of the work were summarized by the secretary, Dr. J. R. Bradford. It appeared that experiments had shown that injecting extracts of infected flies produced effects similar to those obtained by allowing flies to transmit the disease directly by biting animals. That is to say, that for the first two days after becoming infected the fly was capable of transmitting the disease. Then for about twenty days it was not capable of doing so. Then it again became able to infect and continued to be for a long period, of which the limits have not yet been determined. Another series of experiments were made to ascertain whether the blood of natives who were being treated by arsenic could transmit the disease through a fly as arsenical preparations seemed to have a controlling influence, at any rate, in prolonging life. It was suggested at one time that arsenic might prevent patients from spreading the disease, but that was not the case, for the experiments showed that flies fed on patients under arsenical treatment might become infected and then transmit the disease.

The Liverpool school's expedition to the Congo on sleeping sickness, which I reported last week, is to be followed by one in another direction and under other auspices. A commission is being arranged to investigate the disease in Northern Rhodesia, where it is said to present distinct differences. The P. M. O., Dr. Aylmer May, is to have the direction and he has secured as colleagues Dr. Leach of the same service; Dr. Kinghorn of the Liverpool Tropical School; Mr. Silverlock, entomologist, and Mr. Jollyman, bacteriologist. This commission is being sent by the British South African Company and will begin work in the Luangwe Valley, where it is thought there is a different type of the disease which is not transmitted by the *Glossina palpalis*. This variety has not been found in the valley or within 300 miles and few of the patients have ever visited the palpalis area. It would seem that a fly which is not limited to the neighborhood of water, but spread over wide areas, must be a more likely agent and the *Morsitans* has been suspected. This will be the first point for the commission to determine. It has also been suggested that an insect which is a carrier under some conditions of climate, especially as to altitude, may not be under other conditions.

The Society of Tropical Medicine has devoted another meeting to yellow fever, anent the paper of Sir R. Boyce, of which I gave you some account in my letter of December 2. You will remember that Sir R. Boyce considered the disease to be endemic in the principal coast towns of West Africa and that it is now more prevalent than is usually supposed. He gave an interesting sketch of the history of the disease in the several towns from which he deduced that it ravaged the early inhabitants of West Africa just as it did those of Central and South America. The way to meet it, he said, was by segregation combined with destruction of the stegomyia. At the further discussion Sir P. Manson disagreed with the opinion that yellow fever was endemic in West Africa, but he endorsed the view of meeting the disease by destruction of the stegomyia. Dr. G. C. Walker, sanitary officer on the Gold Coast, said the scrub around the towns was infested with the stegomyia mosquitoes and if that were kept down the prevalence of the fever would be checked. Professor R. Ross remarked that the mosquito stegomyia was met with all over the continent of Africa, but the fever was only said to be endemic on the west coast. Sir Rubert Boyce replied that the history was of continual outbreaks for 100 years and an almost continuous prevalence for the last twenty years. The natives' death rate was almost inappreciable, but that of whites was 70 to 100 per cent. This enormous difference could only be due to immunity. West Indian negroes were just as susceptible as white newcomers. So blacks had no natural immunity. The source of the virus was in the native races. They harbored the disease in some form as they do malaria. So segregation was preventive. His views coincided with those of official commissions in several countries of Europe and America.

Two meetings of the Surgical Section, B. S. M., have been given up to a discussion on cancer of the rectum, so I can only briefly cite the opinions of the surgeons who spoke. Mr. Swinford Edwards protested against the extensive operations sometimes adopted. The immediate mortality should be set against a problematical lessening of risk of recurrence. Preliminary colotomy in extensive cases was advisable. Of his 81 cases, 4 died, 22 recurred, 14 were not traced. Fixed growths were best let alone. Mr. Harrison Cripps agreed with Mr. Edwards and thought only cases in which the growth was confined to the bowel wall should be operated on. He has seen 1,000 cases in the last thirty years, nearly all were "adenoid," *i.e.* a proliferation of epithelium of Lieberkühn's follicles and the reproduction of those follicles on a large scale. Not more than one in four cases he had seen was at all fit for operation and he held that to operate on all cases would bring discredit on the surgeon and the procedure. It was difficult to be sure at the first examination whether the growth was firmly fixed or not. He had seen many which at first seemed unfit for removal but which were more favorably examined under an anesthetic.

Sir Fred Eve could not admit three years was

a test of cure for recurrence often took place later. Permanent colostomy after abdominoperineal operation seemed to him to afford the best preventive of recurrence. Mr. Waterhouse liked the abdominal operation less and less. He advocated the parasacral route after prolonged preliminary treatment and colostomy when there was obstruction. Mr. Boyce Barrow advocated preliminary colostomy and said that this left permanently was far less objectionable than commonly thought if properly attended to. Mr. Handley agreed that the colostomy gave little trouble. But he disagreed with Mr. Edwards and others as to extent of operation, declaring that the pathology pointed to the propriety of removing an extensive tract of bowel even when the growth was not large. Cancer cells were to be found six inches from the tumor. Mr. Wallis urged the importance of early diagnosis. This, I think, is admitted in those cases as it is in all others where operations are likely to be needed and it is obvious that family practitioners have the best chance of detecting at the earliest moment such cases. Specialists can get the histories when it is too late and they might therefore study these with a view of furnishing hints on early indications. Mr. Mummery out of 100 cases found 57 too late for operation. He thought that such might be the case in about nine months from first symptoms. The sigmoidoscope gave early diagnostic signs. The mortality was due to sepsis in ninety per cent. of operations. Mr. Gordon Watson thought the abdominoperineal the correct procedure. He suggested vaccines as preventives of peritonitis. Mr. Fagge held that in spite of its high mortality the abdominoperineal saved more lives than any other. Two speakers said they had used antistreptococcic vaccines but not anticoli which Mr. Watson suggested. Mr. Godlie, president, testified to the advantage of colostomy and the absence of shock after many abdominoperineal operations.

The medical treatment of school children continues to occupy the attention of educationists and to some extent set them at variance. The Board of Education has addressed a letter to the London committee dealing, among other points, with the hospital scheme and giving consent to the continuance of the existing arrangements for six months longer. The Board further warns the committee that the number of children so treated must not in the meantime be increased. The committee is not satisfied that the six months will suffice for detailed consideration of the plan and asks for the time to be extended to at least the close of 1911 and further that the number of children admitted to the aural department of the London Hospital should not be restricted. The committee has partially discussed the Board's letter, but it has not been made public and the matter will probably linger on in the usual official way.

In regard to the experiment in playground classes made last summer in some of the poorest districts, the medical officers seem to think good was done, as might well be expected, for the open air must be better than that of the schoolrooms. One doctor says that in three weeks he noticed a decided improvement in the children he had selected. The appearance was supported by higher hemoglobin readings at the final examination but he attached more importance to the greater bodily and mental vigor. Some who had been apathetic and morose became bright, energetic, interested in their work as well as improved in color. The anthropometrical details were equally improved. In another school the doctor says listlessness gave place with improved bodily health to alertness. Except one tuberculous child, who was sent to hospital, every case in the playground class showed all-round improved health, but enlarged glands did not decrease to any extent, which he attributed to dental disease being the cause. Here, as elsewhere, anthropometrical measurements are said to have advanced.

The dermatologists are drawing attention to themselves by their discussion. It was once a different branch that was said to be always disagreeing. We have three, if not more, dermatological societies and I seem to remember one or two that no longer have a separate existence. There is a section in the Royal Society of Medicine and one is annually formed in the British Medical Association. It is in regard to the last that the present quarrel seems to have arisen, the merits of which are difficult to decipher or even to find. One gentleman, who seems to be associated with most, if not all, the groups, told me he really thought all the differences were due to disappointments of members, either in their ambitions or their practices.

Two departmental committees have been appointed by the Home Office to investigate the dangers of lead poisoning among painters of (a) buildings, and (b) carriages and coaches.

A practice among weavers called "kissing the shuttle" has been lately talked about by sanitarians and made known to the general public. It seems to thread the shuttle the cotton has to be passed through the small hole called the "eye" and the weavers have long been accustomed to suck it through. This dirty practice is also dangerous as the eyes are never cleaned and tubercle or other diseases may thus be passed from one person to another. And yet there are machines for doing the kissing.

At a meeting of societies caring for the blind, it was said that in one district out of 75 cases of ophthalmia neonatorum notified sight was saved in 61. In 7 it was saved in one eye. Only 2 became permanently blind.

Do you know anything of a quack who calls himself "Dr." Macaura? There is a man here who, under that name, advertises extensively a cure by vibration and sells a machine for applying it. He hires a room in which to display his machine and show its working on patients. It was reported that persons who could not stand up for years were made to walk across the stage by a few minutes' application of the vibrator (?). He has obtained more notice as he seems to have secured the approval of Mr. W. T. Stead, a journalist who has gained rather a curious notoriety. A lady came to see me this week to ask my candid opinion on Macaura's cures and asked me to make experiments with a machine which a friend of hers had bought. She knew Mr. Stead and assured me he was a most sincere and kindly man, though she added, "of course, he has a bee in his bonnet." She read his articles with interest, but admitted they were rather sensational and he seems to have a proclivity toward quackery.

Lt.-Col. A. W. F. Street, D. S. O., of the Indian Medical Service, retired, died on Monday, aged 58. He qualified at the two colleges in 1875-6 and was in the Afghan war of 1878. He was present at the battle of Maiwand and during the defense of Kandahar, being mentioned in dispatches and receiving the medal and clasp. He also served in the

Burmese expedition of 1886 and was again mentioned in dispatches and awarded the medal and clasp. He was further awarded the Distinguished Service Order.

OUR VIENNA LETTER.

(From Our Regular Correspondent.)

SECTION OF POSTERIOR NERVE ROOTS IN TABES—NEW DIAZO REACTION IN THE URINE—MERCURIAL TREATMENT OF TABES DORSALIS—BILHARZIA AFFECTION OF THE BLADDER—606 IN INHERITED SYPHILIS.

VIENNA, January 15, 1911.

IN the Society of Internal Medicine, A. Götzl and L. Moszkowics presented a man in whom, on account of gastric crises, section of the posterior nerve roots had been performed. For six years the patient had suffered from tabes, in which gastric crises predominated. Since the attacks consisted of pain and vomiting of such severity that the patient could eat nothing, the seventh to the ninth dorsal nerve roots of the spinal cord were cut in both sides, these roots bearing the sympathetic fibers that go to the stomach. Following the operation the patient was free from pain, but for the past few weeks slight transient pains were experienced in the meso and hypogastrium (the retained tenth to twelfth nerve roots carrying the sympathetic fibers to the intestines). The vomiting disappeared and the patient took on weight. An anesthetic area resulted in the patient's back, corresponding to the three resected roots. A cutaneous area is innervated by three spinal nerve roots. If only two of these are resected no anesthesia will result. The operation is difficult, and the process of healing in this case was delayed by the gathering of a serous fluid beneath the skin in the neighborhood of the wound. The patient suffered from ataxia and tabetic arthropathy of the right hip.

In the Society of Physicians, Dr. Max Weiss demonstrated a new diazo reaction in the urine. The latter is greatly diluted with water, divided into two portions, and to one are added a few drops of a solution of potassium permanganate, by which the fluid turns yellow. The careful addition of the solution of potassium permanganate intensifies the yellow color. The substance causing the reaction, which is called white urochromogen α, is a precursor of the substance that gives the familiar diazo-reaction; the former is turned into the latter after being kept for twenty-four hours in the incubator. Urochromogen α gives no diazo reaction; only at the end of twenty-four hours does it change to urochromogen β, which gives the reaction. Both chromogens are detected by the permanganate test. Pigments and urobilin in the urine must be precipitated with ammonium sulphate.

Prof. Emil Redlich discussed the mercury treatment of tabes dorsalis. His material consisted of 308 cases, 282 men and 26 women. Of these 43.8 per cent. definitely had had syphilis, 26 per cent. had had an ulcer, a total of 69.8 per cent. Of 39 cases the Wassermann reaction was positive in 70 per cent. Forty-one per cent. of the cases had had no treatment, while in 40 per cent. there had been only a perfunctory treatment of the syphilis. In 18.8 per cent. of the cases there had been a thorough antisyphilitic treatment carried out for one year. The last therefore does not guarantee against the future outbreak of tabes, nevertheless it provides a relative protection. In all initial cases of tabes Redlich administers the mercurial treatment repeatedly, often also in combination with hydrotherapy, and thermal treatment. Eighty-three cases could be followed for a long time. In judging these cases it must be remembered that there is benign as well as malignant tabes. With moderate doses of mercury no harmful results have been observed. He observed one case that remained in the *status quo* for eight years. Even in acute exacerbations he observed improvement and remission of the symptoms for a long time. The mercurial treatment has no effect on a progressive paralysis complicating tabes. In optic atropy there was neither a favorable nor an unfavorable effect. Likewise gastric crises are influenced neither way. Redlich comes to the conclusion that in incipient cases of tabes, and in acute exacerbations, a moderate mercurial treatment is to be resorted to. According to his experience he warns against any optimism regarding Ehrlich's preparation in tabes dorsalis.

Dr. Robert Bachrach treated a fourteen-year-old boy from Cairo, who suffered from a bilharzia affection of the bladder. Cystoscopic examination showed, in addition to diffuse changes of a proliferative cystitis, in one place a suspicion of a papillomatous growth such as is frequently seen in the bilharzia bladder. For this reason, as well as for the increasing difficulties of micturition, a suprapubic cystotomy was performed by Professor Zuckerkandl. Inspection of the bladder revealed a severe cystitis with granular excrescences, but no distinct tumor. After the removal of a piece of the mucous membrane of the bladder for microscopic examination, a suprapubic fistula was left for therapeutic purposes. This was allowed to close spontaneously four weeks later. Bilharzia eggs were found in the urinary sediment and in the vesical mucous membrane. Following the closure of the urinary fistula, the patient was free from difficulties, urinating at normal intervals without pain. Still, the eggs appeared constantly in the urine together with a small admixture of blood. The further history of these patients is a varying one; occasionally, with change of residence and the avoidance of new infection such as results from drinking water, prolonged remissions occur, and only quite seldom complete cure. Frequently, after intervals of six or eight years, there occurs disease of the kidneys or rectal mucosa, with severe and finally fatal changes. In the patient reported by Bachrach the disease was restricted to the bladder. Urine obtained from the ureters through the urinary fistula was free from eggs or other pathological constituents.

Prof. Theodor Escherich has employed the Ehrlich preparation in several cases of hereditary syphilis in children. Six of these were observed for a long time. Of these three died (two being luetic, atrophic children, one of whom succumbed from acute intestinal catarrh). The dose injected was 0.04 to 0.06 gram in an emulsion. In some cases there was a rise of temperature to 103.1° F., persisting for two days, and an infiltration of the gluteal region. Within three to four days after the injection there was an involution of the cutaneous efflorescences, with a disappearance of the spirochetes. Ulcerative processes rapidly healed. In all cases the above doses, as well as one of 0.1 gram, were insufficient for permanent cure; a relapse set in, even in some cases following a second injection. The general condition following injection was considerably improved; in one obstinate case with epiphyseal separation there could be demonstrated after the injection the union of the fragments with

new bony tissue. Three cases were treated by injecting the mother; the injection was well borne, but relapses could not be prevented. One is not yet in a position so to regulate the dose as to completely destroy the syphilitic virus, as the Wassermann reaction in all of the cases remained positive.

OUR LETTER FROM THE PHILIPPINES.

(From Our Regular Correspondent.)

SATISFACTORY HEALTH CONDITIONS—STAFF OF THE PHILIPPINE GENERAL HOSPITAL—HYDROPHOBIA—DISINFECTION AT SAN LAZARO HOSPITAL—PERSONAL.

MANILA, P. I., December 29, 1910.

At the close of the year 1910 the health situation in the Philippines was more satisfactory than at any time since American occupation. There has been no plague even among rodents for over three years; cholera is not known to exist; smallpox exists in almost insignificant numbers in comparison to conditions that formerly prevailed. The death rate of Manila during the last quarter has been lower than in any similar period since 1898. The death rate among Government employees, among whom it is more practicable to enforce sanitary regulations, is lower than for any similar number of people in any other tropical country.

After many delays the staff of the Philippine General Hospital has finally been announced, and is as follows:

The Director of the Hospital is ex-officio Director of Health, Dr. Victor G. Heiser.

Department of Surgery and Gynecology: John Rich McDill, Chief of the Department; Philip Kingsnorth Gilman, Assistant Chief of the Department; Hans E. Schiffbauer, Resident Surgeon; J. W. Smith, Resident Surgeon; Potenciano Guazon, Assistant in Surgery; Jose Edque, Assistant in Surgery; Augusto Villalon, Senior Interne in Surgery.

Department of Medicine: Richard Pearson Strong, Chief of the Department.

Division of Clinical Medicine: William Everett Musgrave, Chief of the Division; Ariston Bautista y Lim; Jose Albert; Donald Gregg, Resident Physician; D. M. Molloy, Resident Physician; Antonio Guillermo Sison, and Dr. Alfonso Raquel.

Division of Tropical Medicine: Richard Pearson Strong, Chief of the Division; Luis Guerrero, David Willetts and Andrew Watson Sellards.

Department of Obstetrics: Dr. Fernando Calderon, Chief of the Department; Baldomero Roxas; Honoria Sison, Assistant Resident in Obstetrics; Cayo Marfori, Assistant in Obstetrics.

Department of Eye, Ear, Nose, and Throat: Major T. C. Lyster, Medical Corps, U. S. Army, Chief of the Department.

Department of Pathology: Under direction of the Bureau of Science; Dr. Paul C. Freer, Chief of the Department.

Training School for Nurses: Eleanor U. Snodgrass, R. N. Superintendent, and Margaret Wheeler, R. N. Assistant Superintendent.

The hospital will be under the immediate management of the Director of Health assisted by an Advisory Board, composed of Doctors R. P. Strong, J. R. McDill, W. E. Musgrave, Fernando Calderon, T. C. Lyster, Ariston Bautista y Lim, Chairman Visiting Staff (ex-officio), Superintendent of the Hospital (Secretary ex-officio).

Since Doctors Dudley and Whitmore have called attention to the fact that hydrophobia prevails in the Philippine Islands and have actually demonstrated cases, the diagnosis of hydrophobia has become increasingly frequent. Arrangements have now been made by the Bureau of Science for preparing the Pasteur treatment and the Bureau of Health has completed arrangements for sending the same to the Provinces.

A new modern steam laundry has just been completed at the San Lazaro Hospital. This laundry is intended primarily for the disinfecting and laundering of all textiles from the dangerous communicable disease hospitals. It consists essentially of a modern steam Kinyoun-Francis disinfecting chamber which opens into a so-called infected room where all the articles are placed in the chamber and after disinfection they are removed from the other end of the chamber which projects directly into the laundry. A small bathing establishment has also been added for the purpose of disinfecting contacts and their clothing.

Dr. A. J. McLaughlin has resigned his position as Assistant Director of Health and Dr. Carrol Fox, Passed Assistant Surgeon, Public Health and Marine Hospital Service, has been appointed in his place.

Report of a Case of the Administration of One-eighth of a Grain of Morphine to a Baby Two and One-half Days Old. N. R. Mason.
Keratosis Follicularis. A. P. Perry.

Sporotrichosis.—R. L. Sutton states that at present in the United States one is interested in the affection more from a practical than from a theoretical viewpoint. The disease is undoubtedly a fairly prevalent one, particularly in the Middle West, and in the majority of instances the true nature of the infecting agent is not recognized because the medical attendant is not familiar with its clinical manifestations. Usually an incorrect diagnosis of syphilis, tuberculosis, or coccic cellulitis is made. When the characteristic symptomatology of the disorder is borne in mind, this mistake is not liable to occur. As the author has pointed out in a previous communication, a traumatic lesion of the arm, forearm, or leg which proves resistant to ordinary surgical treatment, and is accompanied by the development of one or more sharply circumscribed, painless, cutaneous, or subcutaneous abscesses along the course of the limb, should always arouse suspicion, especially if the inflammatory manifestations typical of a streptococcic cellulitis are absent. It is extremely difficult to recover the causative agent directly from the lesions.

Modern Medicine and the Health of Women.—A. C. Vietor states that it appears that, regarding the question of the weakness of the women of to-day, modern medicine finds two great causes at work in their environment: (1) (a) Structural defects in their framework; leading to weakness and inefficiency, to the development of internal weaknesses and dislocations and to a lowering of resistance to infection. (b) Defects in their mental training, leading to lack of balance in mental equilibrium and control, this in turn favoring the development of physical weakness and inefficiency. (2) Infection, especially venereal infection. Taking first the matter of venereal infection. Men must be taught the necessity of avoiding infection; women must be taught the necessity of pro-

tecting themselves from infection; boys and girls must be taught sex hygiene, to the end of eliminating the fountain-head of infection. Taking then the matter of development of the body and the mind, one must realize that it is wrong to educate the growing girl-child's body and mind according to some fancied "feminine" standard; that the ground plan of the body and mind of both the girl and the boy are human in model; that the existence of common muscles and common mental faculties, and their similar response to common stimuli and laws, are indications for common lines of exercise and cultivation; that sex characteristics are secondary and subsidiary to generic characteristics; that sex specialization normally follows upon the establishment of generic growth; and that the individual must be conserved if the race is to be preserved.

Overgrowth of Epiphysis.—J. W. Sever reports a case presenting an apparently idiopathic obliteration of the epiphyseal line, accompanied by a marked overgrowth of the external condyle of the lower end of the femur in a child of eight years.

Breast Abscess During Pregnancy.—J. T. Williams states that 5 5/10 per cent. of all breast abscesses occur during pregnancy. Organisms are present on the nipples in 100 per cent. and in the milk ducts in 86 per cent. of all pregnant women. When their growth is predisposed to by engorgement, or the resistance of the breast tissues is lowered by injury, or the organisms present are of unusual virulence, they attack the tissues and produce inflammation. The prophylaxis of breast abscess during pregnancy consists in absolute cleanliness of the nipple, and the prompt treatment of mastitis by bandage, ice, and saline catharsis.

Morphine Poisoning in a Baby.—N. R. Mason reports a case of an infant two and one-half days old to whom had been administered by mistake one-eighth of a grain of morphine. After prompt and energetic treatment recovery ensued.

Keratosis Follicularis.—A. P. Perry, in reporting a case of this condition notes that it is extremely rare, only twenty-four cases having been recorded.

Fats and Lipoids in Animal Tissue.—J. Wright presents the results of his investigation of the distribution of fat in the cells of the tonsils.

Health Problems in the Philippines.—V. G. Heiser summarizes his article as follows: It is to be understood that the health of these people is the vital question of the islands. To transform them from the weak and feeble race we have found them into the strong, healthy, and enduring people that they may yet become is to lay the foundations for the successful future of the country. But it is not alone the problem of the Bureau of Health. It is an economic and educational question as well. Every branch of the government has its part to perform, and cooperation is essential. Good roads, agricultural improvements, the elimination of rinderpest and other animal diseases, the general development of the country, which will gradually bring about a better standard of living, education, particularly along the lines of hygiene and sanitation, to which we give all the aid possible, but for the dissemination of which we will have to depend upon the teachers and the public schools, the special training of the young men and women of the islands in the professions of medicine and nursing, all the foregoing factors with which we, as a bureau, have nothing to do, are as important to the health conditions of the islands as are the actual holding in check of epidemics and disease, the sanitary inspections, enforcement of regulations, etc., the opening and maintenance of hospitals throughout the islands, and the various other things for which the Bureau of Health is directly responsible.

Iodine as an Antiseptic.—F. T. Woodbury states that iodine has passed the experimental stage as an antiseptic and germicide and that he has discarded all other antiseptics in his surgical practice. He believes that others, and particularly the general practitioner, who try this method will eventually do likewise.

Sarcoma of Submaxillary Gland.—J. D. Whitall reports a case of this condition and comments on the rarity of its occurrence.

Congenital Pyloric Stenosis.—H. Lowenburg reports a case of this condition in an infant seven weeks old, in which recovery followed the performance of a posterior gastroenterostomy.

Otitis and Mastoiditis in Infants.—J. R. Page states that the value of early diagnosis and thorough treatment has been well demonstrated by the results obtained at the Babies' Hospital in that not one persistent discharge of mastoiditis had developed among all those whose drum membranes were incised before rupture occurred. Nevertheless, when mastoiditis has developed and the infection has become established to the point where it resists the most thorough treatment through the canal, the attack on it from behind should be considered before the vitality is additionally lowered by septic absorption. Delay for the appearance of external signs over the mastoid is unwarranted when the character of the discharge, its resistance to treatment, and the general condition of the child is considered. Extensive involvement of the bone with necrosis of the inner plate too often occurs without perforation of the cortex or external signs in even very young babies.

Creosote Inhalations in Pneumonia.—By B. Robinson. See MEDICAL RECORD, February 18, 1911, page 315.

Cysts of the Pancreas.—R. B. Hall states that the diagnosis of pancreatic cyst is more or less obscure and must always be a source of great anxiety to the operator, and, indeed, it is difficult in many cases even after the operation. To confirm the diagnosis, it is necessary, in many cases, to examine the character of the fluid, which, if it is of the pancreas, will reveal the true nature of the cyst. It is a well recognized fact that tumors in the abdomen displace neighboring organs, or become attached to them, thus misleading the operator in his judgment, but, if the contents of the cyst demonstrate the presence of pancreatic fluid, and the anatomical relations are those of a pancreatic cyst, little doubt should remain as to its nature. In a large number of reported cases there is a history more or less definite of an abdominal injury. In many cases the enlargement is observed soon after the injury; in others after a long period of time has elapsed. In other instances the development of the cyst follows some acute illness, such as typhoid fever. The usual course of pancreatic cyst is comparatively acute, a few weeks covering the entire history, but there are a few instances on record in which the cyst has been known to exist for years without causing much inconvenience until some accident to the cyst, like hemorrhage or rupture of the sac, or intestinal obstruction brings the case to a sudden termination.

Tetanus after Vaccination.—B. J. Silverstein reports

two cases of tetanus following vaccination. They are especially interesting as they both followed vaccination within a short period of time, both patients being pupils in the same school. One of these cases was acute, the period of incubation being only four days, the other case was chronic, the period of incubation being two weeks Both cases received tetanus antitoxin and recovered.

Singers' Nodules.—C. J. Koenig states that galvanocauterization of singers' nodules or of polypoid excrescences of the vocal cords appeals to him as preferable and easier of execution than excision with forceps or double curette. It allows an exact localization and limitation of the intervention and the destruction of just what is necessary and nothing more, a very important desideratum for a singer.

Surgical Diseases of the Umbilicus.—By T. S. Cullen. See MEDICAL RECORD, Vol. 77, page 1070.

Bile-duct Implantation.—By R. C. Coffey. See MEDICAL RECORD, Vol. 77, page 1100.

Carcinoma of the Cecum.—J. Frank reports a case of cecal carcinoma involving also the appendix and adjacent glands. The macroscopic examination was made by laparotomy. The mass was removed with resection of three inches of the ileum and about six inches of the ascending colon, the cut ends being inverted and closed as in appendicitis. The anastomosis was made by the lateral method and the wound drained with gauze and gutta percha. A fecal fistula developed from the inverted ileum on the tenth day after the operation, but closed at the end of the fourth week. With this exception the recovery and convalescence were uneventful. Microscopic examination showed the growth to be an adenocarcinoma, but it was not possible to state whether its origin was in the cecum or in the appendix.

Electric Centrifuge.—A. S. Brumbaugh describes his method of converting an ordinary electric fan into a centrifuge.

Salvarsan in Children.—L. Fischer states that from a study of his experience the following deductions are justified: First, the toxicity may be due to a hypersensitive body, possibly an idiosyncrasy. Second, the dose of the drug (0.3 gram) is too large for children, and hereafter he will advise no more than 0.1 gram of the Ehrlich-Hata preparation, the dose not to be repeated for at least several weeks, or until one is justified in assuming that there are no systemic symptoms associated with the first dose. From his present experience he would strongly advise against the injection of ambulant patients, but would require the injection to be given either in the hospital or in a sanatorium, where proper medical supervision and competent nurses can supervise details and note toxic symptoms as early as possible.

Life and Health as National Assets.—F. F. Wesbrook states that one cannot disassociate the conservation of health and life from that of our other national resources, and he points out the failures and difficulties of the past and the reasons why the fact has been so little appreciated up to date. Disease is a manifestation of life that is capable of modification, prevention, or cure by human agency; and even death may be postponed by the same means. The national annual loss from neglect of these matters in the way of preventable disease and death has been estimated as high as a billion dollars annually. Public apathy in regard to the subject must be overcome. Private effort alone is too often inefficient. Law has to follow public opinion and the public is not yet fully educated as to its needs, though at the present time the public press and other publications, government and private, are overflowing with information on the subject. What Americans can do when supported by authority in the way of eradicating disease has been shown in the tropical dependencies. At home we have the brains to do the work, we have not yet learned to delegate the authority and pay the bills. The individual is willing to pay for his cure when he is sick, and communities pay the costs of epidemics, but what they seem to want is a cure, not protection.

Picric Acid and Burns.—A. Ehrenfried concludes that the saturated aqueous solution of picric acid is incontestably superior to any other antiseptic surgical dressing at one's disposal for the treatment of superficial wounds and lesions in which the rete Malpighii of the skin is not completely destroyed—particularly in first and second degree burns. It is cheap and simple in application and induces rapid regeneration of the skin without pain or irritation. Deeper lesions may be made to heal by the formation of a smooth, level, non-secreting granulating surface, over which dermatization will proceed rapidly, or which will serve as an ideal base for the reception of Reverdin or Thiersch grafts. The mild toxic symptoms which have been reported as occasionally occurring will never be seen if reasonable care is exercised.

Colitis.—G. D. Kahlo remarks that the confusion in the conception of colitis by different physicians is not surprising, considering its protean characteristics. As generally used the term includes both conditions associated with catarrhal inflammation and those in which the disturbance is dependent on a secretory neurosis. He has excluded, however, the acute forms, those complicating gastric and enteric troubles and all other conditions in which the colonic involvement seems secondary. The most frequent symptom in the author's cases was a disagreeable sensation in the abdomen, not amounting to actual pain. Among other symptoms mentioned are gastric distention, eructations, regurgitation, coated tongue, a bad taste in the mouth. Nausea was less common. Cardiac palpitation and vertigo, insomnia, migraine, neuralgia, mental depression are all probably neurotic or the result of autointoxication, which he thinks was the chief cause, as these symptoms usually disappeared when the digestive disturbance was corrected. Diagnosis of typical cases is easy, but mistakes were frequently observed and the author thinks that there would be fewer operations for gall-stone and appendicitis if more care were used in diagnosis. Fecal examinations are important but must be used like all laboratory work in connection with clinical symptoms. Gastric complications were most common and examination of stomach contents is often of value in the diagnosis. Appendicitis and cholelithiasis were observed in a number of cases. Gouty manifestations and skin complications were very common. The treatment varies according to the indications and the causal influences, but it cannot succeed with medicine alone. There is no scheme of diet applicable in all cases. The author speaks of the milder mineral waters of the alkaline saline group as among the most useful remedies. Exercises and abdominal massage are mentioned as having their proper place in the treatment. There are few conditions in which the psychic element enters more largely into the treatment but he does

not think highly of colostomy as a surgical measure and its advantages are more than offset by the depressing effect of the operation and the presence of a fistulous tract to be closed up afterward. The prognosis is as a rule favorable though improvement may be slow.

Mammary and Dermal Leukemia.—C. Dencker reports a case of leukemia in a woman presenting some rare features, such as lymphatic infiltration of the lips, nose, and pinna, and a most remarkable involvement of the mammary glands, which he has been unable to find described in the literature. The trouble began with itching of the nose, followed by redness and swelling of the nose and lips, diagnosed by various physicians as cold and eczema, and so treated. The patient's previous health had been good. All the superficial lymph glands of the body were enlarged more or less, the least in the neck glands. The breasts were symmetrically enlarged, firm, and infiltrated. The bloodcount showed 110,000 white cells, 82 per cent. small and 6 per cent. large lymphocytes and a moderate secondary anemia. The patient suffered much discomfort from dyspnea and tracheotomy was not thought advisable. Necropsy showed the usual lesions of ordinary lymphatic leukemia, lymphoid infiltration of the viscera and of the skin of the nose and lips. The mammary glands were replaced by a mass of lymphoid tissue of uniform consistence, the normal tissue having disappeared almost entirely.

Stain for Bacterial Capsule.—E. C. Rosenow describes his new method of staining bacterial capsules. It has proved of value in a study of autolysis of pneumococci, in their identification in culture and exudates as well as in staining the capsule of *Streptococcus mucosus* and, with a slight modification, the capsule of the *Bacillus mucosus* also.

A Case of Anaphylaxis.—A. E. Taylor reports the case of a physician in San Francisco who performed an autopsy on the first white case of plague that occurred there in the year of 1900-01. After the definite diagnosis of the case as one of plague it was thought advisable to give an injection of the Yersin serum since no precaution had been used in making the autopsy. Four years later, while hunting in the mountains, the physician had trouble in loading a horse with a deer that had been shot and had his hand badly scratched and lacerated by the metal parts of the harness. On his return home a few days later, not being satisfied with the condition of the wounds, he had them thoroughly cleansed and disinfected and received an injection of 20 c.c. of antitetanic serum. After a few hours he was suddenly seized with an attack of giant urticaria, with great swelling and almost intolerable itching, tachycardia, and choleric diarrhea lasting three days. On the third day a neuritis developed in the circumflex nerve, followed by wasting of muscles, degeneration reaction and cutaneous anesthesia, the recovery from which has not yet been complete. There was great prostration, due perhaps to the diarrhea. The patient had never had any asthmatic trouble or been in the least "sensitive" to horses, and the case has all the features of an experimental anaphylaxis. As such it is deemed worthy of publication.

Air Embolus.—E. G. Mark describes a case of air embolism occurring during an operation under air inflation urethroscopy.

Change of Voice.—E. B. Scripture gives the treatment of the improperly developed or eunuchoid masculine voice. He says that examination of the larynx in such cases shows the vocal cords to be very shiny and white and apparently very tightly stretched. External examination shows that in speaking or singing the larynx is pulled high up under the tongue and often rather forward toward the chin. The condition is evidently due to an overcontraction of both the intrinsic and extrinsic muscles around the larnyx, causing overtension of the vocal cords. It is a purely nervous habit. The treatment begins by teaching the person to sing on very low tones. These will at first be harsh and rattling, but will soon become natural. The pitch of the song is gradually raised until the patient sings over the normal range of voice. Another exercise consists in chanting sentences on a single low tone, gradually raised in pitch in successive exercises. A third exercise consists in singing the first word or two of a sentence on a low tone and finishing it by speaking. Exercises in singing and speaking are used with the larynx pressed downward and backward. A cure is generally accomplished in one or two weeks.

Color Vision and Color Blindness.—F. W. Eldridge-Green presents the following theory of color vision and color blindness: A ray of light impinging on the retina liberates the visual purple from the rods and a photograph is formed. The rods are concerned only with the formation and distribution of the visual purple, not with the conveyance of light impulses to the brain. The ends of the cones are stimulated through the photochemical decomposition of the visual purple by light (very probably through the electricity which is produced), and a visual impulse is set up which is conveyed through the optic nerve fibers to the brain. The character of the stimulus differs according to the wave-length of the light causing it. In the impulse itself we have the physiological basis of the sensation of light, and in the quality of the impulse the physiological basis of the sensation of color. The impulse being conveyed along the optic nerve to the brain stimulates the visual center, causing a sensation of light, and then passing on to the color-perceiving center cause a sensation of color. But though the impulses vary in character according to the wave-length of the light causing them, the retinocerebral apparatus is not able to discriminate between the character of adjacent stimuli, not being sufficiently developed for the purpose. At most seven distinct colors are seen, while others see in proportion to the development of their color-perceiving centers only six, five, four, three, or two. This causes color-blindness, the person seeing only two or three colors instead of the normal six, putting colors together as alike which are seen by the normal-sighted to be different. In the degree of color blindness just preceding total only the colors at the extremes of the spectrum are recognized as different, the remainder of the spectrum appearing grey. Though the author's own opinion is that the ordinary form of congenital color blindness is caused by a defective development of the portion of the brain whose function is the perception of color one must not exclude any portion of the retinocerebral apparatus, defect of which would have exactly the same result.

The Position of Sir Charles Bell Among Anatomists.—A. Keith states that, on whatever standard one proceeds to judge, Charles Bell must be assigned a first place among the world's anatomists. He did for the anatomy of the nervous system what Harvey did for the circulatory system—brought order out of chaos.

Treatment of Extensive Caries in Children.—J. F. Colyer states that for several years it has been his practice to treat extensive caries in children by extraction. The principal criticisms brought against this method of

treatment have been: (1) that the loss of mastication area interferes with the growth of the child; and (2) that the effect on the permanent series is to cause irregular eruption and crowding of the teeth. The author shows that these criticisms are not altogether supported by facts, and that the effect of the removal of the teeth on the general health of the child is beneficial rather than harmful; still further, that the harm accruing to the permanent series is slight and well outweighed by the gain to general health. The treatment, briefly stated, consists in the removal of all functionless deciduous and permanent teeth.

X-Bodies in Human Blood.—A. Balfour states that these bodies had once been noted in the blood of a sick dog in Khartoum. He also detected them in the blood of a female patient who for four months had been suffering from a peculiar urticaria, the wheals appearing every evening and disappearing at sunrise, a condition which the author terms "urticaria nocturna." In the blood of this patient there were found typical X-bodies in considerable numbers, free and occasionally lying in the red cells. A fairly common form was the small body which Horrocks and Howell describe as being about one-eighth the size of a red corpuscle, spherical in form, and consisting of a faint capsule with a circular center staining deep blue. The majority, however, had centers more of a pale lilac than a blue color, and contained faintly staining material between their capsules and their centers. What may be called large and intermediate forms of a similar type were present, but in the former the capsule was not so defined, the appearance being rather that of a halo of more faintly staining substance surrounding a deeply stained spherical core.

Hyperemia Treatment of Fractures.—A. E. Barker concludes that it may be accepted as fairly certain that, excepting the interposition of fragments of detached bone, of muscles or tendons, or of stripping of periosteum, the chief cause of delayed or completely arrested union of fractured bones is lack of proper circulation in the area injured. This may be due to rupture of the arteries supplying the bones, to over-tight bandages when the splints are applied, or, above all, to disuse. If the vascular supply is damaged it is plain that one cannot repair the condition. But one can further impair the proper blood supply by improper bandaging. This is avoidable. As to disuse, as long as the fracture is insecure it is difficult to make any use of the muscles of the limb. If one could it is probable that such fractures would rarely fail to unite. It is known that broken ribs, which are always in a state of movement, hardly ever remain ununited. When then, for any of the last causes mentioned, repair has not taken place, it is natural to turn to mechanical measures to increase the hyperemia of the parts involved. In the past this has been done, either by forcibly rubbing the fractured ends together to excite a fresh traumatic hyperemia, or by pegging the bones with ivory nails, or by massage. These measures have succeeded in many cases and failed in others, in the last case often on account of suppuration. It is only claimed for the elastic bandage that it produces a greater vascularity of all the parts involved easily and without risk if properly done. The question how long it should be kept up is variously answered. In the author's experience all the effects desired have been obtained by the use of the bandage for about two hours, morning and evening.

Treatment of Skin Diseases by Hyperemia.—W. K. Sibley states that from his observations he has formed the opinion that practically all chronic forms of skin diseases are benefited by the hyperemic treatment before applying local remedies. The action of ointments and lotions is considerably facilitated if a local congestion of the part is produced before they are applied. This local hyperemia probably acts in two ways. In the first place, by producing a passive congestion it increases the blood supply and so improves the nutrition of the part and at the same time encourages the removal of deleterious products by the venous blood. In the second place, this local hyperemia assists in the local action of the drugs when they are afterwards applied. Of the cases so far treated, it would appear that the most satisfactory results have been obtained in psoriasis, especially in some very old-standing cases in which the lesions were very chronic and localized. There are cases of this complaint of many years' standing where some very persistent lesions are limited to a small area, such as the knees or elbows, and which resist all treatment. This is the class of case specially benefited by this method. Some cases of lupus vulgaris have shown rapid improvement—in fact, from some recent observations the hyperemic method showed earlier and much more satisfactory results that the *x*-rays had done. Acne, both diffuse and local, reacted well, but these cases required a considerably greater amount of congestion and more frequently repeated treatments, both general to a large affected area, and afterwards local to the individual and more persistent comedones and pustules. The immediate result of the local treatment is to produce a venous congestion of the skin, which increases the action of the sudoriferous glands, and gives rise to a varying degree of perspiration. This varies with the nature of the lesion and the degree of hyperemia produced. In some conditions only an almost imperceptible amount of sweating results—perhaps just sufficient to produce a slight haziness on the sides of the cupping glass without a visible sweat on the skin. In others, such as many eczemas and seborrheas, a profuse perspiration is quickly produced, and after a few minutes the whole part is bathed in sweat. In other cases the ordinary sweat is replaced by a serous exudation. In some instances of nonulcerated lupus, which as a class perspire very freely under the treatment, a blood-stained serum exuded after a short time, and for this reason the cases require to be very carefully treated and only for very short periods at a time, one minute or so being usually sufficient.

Magnesium Sulphate in the Treatment of Erysipelas.—K. B. N. H. Chosky reports four cases which generally bear out all that has been claimed for this form of treatment. In almost every instance the immediate effects of the application of magnesium sulphate solution were extremely beneficial. Pain and swelling abated, fever decreased, and extension of the infection was controlled in the majority of cases. The results, however, have not been so uniformly good as those described by others, inasmuch as advanced and neglected cases, as also cases of the graver type, so largely prevailed. In six cases, for example, the inflammatory process extended so rapidly in spite of this treatment that antistreptococcus serum had to be injected, but only one of them recovered. The quantity injected varied from 60 c.c. to 280 c.c. Excluding the above and the seven moribund cases there remained 59 cases with 13 deaths and 46 recoveries, equivalent to a case mortality rate of 22 per cent.

Organization in the Profession.—W. Osler states that the medical society may do three things. It is the most important single factor in the promotion of that unity and goodfellowship which add so much to the dignity

of the profession. Its second great function is postgraduate instruction. To each member it should be a sort of clearing house of his clinical experience. The third equally important function of the medical society is the support of a library. The county hospital may play an important rôle in postgraduate instruction. The author refers to the scheme which was discussed at the last International Medical Congress at Budapest, under the chairmanship of Professor Waldeyer. An International Committee has been formed for the promotion of postgraduate study. The idea is to have in different centers medical extension courses, which will enable physicians to supplement their knowledge without making heavy material sacrifices. In large towns and cities scientific centers are to be formed as places of instruction, in which the hospitals on the spot should be made use of, and the physicians capable of teaching should act as instructors. Already in Germany, according to Professor Kutner's recent report, extension courses have been organized in more than fifty centers. The postgraduate courses could be arranged to meet the new demands; for example, in school inspection they could be coordinated with the various schemess of social economics at present before the community—child-saving, social purity, etc. The county hospitals furnish the machinery to carry out this work; but before it could be properly organized certain changes are essential. Money must be spent on the development of the scientific departments which are nowadays essential for the treatment of patients and the study of disease. Every county hospital should have a good pathological laboratory; a clinical laboratory, with its bacteriological, chemical, and physical departments. The new developments in bacteriological and in vaccine treatment render it imperative that all this work should be done in the hospital itself, and by men who have had thorough training. In this way an institution may extend its benefits to the praceice of every doctor in the county who looks to it for the opportunities to continue his education, and who should regard it as his chief adviser in all difficulties and worries. An increasing number of practitioners recognize that the home clinical laboratory is just as important as the dispensary, and for such men it is invaluable to be within easy reach of skilled advice.

Anatomy in Clinical Surgery.—C. B. Lockwood emphasizes the importance of anatomy as the foundation of all surgery.

Radium in Gout and Rheumatism.—Professor William His states that radium or some of its derivatives forms a constituent of certain natural curative springs, the action of which medical men have not been able to explain satisfactorily. Dautwitz was the first to treat various pathological conditions with baths to which uranium pitch ore, containing radium, had been added. The author investigated the therapeutic value of the substance in the case of 200 patients observed at the Charité and in private clinics. Of the 100 cases of chronic rheumatism, 47 were improved, 20 were considerably improved, 5 nearly cured, 13 were uninfluenced by the treatment, and the result was not apparent in 6. The best results may be expected in diseases which have not existed for too long a time, and in which the chief changes are swelling and infiltration of the capsule of the joint. This form, which most frequently affects women either at an early age or about the time of the menopause, constitutes the larger contingent of the considerably improved. In the next place, the dry form, in which the capsule remains unaltered for a long time, while the cartilage is markedly degenerated and the muscles almost always affected, yields very favorable results, in so far as the pain is diminished, the muscular contractures lessened, and the motility increased. The results in gout are much more striking. The author was able to observe and treat 28 patients for a considerable period. Of these, 4 remained unaffected, while in 24 a marked improvement in the condition was achieved. Some of the patients have stated that they have remained free from symptoms for a year after the termination of the treatment. It has been proved that the active agent is not radium itself but the emanation which radium produces. The most active application of emanation is achieved when the individual is breathing an atmosphere which contains a certain quantity of radium emanation. For producing the latter various "emanators" have been invented. A stream of oxygen bubbles through a fluid containing a salt of radium and is saturated with emanation. The emanation issuing from the fluid is distributed equally in the air of the room by a ventilator. This method, however, has the disadvantage that it can only be applied when a special emanator is available. For this reason portable inhalation apparatus has been constructed, in which the emanation is liberated from its solution by a stream of air produced by a hand bellows. The air containing the emanation is then breathed. After a few strokes of the bellows the emanation is completely driven off from the water, and a considerable time is required before equilibrium is again established between the insoluble radium salt and the emanation in solution. The effects of radium emanations on processes taking place in the body have been found to be as follows: The inflammatory migration of leucocytes is completely arrested. Ferments are activated. In addition to the autolytic action, the action of inhibiting inflammation, and that of alleviating pain, which are effected in the treatment of rheumatism, there is in the treatment of gout a specific action which is directed to the uric acid and its salts, and to the processes of metabolism regulating the quantity of uric acid in the body. This ensures a greater certainty of action.

Right-sided Pleural Effusion.—A. C. Geddes states that as a result of the consideration of certain cases now and formerly described he is confirmed in his opinion that one cause of sudden death in cases of right-sided pleural effusion may well be occlusion of the great veins as they approach the heart, and more especially occlusion of the inferior vena cava. The suggestion is not a new one, although it has not received general acceptance at the hands of the physicians.

Treatment of Nevi by Freezing.—J. L. Bunch states that excellent as are some of the final results of treating nevi by means of radium, the method is, nevertheless, far from rapid and is beyond the means of many patients. For nevi in certain positions, such as those of the eyelids which involve the conjunctiva, radium has perhaps some advantages over other methods of treatment, and will still be used; but in the vast majority of cases equally good results can be obtained far more quickly, certainly, and cheaply by the application of solid carbon dioxide. Where the nevus is superficial a single application for a few seconds will effect a cure, and the resulting scar is so inconspicuous that it is difficult even to detect.

Gastric Cancer in a Youth.—J. R. C. Carmey reports a case occuring in a boy aged 19 years in whom a definite diagnosis was not made until after death. The reason for this was that, although the symptoms and signs were on the whole those usually associated with malignant disease of the stomach, owing to the patient's youth he was at first thought to be suffering from abdominal tuberculosis. Toward the end of his illness, however, it was suspected that something more serious than an inflammatory condition was present in order to produce such urgent symptoms.

Yellow Fever in West Africa.—Sir Rubert Boyce continues his history of yellow fever in West Africa.

High Temperature after Labor.—G. H. Fink states

that experience has shown that the salicine group of drugs is a very safe and sure remedy in the majority of cases of high temperature after labor, and the earlier they are used in the treatment, the better for the patient.

Berliner medizinische Wochenschrift.

January 30, 1911.

Mydriatic Action of Organ-Extracts and Fluids.—Catapano starts with the discovery of Meltzer of the mydriatic action of adrenalin on the enucleated frog's eye. Later Schurr and Wieser found that the serum and urine of nephritics possess the same power. Cramer next learned that the hypophysis (glandular) substance exerts the same influence on the frog's eye. The question naturally arises, does this action occur from the extracts of other organs and what is its limitations? After having corroborated all the findings above given the author tested thyroid extract and found that its aqueous extract possesses no mydriatic action. Thymus extract exerted a very slight activity in this direction. Spleen extract was inert in this respect, but the extracts of liver, kidney, and pancreas acted positively. A better idea of the author's work appears from his summary. The adrenals and hypophysis, both in aqueous and alcoholic extracts, possess a distinct and intense mydriatic action. Other parenchymatous organs, including the genital glands, give but a feeble, positive result, as does also muscle extract. The extracts of brain and spleen are completely inert, and this is true of the aqueous action of thyroid, although the alcohol extract was later found to possess a weak mydriatic power. The author found that, since blood serum (except of nephritics) does not possess mydriatic activity, the active principles reside and remain in the organs themselves. They are soluble in water and alcohol, and since the reactions occur without reference to temperature, they are not due to enzymes. We know little of the nature of this action, but its occurrence in nephritis and uremia—the serum and urine then becoming mydriatic—is doubtless due to consecutive stimulation of the adjacent adrenals; perhaps also from interference with elimination.

A New Infectious Disease of the Conjunctiva.—Leber and Prowazek refer to a form of conjunctival disease known to have existed for at least thirty years in the Samoan Islands, but new to the world of exact science. The authors term the affection "epitheliosis desquamativa conjunctivæ." They confine themselves largely to demonstrating that while the affection has many points which suggest trachoma—chiefly the contagion and the morphological appearances under the microscope—it cannot be trachoma. All inclusions are present which are usually, but by no means invariably, distinguishable from those of the domestic scourge. It is a protozoan disease, but readily subject to mixed infection with bacteria. Clinically it asserts itself first as a palpebral conjunctivitis having a milky secretion. A sort of initial focus may be seen at the very outset, from which the affliction spreads. The grade of inflammation is a low one, desquamation being the chief feature. The mucosa then hypertrophies, although folliculosis is rare, the swollen membrane having usually a velvety surface. The third stage is one of smooth atrophy. The cornea is not implicated, at least at the outset, and the implication is only sympathetic or terminal. We note no mention as to whether true trachoma occurs in the Samoan Islands, nor, if this be the case, whether mixture of infection has been observed. The Samoan disease would seem to be far more amenable by nature to treatment and prophylaxis. Pyoktanin (1 to 100, 1 to 1000) is of value in the earlier stages, and perhaps as a prophylactic. Adrenalin is of value. The later manifestations of the disease are not specific, but such as may follow any severe affection of the conjunctiva, and are to be looked on as non-essential sequelæ. Hence no new measures are indicated, but simply those in vogue for pterygium, symblepharon, etc. Blindness is not mentioned. The author suggests that this affection may be present in many South Sea Islands, and even among the aborigines of New Zealand.

Origin of the Ascites in Hepatic Cirrhosis.—Klopstock, who has been writing a serial article on hepatic cirrhosis, evidently does not regard ascites as a simple obstructive phenomenon, for it is often absent when it ought to be in evidence. The old view of the preventive power of an augmented collateral circulation seems to be in doubt. There are two types of ordinary or, say, alcoholic, cirrhosis in which ascites is present or absent respectively. Obstruction is not the main factor, for stasis in the portal vein with attempts at compensatory circulation may be present or absent in either type. Believing that cirrhosis is a toxi-infectious disease, the author regards the presence or absence of a quasi ascites as due entirely to the presence or absence of peritoneal complications due to the original bacterial cause. The fluid of hepatic ascites, so-called, has rather a peritoneal cell count than one due to simple stagnation. The author's views might be borne out in part by the lesions found in the so-called Bamberger's disease, in which chronic peritonitis and hepatic lesions coexist, but he does not even allude to the latter affection by title. He does mention coincidental conditions in malaria, syphilis, Banti's disease, and miscellaneous unknown affections.

Münchener medizinische Wochenschrift.

January 31, 1911.

Arterial Rigidity in Childhood.—This interesting subject, through its supposed bearing on precocious senility, is covered very briefly by Hamburger. For the past five years he has studied children aged from seven upward, and has found over and over a rigidity of the radial and temporal arteries in apparently healthy children which, however, is not necessarily permanent. When these superficial arteries are palpable there should be abnormal tension of the brachial and carotid, although without added resistance to compression. We have here a hypertonus of the arterial musculature, a phenomenon previously noted only by Krehl, and by him in adolescents. Aside from this rigidity of the arteries themselves, increased arterial tonus is not uncommon in children between eight and fourteen years of age, and not infrequently leads to suspicion of arteriosclerosis or nephritis. Further study of the types of children who present these phenomena shows the frequent coincidence of nervousness or neurasthenia. Migraine and cardiac palpitation often coexist, as does the entire picture of vasomotor irritability (blushing, cold, and perspiring extremities, desmographism, etc.). The occurrence of these phenomena during the school years is suggestive. The author will elaborate this subject in a second paper.

Salvarsan in Pemphigus Syphiliticus Neonatorum.—According to Baisch, salvarsan has shown its superiority to older remedies in having effected a cure in the so-called malignant syphilitic pemphigus in the newly-born. It has usually been impossible to perform mercurial inunctions in these cases, in which nearly the entire surface is strewn thickly with purulent bullæ, while the internal administration of mercury produces no impression on the march of the disease. While it has been claimed by some of the founders of the treatment by salvarsan that the nursing months furnish more or less of a contraindication, no such rule holds good for pemphigus neonatorum. Even in the first week the author would not only give a relatively large dose, but would repeat it, 0.15 at each injection. Previous to using salvarsan he had a record of thirteen consecutive deaths and no re-

coveries. This series includes the spirochete period, and as the pus of the bullæ always contained the parasite there could be no doubt as to diagnosis. It must be conceded that these cases are usually prematures, so that the chances of survival are weakened. In the successful case of the author, in which the success was attributed to salvarsan, it is to be noted that the child was born at full term.

Stroganoff's Treatment of Eclampsia.—Roth states that Stroganoff has now treated 400 cases of eclampsia by his so-called prophylactic method. The chief interest in the latter is that it does not appear to depend at all on the autotoxic theory of the disease. Roth himself has personal notes of fifty cases treated at the Dresden clinic by the method in question. The treatment consists essentially in controlling the convulsions by a somewhat complicated technique. Morphine, chloral, and chloroform are all used. Everything is done to diminish external irritation of the special senses. The second resource is rapid —at times forced—extraction of the child during the chloroform narcosis. As Stroganoff's treatment is recorded in some textbooks, it is unnecessary to do more than deal with Roth's personal experience. The author lost but four of his fifty mothers (8 per cent.). One decedent had organic disease of the heart and kidneys, while the others were due to aspiration pneumonia. The three in question may be ascribed for the sake of argument to the narcosis. But if we leave out the first decedent the maternal mortality sinks to 6 per cent. The infantile mortality was but 18.6 per cent., a surprisingly favorable result. *Accouchement forcé* was not necessary in a single case.

Deutsche medizinische Wochenschrift.

January 31, 1911.

Thyreotoxic Symptoms Following Iodine Medication.—Wolfsohn first refers to the great amount of iodides used throughout the world and states that we need a more exact degree of knowledge of their activities in the body. We have one series of phenomena known collectively as iodism, but there is another syndrome which sometimes follows the use of minimal doses and has no connection with iodism, since the latter results simply from pushing the remedy to the point of tolerance. The second syndrome referred to is of the nature of a hyperthyroidism, a sort of artificial Graves' disease. Kocher announced the discovery long ago that goiter patients were often intolerant of small doses of iodine. It is certainly much more common in the goitrous than in healthy individuals. The author relates a case of suspected syphilis in which iodide of potassium not only caused the general Graves' syndrome, but a swelling of the thyroid. The same results have followed minimal absorption of iodoform and its derivatives. Such cases may be termed supersensitive to iodine. Analogous are some of the results of thyroid medication, usually attributed to thyreotoxins, but due perhaps to the iodine content. We see here a variety of conditions blending into one another—the supersensitiveness of goiter patients, of non-goitrous patients, the confusion between iodine anaphylaxis and a thyreotoxicosis. That a true iodine anaphylaxis exists is shown by its transmissibility to guinea pigs. In such cases the temporary swelling of the thyroid is a consequence and not a cause. It is this feature that the author really deals with, for the supersensitiveness of the goitrous patient must in some way be dependent upon the supersensitiveness of the normal subject. The action of minute doses of iodides in Graves' disease should be thoroughly studied. In the meantime, whenever we give iodine derivatives, locally or inwardly, we should watch for iodine anaphylaxis, which is a manifest contraindication.

Cholera Vibriones in the Danube.—Strösznер appears to have shown beyond all doubt that the cholera vibrio exists both in the water of the Danube and in the ooze of the river bed. It is also evident that it can survive the winters. The author makes no mention of local epidemics from the river in question, but he does cite a sporadic case which occurred last September in Budapest and which we may readily believe would have passed for cholera nostras or some other severe enteric malady, had not a special research been made for cholera. The number of vibriones in the river is probably small, so that an epidemic is not favored. Exposure to the germ is also not likely, for it may lie principally in the river bed or be swept about in currents. The presence of the vibrio is a menace and everything should be done by means of signs, etc., to warn the public as to the risk they run in making use of the river water.

Transmissible (?) Diabetes.—Langaker relates a remarkable episode in which five out of seven children of a family, aged from 4 to 11 years, died of diabetes within four years, one case following another. Such histories are common in tuberculous families and no one questions the transmission of the disease from member to member; and it would seem at first sight that nothing but transmission could explain the cases under consideration. The stock was a sound one, the parents in good health, and the surroundings hygienic. The author makes no mention of any similar case in literature. Conjugal diabetes occurs now and then and suggests a possible transmission. It does not appear even that the diabetes in these cases was of a uniform type. One case was accompanied by degeneration of the pancreas, but in another this could not be affirmed. There seem to have been but two autopsies. The case appears to have been an example of familial disease in the narrower sense of the term, *i.e.* confined to the children of one family, the parents remaining immune. Many diseases have been placed on record which assumed this form, *i.e.* that of "unifamilial childship." When disease supposedly non-transmissible appears in this quasi contagious or infectious form we are forced to think of the doctrines of Mendel and de Vries as to the sudden appearance of new types and the mutation of species.

Topography of Pulmonary Localizations in Pneumonia of Children.—E. Weill and G. Mouriquand have examined 240 cases of pneumonia in children with reference to the formation of a triangle of hepatization, and have been impressed with the frequency with which the pneumococcus attacks certain portions of the lungs. The most frequent localizations of consolidation are the left base and right apex. Out of the 240 cases 200 were distinctly localized; of these 82 involved the left base; 64 the right apex; 32 the right base; 15 the left apex. Radioscopy shows with especial plainness the localization at the apices. Here develops a triangle of hepatization with its base in the axilla and apex at the hilum of the lung. It is quite superficial and cannot easily be recognized by the stethoscope. In 32 cases examined radioscopically it was demonstrated in 26.—*Annales de Médecine et Chirurgie Infantiles.*

Contribution to the Study of Anaphylaxis.—Ugo Calcatura says that the factors necessary to cause anaphylaxis are a first dose of any infection or serum, a period of incubation sufficient to allow of hypersensitiveness being developed, and a second dose of the infection, which brings about the phenomena of anaphylaxis. The period of incubation is generally from ten to twelve days. Many disturbances referred to idiosyncrasy may have this as a cause. The intolerance of infants for cow's milk may be due to this phenomenon. Deaths from the use of sera may also be due to anaphylaxis. The author made experiments as to the effects of diphtheria antitoxin on the nervous system when injected into the spinal canal, with the view of reaching the nervous system more directly in cases of paralysis. In two such cases the injection caused symptoms of anaphylaxis to appear, while in several others none was produced. The author concludes that in cases of diphtheria we should exercise the greatest care in the use of second injections after some days have elapsed from the use of the first dose of serum. —*Rivista di Clinica Pediatrica.*

Book Reviews.

Salvarsan or 606 (Dioxy-Diamido-Arsenobenzol). Its Chemistry, Pharmacy and Therapeutics. By W. Harrison Martindale, Ph.D. Marburg, F.C.S., and W. Wynn Westcott, M.B. Lond., D.P.H., H. M.'s Coroner for North-East London. $1.50. New York: Paul B. Hoeber, 1911.

This book gives a full account of the history, chemistry, and therapeutic uses of salvarsan. The various methods of injecting the drug are described, along with the apparatus needed. In considering the dose, the average, highest, and toxic doses are given. Mention is also made of when it may be considered safe to repeat the injection, the after effects, the effects on the general health, the untoward results and the contraindications. The book will certainly prove of value to anyone who contemplates using this remedy.

Lectures on Surgical Nursing. By E. Stanmore Bishop, F.R.C.S., Eng., Honorary Surgeon Ancoats Hospital, and Gynecological Surgeon Jewish Memorial Hospital, Manchester; Member of Council Obstetrical Section, Royal Society of Medicine. Author of "Uterine Fibromyomata" and "Pelvic Diagnosis." Illustrated. New York: William Wood & Company, 1910.

This admirable little volume consists of a series of twelve lectures, which aim to provide the surgical nurse with the reasons for the multitudinous details of her work, so that she can intelligently modify her actions according to the necessities which may arise. The topics of the respective lectures are as follows: history of antisepsis and asepsis; methods of sterilization; altruism; position of the patient; chart-taking; baths; examination of urine, feces and gastric contents; dressing of wounds; preparation of patient for operation; duties of nurses in the theater; duties of nurse during recovery of patient from anesthetization; and preparation for operation in a private house. One notes the comprehensive manner in which the entire ground of surgical nursing is covered, including the ethical and sentimental phases of the work so lucidly presented in the chapter on altruism. The language is eminently clear and free from unnecessary technicality. This book may be recommended as an excellent text-book on a subject that has undergone so many recent developments.

The Practical Medicine Series. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology Chicago Post-Graduate Medical School. Charles L. Mix, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. Series 1910. Chicago: The Year-Book Publishers.

Volume V. Obstetrics. Edited by Joseph B. DeLee, A.M., M.D., Professor of Obstetrics, Northwestern University Medical School. With the Collaboration of Herbert M. Stone, M.D.

Volume VI. General Medicine. Edited by Frank Billings, M.S., M.D., Head of the Medical Department and Dean of the Faculty of Rush Medical College, Chicago, and J. H. Salisbury, A.M., M.D., Professor of Medicine, Chicago Clinical School.

Volume V of this series is a review of the work done in obstetrics during the past year. It is divided into four parts, dealing respectively with pregnancy, labor, the puerperium, and the new-born. The first chapter opens with statistics of pregnancy and labor occurring in girls under thirteen years of age. The statistics are given to show that young primiparæ seldom meet with dystocia or accidents in their deliveries. The youngest case reported was that of labor in a girl eight years old; another case was of a twin pregnancy at thirteen years of age, and a third was that of one who was a grandmother when she was twenty-five years and nine months old. Following this are considered the physiology and pathology of pregnancy, abortion, extrauterine pregnancy, eclampsia and the obstetrical hemorrhages. In the section devoted to labor the dangers of chloroform anesthesia are noted, especially the dangers of delayed chloroform poisoning. Presentation and their treatment, complications, and operative obstetrics are also considered. The advantages of early rising in the puerperium, defective nipples, puerperal sepsis, psychoses during pregnancy and the puerperium are discussed in part three. About a half dozen pages are devoted to the pathology of the infant. The book is extremely interesting and instructive. It gives one an insight into the various methods of procedure followed by the leading obstetricians throughout the world.

Volume VI is the second volume of the Practical Medicine Series, which has been devoted to general medicine. In it are considered infectious diseases, diseases of the gastrointestinal tract, and diseases of the liver, pancreas and peritoneum. Under the heading of miscellaneous are discussed tobacco toxemia, tetany, and the condition called "abdominal disequilibrium" by Fraikin and Grenier de Cardenal. The book reports many interesting cases and discusses improvements in diagnosis and treatment.

Children's Diet in Home and School. With Classified Recipes and Menus. A Reference Book for Parents, Nurses, Teachers, Women's Clubs, and Physicians. By Louise E. Hogan (Mrs. John L. Hogan), editor of "The Children's Library" and author of "How to Feed Children," "A Study of a Child," "Gov. Bulletin No. 56 on The Introduction of Domestic Science in the Schools of New York City," "Stories for Children," "The Education and Amusement of Children," Etc. Revised Edition. New York: Doubleday, Page & Co., 1910.

The little volume contains a good deal of information pertaining to the diet of children. A great part of this is taken from various works on dietetics. For infant feeding there is recommended a certain proprietary infant food, so that this part of the book reads like the familiar advertising circulars. There is no unity in the preparation of this book—it is more of a scrap-book of dietetic methods. There are some admirable features, such as the descriptions of school dietaries and lunch rooms, and the various recipes. A reference book that may answer the needs of nurses, physicians and women's clubs, if the writing of such a book were possible, is at any rate not found in this manual.

La Tension Artérielle en Clinique. Sa Mesure, sa Valeur Séméiologique. Par Dr. Louis Gallavardin, Médecin des Hôpitaux de Lyon. Paris: G. Steinheil, 1910.

This is a practical and at the same time scientific manual on the clinical value of blood pressure determinations. The author emphasizes the fact that the study of the arterial pressure is really the study of the functional capacity of the heart, as well as of the condition of the arterial system, and of the different viscera, particularly of the kidney. The first part of the book deals with the measurement of arterial tension by means of the technique of sphygmomanometry, giving the various methods based upon the examination of the circulation under the influence of compression; it also details the procedures utilizing the oscillations of the arterial wall at the point of compression; in other words the oscillatory method and its equivalents. The second part of the book describes the general symptomatic value of the determination of arterial pressure.

Thérapeutique Usuelle du Praticien. Par Albert Robin, Professeur de Clinique Thérapeutique à la Faculté de Médecine de Paris; Membre de l'Académie de Médecine. Paris: Vigot Frères, 1910.

This work is made up of lessons given by the author in his course on therapeutics at the Hôpital Beaujon, Paris. It does not pretend to cover the entire domain of medicine, but takes up the most common disorders encountered in daily practice, grouping together those that are closely related. This intensive consideration of comparatively few subjects is designed as a form of mental gymnastics, to train the student or practitioner to utilize what he already knows.

The Practice of Surgery. By James Gregory Mumford, M.D., Visiting Surgeon to the Massachusetts General Hospital, Instructor in Surgery in the Harvard Medical School; Fellow of the American Surgical Association. With 682 Illustrations. Philadelphia and London: W. B. Saunders Company, 1910.

This work does not pretend to cover the entire domain of surgery. As a clinical surgery it does not take up the principles of this subject except incidentally. The object of the author has been to present an account of the practice of surgery, as seen at the bedside, in the accident ward and in the operating room. The surgical diseases are taken up in their order of importance and frequency. This is an unconventional method and one whose didactic value cannot be questioned. Thus, the first chapter deals with appendicitis. The general practitioner who desires to review the modern aspect of surgery as surgeons see it, and who wishes to approach this subject from a viewpoint entirely different from that of his student days, will profit by a perusal of this book, whose style bears the classic elegance of the author's former writings. The distinctive beauty of the illustrations is in keeping with the text. To the student this book presents in its 1,000 pages a comprehensive survey of surgery and at the same time preserves the proper perspective in dealing with its growing and ever varying phases.

Society Reports.

WESTERN SURGICAL ASSOCIATION.

Twentieth Annual Meeting, Held in Chicago, December 19 and 20, 1910.

THE PRESIDENT, DR. JOHN P. LORD OF OMAHA, IN THE CHAIR.

(*Concluded from page 276.*)

Primary Suture of Subparietal Rupture of the Kidney.—Dr. F. GREGORY CONNELL of Oshkosh, Wisconsin, after reporting an interesting case of simple subparietal rupture of the left kidney, in which he resorted to lumbar incision and suture of the kidney 42 hours after the accident, with recovery, drew the following conclusions: 1. Owing to the rapid, recent increase in the number of reported cases, there was reason to believe that subparietal rupture of the kidney was more frequent than the literature would lead one to believe. 2. Shock, injury to other organs, and external evidence of trauma were frequently absent. 3. History of an abdominal contusion, followed by rigidity and hematuria, was sufficient to lead to exposure of the organ. 4. Slight lesions and complete rupture of the kidney could not be differentiated by clinical signs or symptoms. 5. Proof of the absence of serious rupture was called for before instituting the so-called expectant treatment. 6. Nephrectomy should be reserved for very extensive disintegration of the organ. 7. Conservative treatment, preferably by suture, was indicated in the majority of cases.

Dr. WILLIAM J. FRICK of Kansas City, Mo., said heavy blows or falls striking on or about the lumbar region should always be regarded as serious. The appearance of hematuria following such injury should be sufficient evidence upon which to make a diagnosis of rupture of the kidney, although the absence of hematuria following such injuries was not always absolute proof that the kidney had not been injured. In one case of subparietal rupture of the kidney, a complicated case, hematuria was very slight, although the damage to the kidney was apparently beyond repair. The patient did not live very long. The wound about the kidney was simply packed. Injuries of the kidney were nearly always followed by hematuria, but this was not invariably the rule. In a case of gunshot wound of the kidney there was not a trace of blood in the urine to be found, macroscopically at least, although the perirenal space was filled with blood. When a diagnosis of rupture of the kidney was made the kidney should be exposed by a lumbar incision, especially if it be an uncomplicated rupture of the kidney, as it was the only means they had of determining the extent of damage done to the kidney. They could not depend upon the amount of hematuria or any other sign. Knowing the ability of kidney tissue to repair itself, they should attempt conservative surgery in these cases. Nephrectomy should not be done unless the injury to the kidney parenchyma was so extensive as to preclude the possibility of saving enough of it to be of functional value, and unless the injury to the renal vessels was so great as to seriously interfere with the nutrition of the organ.

Dr. GEORGE N. KREIDER of Springfield, Ill., stated that if he might combine a little remark in regard to Dr. Sala's paper with this one he would say that with the latest development of the *x*-ray picture they could definitely outline the kidney, differentiating the pelvis from the substance of the kidney by the Snook type of *x*-ray machines. Another valuable item he saw in one case, and which might be of advantage also in connection with the *x*-ray, and that was to give the patient methylene blue, which would undoubtedly cause staining of the tissues about the injured kidney, and this, with the radiogram, might prove of great assistance in the diagnosis of these cases.

Dr. B. B. DAVIS of Omaha thought a great many nephrectomies had been done in the past unnecessarily, and they were beginning to realize the wonderful reparative power the kidney possessed. He had had one case in which he cut off the lower end of the kidney, removing about one-third of the organ, and putting in a mattress suture below, with recovery of the patient. He believed that in many of these cases the suture was very much to be preferred to gauze drainage or gauze used to control hemorrhage.

Dr. F. A. DUNSMOOR of Minneapolis stated that there was one point which might be added to those that had been brought out in connection with this paper, and that was this: it was not the mere escape of blood which produced death in these cases, but it was the mixture of urine with the blood and its absorption into the tissues which caused death, particularly in these complicated cases, in which the abdominal cavity was contaminated.

Dr. ARNOLD SCHWYZER of St. Paul stated that as to the diagnosis blood in the urine might be very scant. In one case of injury to the kidney that came under his observation the first urine which was drawn with catheter in the hospital was not examined, and this was about two hours after the injury. The first urine they got should not only be examined by the eye, but microscopically.

Dr. A. W. ABBOTT of Minneapolis wished to speak of some experiments which were made by a Minneapolis physician (Dr. J. Frank Corbett) for the purpose of determining the ultimate results of injury to the kidney. In the first place, where the kidney had been injured and the capsule only sewed together, if there was much hemorrhage left in the kidney it was followed by inflammatory trouble usually, and then by a scar, and a large part of the kidney was rendered useless. The same results followed packing. The best results were obtained by the through and through suture which passed through the kidney directly and about the outer limits of the pyramid. This was followed by less scarring, etc.

Dr. DANIEL N. EISENDRATH of Chicago wanted to indorse the position taken by Dr. Davis in contradistinction to that taken by Dr. Connell and Dr. Frick, and his experience was based on a personal observation of fifteen cases of subparietal rupture of the kidney. The conclusion, from the study of these cases, had been forced more and more upon him that the more conservative they were in the treatment of subparietal rupture of the kidney the greater would be their percentage of recoveries, and he thought that was the tendency they saw in the foreign literature on this subject. He had seen some extremely severe cases where he thought he would do nephrectomy, but he had watched these patients bleed and bleed, and by simply leaving them alone they had recovered. Why did they recover? Granted that the kidney was extensively impaired, they knew these patients were not good subjects for operation; they were suffering from considerable shock, and the manipulation necessary to find and grasp the bleeding artery, which perhaps had already become partly or completely occluded by blood clot, and then started up hemorrhage in a fresh field, was attended with more harm than if they let these patients alone. They knew from experimental work on the kidney that if they tied off the renal vessels and left the kidney *in situ* that kidney underwent complete atrophy, and within a period of a few months the kidney would be a mass of cicatricial tissue. That condition undoubtedly took place in a certain proportion of cases where the kidney had been severely injured.

Dr. E. W. ANDREWS of Chicago stated that he had seen a man with a ruptured kidney on whom he had operated and declined to remove the kidney, because he thought he had successfully ligated the bleeding point, three days afterward get another severe violent hemorrhage and die

within a few minutes. They could not get away altogether from the old teaching that a ruptured kidney was apt to terminate fatally conservatively treated, that was, nothing being done in the way of interference. He did not think they should stand by and let these patients with ruptured kidney have one hemorrhage after another without doing something for them; but it did not necessarily follow that nephrectomy was the only operation of choice in these cases, for sometimes, as he had done in the case of injury to the spleen or liver, they could make a closure operation. In addition to ligating the bleeding points they could close the injured kidney with rows of mattress stitches, and if such an operation was done under aseptic conditions it might give a percentage of successful results which would compare favorably with nephrectomy as a life-saving measure.

Dr. Walter Courtney of Brainerd, Minn., wanted to say a word about differential diagnosis between contusion of the kidney and rupture. He had seen a good many cases of injury of the kidney. t the surgeon would wait a few days, as he might in most cases, provided hemorrhage was not alarming and secondary anemia had not taken place, a large number of these cases would gradually clear up, and it would be found that the kidney had only been contused.

Dr. James E. Moore of Minneapolis stated that it was only in exceptional cases that a nephrectomy was justified for rupture of the kidney. A patient was brought into the University Hospital recently, thirteen days after he had been thrown in a runaway accident, and presumably had sustained a ruptured kidney. He was brought to them in a moribund condition, with his bladder full of clotted blood. He died. At the post-mortem examination they found that he had sustained a rupture of one of the terminal branches of the renal artery just before it entered the kidney, and the presence of blood in the urine was accounted for by the fact that through pressure the blood was transmitted along and had broken through into the pelvis of the kidney at a point below and finding its way down the ureter into the bladder.

Dr. Donald Macrae of Council Bluffs, Iowa, said it seemed to him it was well to take a middle ground in dealing with injuries of the kidney. If they made a positive diagnosis of post-peritoneal rupture of the kidney or of contusion, the case was not fraught with as much danger as other forms of injury to this organ. But if they found a patient was going to the bad he thought they should resort to incision, with drainage or whatever was necessary to be done at the time. It was better, however, not to fuss with the kidney if they could help it.

Intussusception with Special Reference to Adults.—Dr. Ellsworth Eliot of New York City said that intussusception in adults was of more importance than previous study would indicate. The causes in children were largely confined to acute intestinal disturbances, while in adults they were more varied. The rarer causes were foreign bodies and parasites, less so ulceration from diarrheal diseases, tuberculosis, fecal masses, etc. A more common cause was trauma, especially severe muscular effort. Meckel's diverticulum was more common in children. The most frequent cause was a tumor, especially the benign polyp, with constricted base. The clinical course in children was fairly characteristic, while that in adults varied from one most acute to the very chronic. In his paper he tabulated three hundred cases arranged with reference to etiology and the clinical picture. Of the individual symptoms there was a great variety. Constipation was the rule, but normal stool or diarrhea might occur. Blood or mucus in the stools was less frequent and usually signified a tumor. A tumor varying in size and shape, especially during the attacks of pain and changing its position along the course of the colon, was characteristic. The tumor appeared first in the right lower quadrant, but should be looked for in the pelvis or in a position covered by the liver or spleen. Distention, general or focal, was variable. The course in the attack was usually very severe, especially in these cases with Meckel's diverticulum. In the protracted cases the natural processes might cause sloughing of the intussusceptum which was passed by rectum. Of these, forty-three cases were collected. Hope for such relief should not encourage conservative measures of treatment, for in usually less than 18 months secondary obstruction occurred. He suggested, therefore, that after the acute symptoms had disappeared lateral anastomosis be done, connecting the bowel above with that below the affected portion. Treatment should in most cases be radical. With conservative measures complete reduction was never certain; recurrence was likely, and the initial manipulation lowered the resistance to subsequent operation. Reduction in the first 24 hours was accomplished by combined expression and contraction in from 10 to 15 minutes, reduction by either alone being dangerous. Recurrence was avoided by anchorage of the cecum to the abdominal wall, by plication of the mesentery or by long longitudinal endoplication of the cecum along the anterior longitudinal muscular band. Gangrenous intussusceptum and intussuscipiens demanded resection followed by anastomosis or temporary enterostomy. A viable sheath might be split along longitudinally and through this the intussusceptum resected. Temporizing measures were enteroanastomosis and artificial anus. The procedure of choice was to gently reduce as far as possible and then resect. Complete reduction followed by resection was employed only where a tumor or the like was concerned. He reported two cases; one in a male, aged 40. Following a history of severe cramps three months previously there was an acute attack lasting 24 hours with pain, vomiting, abdominal tumor, one normal stool and blood in the rectum. Examination showed distended loops of the intestine. At operation there was an enteric invagination with a polyp the size of an English walnut near the apex. Recovery after resection. The second case was a female, aged 67, who had epigastric pain four months previous to operation; a clear interval until three weeks and then a recurrence sustained with a tumor in the region of the transverse colon. A high enema reduced the tumor, but obtained very little feces. There was no obstruction. Operation was delayed because of lack of symptoms and to increase her strength. Operation showed an ileocolic invagination with a polyp at the apex. Recovery took place after partial reduction, followed by resection.

President's Address.—Dr. John P. Lord of Omaha greatly deplored the giving of commissions and dividing fees, and said that realizing as he did that the practice of fee-division, secret division, joint fees, commissions, graft, and possibly money under false pretenses was increasing at an alarming rate among the younger element, and that in many cities and towns it was the usual thing, he undertook to arouse the members from their seeming lethargy. Teachers and hospital surgeons, as a rule, were established in their respective communities, and had not felt the force of this evil to so great a degree as to compel action. Those who followed would feel it keenly. Many young men were wrestling with this moral problem and would yield to the general trend of practice unless some aroused moral force within the profession or the effect of publicity checkmated this menace to professional honor, dignity, common honesty and decency. He agreed with those who favored publicity as the speediest and most effective remedy. Then, too, they needed some Roosevelts to keep up a rapid fire attack upon this dishonest practice, and they should maintain a professional and public sentiment against any countenance of graft. The practitioners who had for years adhered to an in-

elastic fee bill found themselves with their financial wings clipped and unable to rise above the level of customary fees. The specialist was something of a law unto himself and most often got what he asked. These practitioners, therefore, availed themselves of the specialist's faculty of fee getting and asking to add a sum for them, as the people would object to paying them a proper amount.

The medical schools had been remiss in their ethical instruction to students. The subject had been eschewed in some faculties for fear of engendering feeling, developing strife, and endangering the integrity of the organization. The same silence had prevailed in medical societies because it might cost something to speak. Students were now without the close contact that was enjoyed in the days of the preceptors, whereas they now needed more of the moral and ethical side than ever before.

There had already been more harm done than could be overcome for a generation. Delayed action meant more sacrifice. The organized profession should busy itself in reformation and take its stand in the medical colleges, hospitals and societies, and as individuals, and organizations educate the public and reform their own members. The most hopeful view might be taken of the result. Any practice which even smacked of graft, or of obtaining money under false pretenses could not endure before a righteous public opinion. Nor would it continue in a profession which had cherished ideals from Hippocrates and the whole line of medical saints, religiously followed by the vast majority during all the ages of the history of medicine.

Intestinal Obstruction Due to Kinks and Adhesions of the Terminal Ileum.—Dr. Charles H. Mayo of Rochester, Minn., stated the stomach suffered from many reflex conditions; only one patient in ten with gastric symptoms showed actual lesions. Many bowel conditions, as obstruction, appendical concretions, simulated symptoms of ulcer. The development of the mid-intestine included from below the common duct to and including the part of the transverse colon. Ten inches of the ileum was pelvic, was originally fixed to the cecum, and became detached at first except for a lateral opening. When this failed to take place obstruction was more liable to occur. In extensive appendical operations, in cases with obscure symptoms, Mr. Lane had noted an intestinal kink near the ileocecal valve. He believed this to cause obstruction, often non-inflammatory, and probably resulting from traction of the loaded cecum to the pelvis. The symptoms often simulated those of appendicitis, ulcer and various forms of constipation. They had seen many cases of this nature, both of inflammatory and non-inflammatory origin, and producing reflex symptoms. Therefore, with the present increased facilities for intestinal exploration, the four terminal inches of the ileum should be examined when possible in obscure cases of digestive disturbance.

The Selection of Operation for Inguinal Hernia.—Dr. Archibald Maclaren and Dr. Harry P. Ritchie of St. Paul gave the abridged records of 105 anesthesias showing 123 operations in 97 individuals. The greater number had come during the period of active life and because of the occurrence of new symptoms or the failure of the truss to retain the hernia. No extraordinary measures, such as filigrees or flaps of the recti, were found necessary to obtain satisfactory repair. During the first decade the operation without the most positive indications was often questioned. It was no old experience to have the truss obliterate the sac, and when recurrence did come it would usually result in a less complicated form of hernia. During the second decade and beyond their advice was positive, as the presence of the hernia was then permanent. Two deaths had occurred, both from strangulated hernia. The total number of strangulations was eight; three of these were in the third decade and the remaining five in the sixth and seventh. Of the complications of convalescence seven cases had notes of wound infection, only one of which was severe. All cases suffering an inflammation to any degree were instructed particularly as to the possibility of recurrence. The appendix had been removed 26 times at the same time as the herniotomy, usually through a buttonhole in the internal oblique muscle. In one case a herniotomy and a cholecystectomy were done at the same time. Eighteen cases were operated upon for a double hernia. They had as easy a convalescence, and there was no reason why the side opposite should not be investigated and a hernia in its inception cured. There was a record of six relapses, two of which were in women. The problem of the disposition of the round ligaments was unimportant in relation to the cure of the hernia. Here the operation should be called a herniotomy and was not to be placed to the credit or discredit of any of the well-known methods. Of the 98 operations on men there was one Halstead with cure, 55 Bassinis with one return, and 42 Fergusons with three returns. Previous to 1905 there were two cases in which, from their description, the cord was not displaced, but in all others (34 in number) a Bassini was done. One relapse had occurred and had been reoperated upon, but the remembrance of the technique of the first operation was such that the failure was ascribed to this rather than to the principle. Beginning in February, 1905, they were influenced in the use of the Ferguson operation. This was done as a routine operation 42 times. The three returns had all been repaired, and the conditions found were identical in each case. There was no sign of the old hernia, but a new one had formed at the most dependent part of the canal. The sac came directly through to the inner side of the cord. When the sac was removed it was easily demonstrated that if the tissues were replaced as before this defect would be uncorrected, and there seemed to be no reason why the sac would not immediately recur. The only possible procedure was the use of the conjoined tendon and the displacement of the cord, thus performing a Bassini. The per cent. of their success as to the displacement or non-displacement was in favor of the former. In view of the formation of an entirely new kind of hernia which came without displacement of the cord, and which they were powerless to prevent, it had swung the pendulum back in favor of the Bassini, and our present feeling was that if there was a recurrence we would call it an operative fault and do it over again.

Typhoidal Cholecystitis.—Dr. John E. Summers of Omaha, Neb., said that much discussion had taken place as to the mode of invasion of the gall-bladder by the typhoid bacilli. According to Chiari the route of infection was not by ascension from the intestinal tract, but his theory of gall-bladder infection by the typhoid bacillus was, first, the intestine, then the blood, and then the gall-bladder. Dr. Summers reported several cases, one of which was a pure case of typhoidal cholecystitis, the gall-bladder involvement giving symptoms at the beginning of the first relapse. The absence of any obtainable history of gallstones prior to the illness could fairly fix the initiation of the formation of the stone found in the common duct as taking place probably during the first part of the attack. The time from the beginning of the attack to the time of removal of the stone was from April 1 to August 22—sufficient time for its formation. In so far as he was informed, this was the first case of typhoidal cholecystitis with probable formation of the stone during the attack in which the stone was removed from the common duct. Cultures from the center of the stone were sterile—a finding which did not negative the origin of the stone as due to typhoidal cholecystitis. Cholecystostomy upon typhoid carriers, he thought, should be done whenever there was evidence of any infection in the gall-bladder or ducts. In

cases where no signs of inflammation could be found, it might be considered that possibly the nesting-place for the bacilli was in the diverticulum and operation not indicated. There was favorable evidence for the carrying out of cholecystostomy in these dangerous persons.

Plication of the Anterior Broad Ligament for Retrodisplacements.—Dr. A. W. Abbott of Minneapolis said the round ligament was not a natural support of the uterus, while the broad ligament was. Suture of the broad ligament just below the round ligament made an efficient support and conformed to the natural anatomical requirements. The operation was rapidly done. The failures were less than by other methods, and there was less pain after the operation.

Abdominal Exclusion of the Fundus in Complete Procidentia.—Dr. Joseph Rilus Eastman of Indianapolis stated that the question as to whether the uterus in its normal state was suspended by its ligaments and thus secured in position or was supported or upheld by the muscles and fasciæ of the pelvic floor; the ligaments, serving only as guides, became in the presence of complete procidentia a question of lessened importance, for in these extreme cases hysterectomy or the abdominal operation with fixation was absolutely necessary, in addition to a thorough repair of the vaginal supports, with amputation of the elongated portio vaginalis and curettage. The fixation here referred to was not a classical one by which the fundus was sutured to the abdominal aponeurosis, but one in which the uterine fundus was drawn quite through the abdominal wound, the entire fundus being excluded and secured with a large transfixing pin. The pin was allowed to remain in place for two and one-half weeks. It was not a rare experience to find, a few months after a simple fixation, the abdominal wall sunken in at the site of fixation and the prolapsus returning. In excluding the fundus in cases of complete procidentia, the aim had been to fix the uterus higher than could be done by an ordinary fixation, to provide for firm attachment of the peritoneum, muscles and aponeurosis at a low level upon the anterior, posterior, and lateral aspects of the uterine body. All of the layers of the abdominal coverings were drawn snugly around the uterine body and sutured to that organ anteriorly, posteriorly, and laterally. The transfixing pin in the three cases reported was passed deeply enough to exclude the entire fundus. Two patients thus operated, though they were past 50 years of age, had not passed the menopause, and in one of these the uterine appendages were removed and in the other the tubes were divided and the peritoneal screen suggested by Ries interposed. In all three cases the abdominal operation was preceded by curettage, amputation of the cervix, anterior and posterior colporrhaphy, and perineorrhaphy. In each case the fundus had been covered over with skin growing centrally from the periphery within two or three weeks. Owing to the firmness of the attachment and the elevation given by the transfixing pin, the possibility of sagging or detachment was minimized. The method offered the greatest possible uterine surface for fixation in the abdominal coverings. It made possible reduction of deformities caused by extreme relaxation as a simple intraabdominal fixation could not do because the uterus was drawn higher and the firmer fixation prevented a yielding ligamentous fixation or a complete sundering of the attached structures, an accident which was perhaps less rare than was imagined.

Lesions of the Hip-Joint and Their Management.—Dr. John B. Murphy of Chicago spoke of the elements in connection with lesions of the hip-joint and of an important principle governing the final results obtained in pathological conditions and in fractures. In his recent work in connection with fractures in attaching the upper end of the femur frequently he found a definite condition occurring, namely, absorption of the neck. No such absorption took place in fractures in any other part of the body. It never occurred when there was a fracture in the upper end of the humerus. This absorption was due, he believed, to the primary condition of the circulation in the neck of the femur. When there was a fracture, a lesion or disease, the repair of that lesion depended more upon the condition of the circulation in the neighborhood than on any other one thing, taking into account always the regenerative potency of the individual structure. In fractures that occurred close to the head of the femur there was practically no absorption at all; no fatty degeneration, no breaking down, no liquefaction of bone. When a fracture occurrred close to the base of the neck and there was attachment to the trochanter, it did not tear off the blood vessels in the capsule inside. That capsule went down and out and back in again, and the blood vessels went in a proximal and distal direction, but the bone for a certain distance in a great majority of cases was absorbed. If there was a fracture of the neck of the femur which did not tear off the blood vessels, then the portion between the trochanter and the head remained, and it was capable not only of revascularization, but of ossification, regeneration, and of sustaining the neck. In the management of fractures of the femur, it had been the custom to dress them with a straight external splint. What did this do? It tended to shortening by shortening of the adductors, and shortening of the gluteal group of muscles attached to the trochanter, and not only that, the tendency of the adductors was to draw the limb inward, and there was shortening in that position. What the surgeon wished to do was to reduce to a minimum contraction during the process of absortion of this portion of the head of the femur, so that when absorption had taken place and the tissues were ready for regeneration, it was essential to have the parts in apposition. They could be best maintained in apposition by relaxing the group of muscles which did so much to cause shortening by putting on extension. The ambulatory management of tuberculosis of the head of the femur was wrong in his opinion. An ambulatory apparatus was applied to prevent motion, and so far as it inhibited motion in a joint it was valuable. But what should it be applied for? To prevent pressure on the inflamed part. When the products of infection were held under tension there was rapid destruction of tissue. This tension should be relieved. The first main principle should be to separate these articular surfaces by an extension apparatus, and then build up the patient to stimulate the process of repair.

Dr. B. B. Davis of Omaha read a peper in which he spoke of Meckel's diverticulum as a cause of ileus.

Officers.—*President*, Dr. Amos W. Abbott, Minneapolis, Minn.; *First Vice-President*, Dr. A. E. Halstead, Chicago, Ill.; *Second Vice-President*, Dr. William Frick, Kansas City, Mo.; *Secretary-Treasurer*, Dr. Arthur T. Mann, Minneapolis, Minn.

Kansas City, Mo., was selected as the place for holding the next annual meeting, and time, December 18 and 19, 1911.

THE MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, Held December 19, 1910.

The President, Dr. Reynold Webb Wilcox, in the Chair.

Nomination of Officers.—Dr. Thomas Darlington was nominated for Chairman for the Borough of Manhattan, and Dr. Ross McPherson for Member of the Council.

Morbific Processes Controlled by the Hypodermatic Use of Aseptic Chemical Solutions.—Dr. J. Blake White read this paper in the field of therapeutics. He said there were no facts better established to-day than the

prompt and energetic absorption of vegetable and mineral substances, administered subcutaneously, and their favorable action on diseased conditions. We were living in times when quick results were demanded and expected. There was far less need, it appeared to him, of new therapeutic agents than of a much better knowledge of those we already possess. He had an abiding faith in our ability to secure good results with the remedies now at our command if we devoted proper attention to their action and the most efficient modes of administration. The time was fast approaching, if it had not already arrived, when an assurance could be felt that by the judicious selection and skillful use of remedies employed hypodermatically diseased action can in many instances be summarily checked. There never was a time, however, when greater caution was required to avoid being misled by popular clamor in favor of some pretentious antitoxin. Tomasoli claimed remarkable results from the hypodermatic injection of a solution of common salt and sodium bicarbonate, and as similar reports had been made by other reputable authorities, the question arose, how much, if any, of the alleged virtues ascribed to some animal serums may not be justly attributed to the active antiseptic agency of their intermixed saline ingredients, if not to the presence of the antiseptics used for their preservation? Though the effects of hypodermatic medication were most marked in affections involving the nervous system, there were many others in which the superiority of this method of administration had been shown. An important application of its usefulness was brought to notice by Dr. Moore, of the Bombay medical service, in the treatment of malarial fevers, in which quinine was successfully given in one-fifth the dose that would have been required by the mouth, and with much more positive results. It must be conceded that the hypodermatic method is far superior to the stomachic, rectal or endermic modes of administration, particularly in emergent cases, where the indications are for anodynes, or antispasmodics, or when it is desired to arrest the absorption of some septic matter. There was not much certainty about the stomachic dose, so liable to be rejected, and, if retained, so apt to be only partially absorbed, while if it were wholly absorbed it was in so slow a manner as to do no real good. The particular mode of action of chemical compounds introduced hypodermatically was still obscure, but some explanation might be ventured in the view advanced that certain simple antidotal influences are brought about upon somatic poisons which threaten to derange the blood and tissues, by destroying the toxins in which the pathogenic germs present flourish. Recent researches also seemed to demonstrate that they often act as reinforcing allies to the phagocytes. Such reinforcing effects had been observed a number of times from the hypodermatic injection of a combination of gold and sodium chloride with manganese iodide and strychnine arsenite in tuberculosis and some forms of anemia due to other causes, after other remedies of repute in such conditions had signally failed to produce any benefit when administered per os. In tuberculosis the speaker had continued to practise this method of treatment with gratifying results. Having given an historical resumé of the hypodermatic method, he stated that an admirable classification of remedies to meet particular conditions would be found in Bartholow's Manual of Hypodermatic Medication. Even now, however, the public was not yet sufficiently educated to appreciate the full value of this manner of administering drugs. Having used the method very extensively for over fifteen years, and having met with a large number of convincing proofs of its utility, it was not to be wondered at, he said, that he unhesitatingly advocated its more general adoption, and that he preferred to use pure chemical substances rather than the less understood animal serums so much flaunted at the present time. It was without fear of proof to the contrary that he was ready to record the assertion that no benefit can be obtained from animal serums which cannot be realized from well selected and prepared chemical solutions administered in like manner for the same purposes. Many eminent surgeons reported that the antistreptococcic serum had often disappointed them when used to combat septic conditions, whereas the solution of carbolated zinc sulpho-borate, with kolein, which he had employed on several occasions, would check the progress of pathogenic germ absorption with a degree of certainty that was surprising. Instances of this favorable action were cited, one of them being in his own person when he was threatened with septicemia from a wound of the finger acquired while operating on a septic patient. In selecting remedies for hypodermatic use it was of first importance to secure those which were readily soluble and were least likely to cause irritation. The relative therapeutic dose should be carefully determined, and the effects always closely watched, so as to guard against the manifestation of idiosyncrasies. Freshly prepared solutions should always be used, and for the menstruum sterile water was preferable. The syringe should be of such construction that there would be no possibility of conveying any contaminating material into the system through its agency. Usually not more than 10 or 15 minims of a solution carrying the necessary medication was advised for an injection. The preferable localities for making injections were the lateral lumbar regions and about the abdominal walls, where there was abundant cellular tissue under loose integumentary structure. Having described the most approved *modus operandi* in making hypodermatic injections, Dr. White said he had administered as many as 150 or more injections to the same subject. Though selecting different sites for the operation, he had made some of the injections in close proximity to each other without observing the slightest indication of any local irritation. In several thousand such operations, extending over a period of many years, he had never noticed the appearance of an abscess.

Dr. Boleslaw Lapowski said that the reader of the paper had strongly advocated the subcutaneous use of soluble solutions. In cases where we wished to relieve an acute pain or other distressing symptom, the injection method was the quickest and most desirable. But to give preference to the hypodermatic method, even with soluble solutions, in chronic diseases we must first be more familiar than we were now, in our present state of knowledge, with the absorption, action, and elimination of the remedies used. The method of Prof. Ehrlich, employed in the discovery of "606," had changed our conception of the mode of action of arsenical preparations, and it was greatly desirable to investigate by the same method the action of other medicinal preparations, like mercury and quinine, before a more extensive hypodermatic use of such remedies could safely be advocated and urged, in preference to the methods of administration. Our present knowledge of the various changes which the remedies undergo when introduced into the living system was very unsatisfactory, and clinical observations, rather than theoretico-physiological conceptions should guide us in their administration. In the use of the hypodermatic injection the clinical maxim, *non nocere*, must be our prime guide. With such experience and skill as the reader of the paper had, it was easy to avoid secondary infections, abscesses, and even nodular formations, which might often follow repeated injections. When quick absorption—the main advantage of hypodermatic injection—was not desirable, the combination of other methods with the hypodermatic was more indicated. Here, he said, he would like to draw attention to the fact that in cases of the protracted use of arsenic by the mouth we must be careful in administering the same arsenic; even in a dose four times as small as the

dose taken by the mouth. This was noted in several cases of lichen planus; one hypodermatic injection of arsenic, after a long use by the mouth, produced symptoms of arsenical intoxication, even when the dose was one-fourth of the dose by the mouth. In other conditions, like syphilis, where the prolonged internal use of mercury produced toxic effects, often mistaken for manifestations of the syphilis itself, hypodermatic injection would help us to introduce mercury without the undesirable toxic effects. With our present knowledge of the chemical changes of medicines during absorption, the supposition that the same remedy might undergo different changes when coming in contact with different tissues could not be disregarded, and to carry out the maximum *premium non nocere* the physician would take advantage of other methods of application, as by the skin and by the mouth.

Dr. Ransford E. Van Gieson said it had been his lot to see a great many hypodermatic injections and his unpleasant experience to have received a large number on his own person. He thought, therefore, that he was competent to form an intelligent opinion concerning this method of medication. For one thing, it assured quick results, and when one was suffering from the intense pain resulting from the passage of renal calculi or gallstones, as he had experienced personally, quick results were certainly very highly appreciated. Again, the method was of great practical service when from the presence of nausea the stomach was unable to retain remedies given by the mouth. As to a large number of injections being borne without inconvenience, in one instance he had given an average of two injections daily for fourteen months continuously, and there had never resulted the slightest trouble. In cases of this kind it was his practice to make the injections successively in different parts of the body. In general, it might be stated that whenever quick results were desired, the hypodermatic method should be employed.

Dr. J. Herman Branth said that if abscess resulted from a hypodermatic injection we could safely blame the operator for introducing some form of microbial poison. If the syringe were clean, and perfect asepsis were observed in making the injection, there was no chance for such a thing to occur. He could speak with some authority on this point, for he had received as many as two hundred injections in his own person.

Dr. White, in closing, said he appreciated fully the wisdom of Dr. Lapowski's caution in the use of remedies hypodermatically. Personally, he never gave a full dose the first time, but gradually increased the dose as he found out the tolerance of the patient.

The Question of Reflex Disturbances.—The special order of the evening was a symposium on this subject.

Reflexes in Surgical Diagnosis.—Dr. Robert T. Morris said that in the matter of specialism we had turned the pivotal point and had now reached the region of diminishing returns. We must get back to the good general diagnostician. There was reason for this when, as had been his experience and that of many other surgeons, patients were sent on here for operation in whose cases there was no occasion whatever for operative interference. For instance, an individual might be suffering from many of the symptoms of gastric ulcer, when the condition was in reality due entirely to imbalance of the ocular muscles; so that if he had the good fortune to be referred to a competent ophthalmologist, the whole trouble would be obviated by the employment of appropriate glasses. On the other hand, a child might have a persistent cough which was apparently of reflex origin and calling for medicinal treatment, when, in reality, the case was a surgical one, the cause of the cough being the presence of a bean in the ear. As to a case presenting symptoms of ulcer of the stomach, such symptoms might be due to one of three different classes of conditions: First, the patient might really have a gastric ulcer; second, the apparent ulcer might be due, by way of reflection, to eyestrain, loose kidney, gallstones, or some other similar source of irritation; third, the symptoms might be simply one of the manifestations of major hysteria. The same thing was illustrated in the case of flexion of the uterus. This might be due to actual anatomical defect (embryonic), though such instances were very rare; or it might be due to reflex peripheral irritation acting from a distance. A retroflexion of the uterus might, in fact, be the same thing as a sneeze. Again, it might be only one of the manifestations of a general neurotic habit. The speaker then narrated a case of facial neuralgia which was of reflex origin. In addition to other treatment, the patient, a lady, had been given alcohol injections by an eminent surgeon, but without experiencing any relief, and the pain was so agonizing that she was actually on the point of committing suicide. It proved, however, that the precipitating cause of the neuralgia was an ovarian cyst, and when this was removed the neuralgia disappeared. In this instance the precipitating factor in the causation of the neuralgia had been overlooked by several diagnosticians whom the patient had consulted.

Reflexes Dependent Upon Eyestrain.—Dr. E. M. Alger read this paper. We seldom stopped, he said, to think how complicated sight is or how large a portion of the brain is devoted to its perfection. So necessary and so difficult was the function of vision that four of the twelve great cranial nerves were devoted exclusively to it, while clearness of vision and coordination of the two eyes were secured by the joint action of fourteen separate muscles. When we stopped to think that most of us use our eyes almost constantly during our waking period, and that many tasks involve a continuous strain for hours at a time, we began to understand why vision necessitated expenditure of nerve and muscle energy beyond any other function. And when we further considered the very close relationship anatomically between the visual and other centers, it need not seem strange that what we rather loosely term eyestrain may exercise a profound and varied influence on those other functions. A patient was said to be suffering from eyestrain when his eyes were compelled to do work which was beyond their physiological capacity. Unfortunately, we had no exact standards for measuring this capacity—only a standard of average. We were especially badly off when we came to measure the important element of endurance. Just as the strongest man was seldom the most enduring, so the optically perfect eye might be absolutely incapable of enduring continuous hard work. It was, therefore, perfectly possible to strain even normal healthy eyes by over-use, though the chief strain came from the efforts of the abnormal eye to compensate for optical defects by increased muscular exertion. In each case we had to deal with an individual problem, and the determination of the exact point where the physiological passed into the pathological depended not only on a proper estimate of any optical defects present, but also on a careful consideration of the patient himself, his age, his health, his temperament, and the conditions under which his eyes were generally used. There were at least three distinct types of fatigue symptom, the muscular, the nervous, and the psychic. In speaking of the last-named Dr. Alger said that the patient with an astigmatism, for instance, saw all objects more or less distorted, and was under the constant necessity of performing a series of mental adjustments as to the size and shape of objects. Everyone now admitted that this was an important factor in the problem of the backward school child, but it was equally applicable to many an adult who was stupid and apathetic, irritable, or easily exhausted. Unless he recuperated nerve and muscle energy very rapidly, he was on the verge of nervous exhaustion all the time. The

relationship between eyestrain and some of the functional nervous conditions had never been properly studied, and would well repay investigation. In demonstration of this theory of eyestrain we could not expect the absolute proof that we required in an organic disease of germ origin. All the evidence was clinical, and as such should be very closely scrutinized. A whole series of cases in which relief of definite symptoms, such as headache, followed correction of eyestrain would be generally accepted as showing a relationship between the two. Even a single case in which definite symptoms were relieved by glasses, and recurred when they were left off, would be worthy of note if we could more definitely exclude the influence of suggestion. This possibility should never be forgotten, especially in the large class of neurasthenics and hysterics. There were many symptoms which resulted sometimes from eyestrain and sometimes from other sources of reflex irritation, and we could make a diagnosis only by a process of exclusion. It was generally admitted that eyestrain is the commonest cause of chronic headache, yet there were innumerable other possible causes. Examination of the eyes should be one of the first procedures, because the eye was such a common cause and because it took such a short time to exclude it. In regard to migraine the speaker said that every one of the individual symptoms of migraine were seen over and over again in eyestrain cases, and so far as his own experience went (including many cases of typical migraine), relief was the rule, and not the exception. He would not say they were cured, for presumably the hereditary instability was still there. While many ophthalmologists disbelieved entirely in the association of migraine and eyestrain, and there were of course many cases in which other factors predominated; in his own experience complete failures had been surprisingly few. We applied the indefinite term neurasthenia to multitudes of people whose chief symptoms were muscular and nervous irritability and fatigue manifested in many ways, and in this class he believed functional insufficiency played a far more important part than was generally supposed. In many of them eyestrain served simply as the last straw, but in many other it might be one of the basal conditions. There was no question, however, that an intelligent eye treatment would relieve many of the neurasthenic's most distressing symptoms, though he was also aware that some of this benefit was the result of suggestion. Many of the symptoms, in both women and men, so common at the time of the onset of presbyopia he thought we should recognize at once as possibly due to eyestrain. Had time permitted, he said in conclusion, he could have given clinical reasons for believing that the eyes may be the cause, in some cases at least, of functional anomalies of the stomach and intestines, such as nauseau and vomiting, of occasional cases of neuralgia and reflex abdominal pain ,and of some cases of wry-neck and lateral curvature of the spine. It would have been interesting also to say something of differential diagnosis and methods of treatment. He could only suggest that success depends on at least three factors: the skill of the physician in making his provisional diagnosis, the skill of the oculist in correcting errors, and the intelligence and tractability of the patient. In all three there was room for infinite advancement.

Reflexes Dependent Upon Nose and Throat Conditions.—Dr. M. Sohier Bryant said that reflexes and reflex neuroses emanating from the upper air tract were of greater variety and importance than those from any other region, and that this was explained by the fact that the nerve supply of the tract is largely sympathetic in character. Especially was this true of the nose, the sympathetic nerve supply of the nose being more abundant than that of any other superficial organ. Typical examples of simple reflex neuroses from the upper air tract were hay fever, rose cold, paroxysmal cough, paroxysmal sneeze In the group of complex reflex neuroses there were asthma, asthenopia, headaches, and aprosexia, as well as such other neuroses as were more difficult of demonstration, as cardiac and uterine pains. The simple reflex neuroses were caused by repeated or prolonged stimulation carried to the point of nervous exhaustion, while the complex neuroses depended upon structural and peripheral changes which caused abnormal nerve stimulation. In the first group the diagnosis could be made by experimentally inducing an attack. This was done by carefully stimulating with a cotton application every suspected hypersensitive part, until the active one was discovered and the reflex phenomenon produced. If the diagnosis could not be determined in this positive way, cocainization of hyperesthetic areas during a reflex paroxysm would stop the attack and establish the diagnosis. In the complex cases, as a rule, an attack could not be produced experimentally. If cocainization of hyperesthetic areas during a paroxysm did not indicate the point of departure of the attack, the diagnosis could be determined only through the treatment of local abnormalities. The treatment of reflex neuroses consisted in the elimination of the peripheral exciting cause, the hyperesthetic area, because the nerve path was less amenable to treatment and the fundamental neurotic tendency was still more resistant, while it was always possible to remove the peripheral cause. Removal by resection was preferable to cauterization, because by the former method the good effects were permanent, which might not be the case with the latter. When removal of the peripheral factor had been effected the prognosis for permanent relief from further attacks was good. In very neurotic patients a similar or different reflex neurosis occasionally appeared from some other part, but this neurosis in turn would yield to appropriate treatment.

Reflex Disturbances Referable to the Ear.—Dr. John Randolf Page said that reflex psychoses, as well as reflex neuroses, were met with in connection with affections of the middle ear, but, fortunately the instances of suicidal mania and profound melancholia referred to by some authors were rare. It was true, however, that headache and mental depression were often due to even slight catarrhal affections of the middle ear and eustachian tube which interfered with the proper ventilation of the inside of the drum. In such cases inflation through the eustachian tube afforded prompt relief. Slight inflammations of the middle ear occasionally caused intense facial neuralgia, which might be followed by temporary facial paralysis, and instances of herpes oticus were also occasionally met with. Some idea of the number and character of the reflex disturbances caused by irritation of the internal ear might be obtained from the statement that every symptom of seasickness in its most aggravated form can be produced by irritation of a normal labyrinth. The peculiar rapid movement of the eyes, known as vestibular nystagmus, observed in connection with irritation of the labyrinth was due to a movement of endolymph in the semicircular canals, and knowledge of this relationship between the eyes and the endolymph had been put to practical use in the tests for labyrinthine disease now in general use.

What Is the Meaning of Reflex?—Dr. Edward D. Fisher said that all action was reflex—breathing, swallowing, in fact, every act, unless it had its initiative from the brain, in some voluntary purpose. Even this, however, was indirectly reflex, since it depended on original, primary reflex action. The child when born had had no previous cerebral impressions—those entering into the conscious ego—because this had not as yet existed. The cerebral cortex was a blank sheet, ready for and by heredity prepared to receive impressions. At first the child acted simply reflexly: *i.e.* a sensory or apparent irritation or impulse was received by a cell group or center, which responded through its motor or efferent nerves. The

same reflex action took place in the spinal cord without its recognition by the cerebral cortex, or, in other words, by consciousness. When we spoke of referred reflex conditions we were dealing with actual states. We should be careful, however, not to misinterpret them. A reflex action was fundamentally the same in all conditions. From the simplest form of protozoal life to the complex mammalia we were always dealing with the efferent or sensory nerve irritation, the receptive center, and the efferent or executive action fibers. In the mammalian, repeated sensory impressions became permanently registered in the perceptive centers, and became memories; so that many reflex acts became automatic, though this could not have occurred unless they had passed through the primary simple process which had been referred to. When we tried to understand and explain all the conditions involved in reflex action it would be found that much must remain indefinite. The sympathetic system had its part to play, and this modified our idea of the simple character of a reflex act, as seen in the spinal cord and brain. We understood very little, either anatomically or physiologically, of the sympathetic system; it still remained practically a *terra incognita*. This was the reason that the theories of Head, so far as regarded our acceptance of them as of practical diagnostic value, clinically had failed of conviction. It was difficult to acknowledge positively that pain or sensory anesthesia in a certain area of the body indicates disease in an underlying abdominal organ, if by it we were to decide definitely on an operation. Academically, we could easily discuss the question or take it up in the laboratory, but the active, practical worker had to decide on a life and death issue. A pain was not necessarily reflex, but, a referred condition. Dr. Morris and others who had participated in this symposium had spoken of cases as reflex in character, in which, in reality, there was in no sense reflex action. It should be remembered that reflex is not only an afferent but also an efferent phenomenon. The confusion which existed in regard to this subject was due to the misuse of the term reflex. In cases such as those cited Dr. Morris had very properly insisted that we were not to make our diagnosis on a simple referred pain, but ought to take in all the features presented, as brought out by a thorough general examination of the patient. Thus, we should not speak of the gastric crises in tabes as reflex In this disease the reflex action was lost. If we substituted the designation "referred" for the "reflex" so commonly spoken of, we would have a clearer conception of the actual conditions.

Reflex in Diseases of the Nervous System.—Dr. William M. Leszynsky said the reflex theory of nervous disease, which was of very ancient origin, was based upon mistaken notions about reflex action and had often been confounded with associated disturbances of sensation. Its practical application often implied carelessness or inaccurate observation. We had all occasionally noticed the subsidence of nervous symptoms following the removal of adenoids and enlarged tonsils, the correction of refraction and eye muscle defects, the removal of impacted cerum; the relief of phimosis by circumcision, the ablation of diseased ovaries and adnexa, etc. But it should always be borne in mind that a coexisting neurotic state was usually intensified and not produced by any of the derangements mentioned. While these or similar conditions might cause pain, spasm, convulsion, or other distressing nervous symptoms, they had never been known to develop a constitutional neurosis such as neurasthenia, hysteria, hypochondriasis, epilepsy, or insanity. The term "reflex neurosis" came into existence about thirty years ago, when practical medicine was subdivided into a number of specialties. It was to be deplored that the same old unjustifiable expression was still heard from time to time; thus illustrating the difficulty of overcoming traditional custom. To those who still adhered to the exploded doctrine of the ancient reflex theory it might be said that the perpetuation of such a misconception had repeatedly been conclusively demonstrated to be unscientific and irrational. That it was our duty to make every reasonable effort to discover the cause of apparently inexplicable nervous phenomena was axiomatic. A slight physical defect might be insignificant in one individual and inconsequential in another, but to interpret, as some had done, such deviation from a standard which was purely arbitrary as the reflex cause of disease of the nervous system was a *reductio ad absurdum*. Among notable medical fallacies, none had been more prominent and persistent than that of attributing seemingly obscure manifestations either to some reflex irritation originating in the female genitalia or to so-called imbalance of the ocular muscles. In the majority of instances the causal relationship could not be satisfactorily established except in the fanciful minds of those with preconceived notions, and absolutely authentic cases were extremely rare. As to published reports of cases of chorea, epilepsy, insanity, etc., having been cured by the surgical adjustment of ocular muscles, he had no desire to question the judgment or veracity of certain observers; but many of the cases thus reported would not successfully bear critical neurological analysis. To assert that patients have recovered from these neuroses after the correction of ocular defects, oöphorectomy, or cauterization of the nasal mucous membrane, urethra, etc., was begging the question, and did not necessarily imply that such affections were of reflex origin. In many cases the alleged rapid (but usually temporary) recovery had been due to suggestion, and the same result might often be accomplished by simpler and safer means. The disastrous effects of the reflex theory of nervous disease were quite familiar, and required no further demonstration; yet its misapplication was still more or less prevalent. The unfortunate tendency to ascribe many misunderstood symptoms to so-called reflex causes was due in a large measure to the neglect of the majority of physicians to avail themselves of a working knowledge of the fundamental principles of neurology.

Dr. J. H. Woodward said that although the subject of reflex had attracted so much attention of late, he felt that the discussion this evening would prove of great service. It must be conceded that the practical contention urged by Dr. Morris was well taken, namely, that the patient's entire system should be examined before any serious measures, in the way of operation, were undertaken. This was what this discussion amounted to if it meant anything at all. A given case might present a number of conditions referable to various organs, and in order to arrive at a correct diagnosis it would be necessary to collect all the data possible, and select such points as proved to have significance.

Dr. J. Joseph Kindred said that, as pointed out by Dr. Leszynsky, the symptoms of reflex in many diseases were often wholly misunderstood. Having referred particularly to the conditions met with in general paresis, he said we were certainly not yet entirely conversant with the symptoms of many of the deeper and more complex reflexes. He would, therefore, most earnestly commend the continuation of the research work in this field which had been carried on by C. K. Mills, Leszynsky and others.

Dr. Anthony Bassler said that he had been much interested in the work of Head. When he first read of this new theory he at once determined to investigate it practically as an aid to diagnosis, and for one year he conscientiously and diligently tested it in his clinical work. He was entirely disappointed in the results, however, as he found that there was absolutely nothing of practical value in the Head zones.

Dr. Edward Wallace Lee said that the more perfectly equipped to make an intelligent diagnosis the members of

the profession became, the less we would hear of these "reflex" or "referred" cases. The superficial manner in which many surgeons and physicians examined their patients was certainly most reprehensible.

Dr. Morris in summing up, said that Dr. Fisher's point about the misuse of the word "reflex," for which "referred" should be substituted, probably explained the reason why there was so much controvery over a subject which should be more stable. He had himself misused the term "reflex," and would now correct the error. He agreed with Dr. Woodward that the important thing for the diagnostician, was to get complete testimony from many specialists, and then edit the testimony. The position of the diagnostician as "editor" was his most important function.

Dr. Fisher said that, after all, what he meant was that in arriving at a diagnosis one should make a complete examination of the patient—all his organs.

Dr. Leszynsky said that in the case of facial neuralgia referred to by Dr. Morris it was not surprising that the patient did not get relief. Many cases of symptomatic facial neuralgia were due to toxic conditions arising in the intestinal tract, and it seemed probable to him that in this instance such a toxic condition was induced by the pressure of the ovarian tumor. As had been insisted, in all cases a thorough, and not merely superficial, examination of the patient should be made. He was glad to learn that the specialists were going forward, and not backward, for in this symposium he had expected to hear of all sorts of conditions being cured by operation. Head's theory had been studied by a number of well-qualified investigators, and it really seemed worthy of consideration. No one with experience believed that the simple presence of a zone of hyperalgesia would justify laparotomy. What was claimed was that there was an irritation of the visceral sympathetic nerves which was conveyed to certain spinal segments, and there reflected to a cutaneous sensory area corresponding with the neighborhood of the viscus involved. When found, it was valuable as a corroborative sign. The investigation of the Head zones was a waste of time, however, without the intelligent cooperation of the patient.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

West Virginia State Board of Health.

November, 1910.

ANATOMY AND EMBRYOLOGY.

1. Into what two general classes are muscles divided? Give a macroscopic and a microscopic description of each class.
2. Describe the external carotid artery as to origin, distribution, and branches.
3. At what stage of embryonic life does the development of the alimentary canal commence?
4. Give the general characteristics of a vertebra. Describe the atlas.
5. Give the classification of joints.
6. Describe the kidney and give its relations.
7. Describe the thorax; mention its contents.
8. Give the coverings of the brain.
9. Describe the humerus and give its muscular attachments.
10. Describe the esophagus.

PHYSIOLOGY AND HISTOLOGY.

1. Describe deglutition.
2. Describe the difference between tetanic contraction of a muscle and rigor mortis.
3. Arterial pressure: Describe it and how is it regulated and estimated?
4. Sight: Describe it. What is myopia; hypermetropia?
5. Tobacco: Describe some of the deleterious effects of tobacco when used in excess.
6. Name the organs of reproduction, male and female, and where is the ovum impregnated?
7. Pneumogastric nerve: Give origin and function.
8. Describe the clotting of blood; give theory of the genesis of fibrin.
9. Give general location of the motor areas of face, arm, and leg.
10. Give the histology of the human red-blood corpuscles, and wherein do they differ from those of reptiles?

MATERIA MEDICA AND THERAPEUTICS.

1. What is a drug? What are cerates, collodions, confections?
2. What are motor depressants? Name three.
3. What are mydriatics? Name three.
4. Name two preparations of arsenic. Give physiological action and name official antidote.
5. Mercury: Name three preparations, therapy, and dose.
6. Nux vomica: Name two preparations, physiological action, therapeutics, and dose of each.
7. Chloral: Source, dose, and indications for use.
8. Salol: Dose and indications for use.
9. Give procedure in writing a prescription; give example.
10. What are the actions and uses of emmenagogues; name two.

BACTERIOLOGY AND HYGIENE.

1. Define bacteria, pathogenic, saprophytic, leucocytes, and phagocytes.
2. What is an antiseptic? Give an example. What is a disinfectant? Give an example.
3. Define toxins, antitoxins, leucomains, and ptomains.
4. What is infection?
5. Discuss hereditary predisposition.
6. What patients would you not send to a high altitude?
7. What climate would you recommend to a rheumatic patient?
8. What is a fair average death rate?
9. What is the most sanitary method of disposing of a city's garbage? How dispose of sewage?
10. In what different ways may typhoid fever be communicated?

CHEMISTRY AND MEDICAL JURISPRUDENCE.

1. What are some of the various forms of carbon, physical properties, and economic uses?
2. Mention three standard solvents.
3. What are chemical incompatibles, and give examples.
4. How would you identify each one of the following gases: hydrogen sulphide, carbon dioxide, laughing gas, and ammonia.
5. Give one method of producing in the laboratory each of the following gases: oxygen, hydrogen, chlorine, and ammonia.
6. Name any four medicinal substances which are obtained from coal tar, and state their uses in medicine.
7. Describe Marsh's test for arsenic.
8. What are the signs of death by drowning?
9. How do gunshot wounds differ from other wounds?
10. Give the distinguishing marks between ante-mortem and post-mortem wounds.

PRACTICE OF MEDICINE AND PEDIATRICS.

1. Give causes of endocarditis.
2. What is sciatica? Give treatment.
3. Describe cause, give prognosis, and treatment of erysipelas.
4. How would you treat a case of cholera morbus?
5. What causes spotted fever? Give treatment.
6. How many different kinds of tapeworm? Give treatment for its expulsion.
7. Give the three different varieties of stomatitis and treatment of one.
8. Describe the peculiarities of the digestive organs in babies.
9. Ague: Peculiarities of and treatment in childhood.
10. Diarrhea: Symptoms, forms, and treatment of simple diarrhea.

OBSTETRICS AND GYNECOLOGY.

1. Name the external and internal female organs of generation and describe the uterus.
2. Differentiate ascites, ovarian cyst, and pregnancy before the fifth month.
3. What is placenta prævia? Name the different attachments of the placenta in the same. Give the method of management.
4. Give the symptoms and treatment of toxemia of pregnancy.

5. How would you treat a shoulder presentation with arm down?
6. Describe the various methods of preventing infection during childbirth.
7. Name some of the causes and some dangers incident to protracted labor.
8. Make a diagnosis of syphilis of the new-born; state something concerning the prognosis.
9. Give indications for hysterectomy. Which do you prefer, vaginal or abdominal? State upon what grounds you would base your preference.
10. Give cause and treatment of pruritus vulvæ.

SURGERY.

1. Describe the symptoms of pyothorax (empyema) and an operation for its relief.
2. Mention the dangers of anesthesia, and treat case of chloroform, ether, and cocaine poisoning.
3. Mention the most common causes of iritis. Give the symptoms and the surgical treatment of iritis.
4. Mention the indications for draining a wound and describe the methods of securing drainage.
5. Write briefly the history of a typical case of appendicitis with perforation, stating the order in which the symptoms most commonly develop.
6. Give the symptoms and the surgical treatment of hydrocele of the tunica vaginalis.
7. Give in detail the examination tests that should be applied to determine the causes of coma in a patient whose history is unobtainable.
8. Describe the early symptoms of tuberculous disease of the hip joint and mention conditions for which it may be mistaken.
9. Give indications for operative interference in cholelithiasis.
10. What are the varieties of dislocation of the shoulder joint? How would you reduce one variety?

SPECIAL MEDICINE.

1. Define and describe compensation and its failure.
2. Name the important points to be noted on inspection and palpation of chest.
3. How may the exanthemata affect the eye? Give treatment.
4. Diagnose and treat foreign bodies in the eye.
5. Diagnose and treat diphtheritic rhinitis.
6. Diagnose and treat peritonsillar abscess.
7. Differentiate catarrhal croup and membranous laryngitis.
8. Give pathology, diagnosis, and treatment of paralysis of the vocal cords.
9. Diagnose and treat paralysis of the musculospiral nerve.
10. Give the history, signs, and symptoms from which you would make a diagnosis of tabes dorsalis.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

WEST VIRGINIA STATE BOARD OF HEALTH.

November, 1910.

ANATOMY AND EMBRYOLOGY.

1. Muscles are divided into two great classes: Voluntary and Involuntary. *Voluntary* muscle is striated, has long narrow fibers with cross striations and many nuclei beneath the sarcolemma. *Involuntary* muscle is non-striated, has spindle-shaped fibers, one nucleus centrally located, and no sarcolemma. The great exception is cardiac muscle, which is involuntary and also striated.
2. See Cunningham's "Anatomy" (1909), page 803; or Gray's "Anatomy" (1908), page 602.
3. The development of the alimentary canal begins at a very early period of embryonic life, the enlargement which later becomes the stomach being noticeable as early as the fourth week.
4. The *general characteristics of a vertebra* are: Body or Centrum; and Neural arch. The latter consists of two pedicles, two laminæ, and seven processes (four articular, two transverse, and one spinous). For *atlas*, see Cunningham's "Anatomy" (1909), page 79; or Gray's "Anatomy" (1908), page 50.
5. CLASSIFICATION OF JOINTS: (1) *Diarthrodial*, or freely movable; as hip and knee. (2) *Amphiarthrodial*, or slightly movable; as symphysis pubis and joints between bodies of vertebræ. (3) *Synarthrodial*, or immovable; as ethmoid with vomer and parietal with frontal.
6. See Cunningham's "Anatomy" (1909), page 1130; or Gray's "Anatomy" (1908), page 1410.
7. See Cunningham's "Anatomy" (1909), pages 101 and 976; or Gray's "Anatomy" (1908), pages 156 and 558.
8. The *coverings of the brain* are the meninges (dura, arachnoid, and pia).
9. See Cunningham's "Anatomy" (1909), page 188; or Gray's "Anatomy" (1908), page 179.
10. See Cunningham's "Anatomy" (1909), page 1038; or Gray's "Anatomy" (1909), page 1235.

PHYSIOLOGY AND HISTOLOGY.

1. *Deglutition:* The masticated food is gathered up by the tongue and formed into a bolus between the tongue and the hard palate. The tongue is then pressed from before backward against the roof of the mouth, and the bolus slips back, through the fauces, and is ultimately grasped by the pharyngeal muscles and passed into the esophagus. The act of deglutition is divided into three stages: "The first stage is a voluntary act by which the food is carried back to the anterior pillars of the fauces. The second stage consists in the passage of the bolus from the anterior pillars of the fauces to the commencement of the esophagus; this is a reflex act, and is performed very rapidly, as the food has to pass over the opening of the larynx. As soon as the bolus arrives at the isthmus of the fauces the pharynx is prepared for its reception. The hyoid bone is drawn forward and upward, so that the larynx is protected by the base of the tongue, which projects over it; the epiglottis being closed at the same time and the vocal cords approximated so as to close the rima glottidis. The pharynx itself is shortened and drawn forward by the contraction of the palato-pharyngei muscles; the soft palate is also raised and made tense, thus cutting off the upper part of the pharynx and posterior nares, and forming an incline under which the bolus is passed into the pharynx. This passage is effected by the elevation of the hyoid bone and the base of the tongue, and the simultaneous contraction of the pillars of the fauces. The bolus is then seized and carried rapidly down past the larynx by the pharyngeal constrictors. The third stage of the act of deglutition is due to the peristaltic contractions of the esophagus." The nerve centers are in the medulla.
2. *Tetanic muscular contraction* is produced in a muscle when it is stimulated so rapidly that it has no time to relax between one stimulus and the next; the result is a prolonged, steady contraction. During contraction the following changes take place in a muscle: (1) It becomes shorter and thicker, but the volume remains the same. (2) It consumes oxygen. (3) It sets free carbon dioxide. (4) It forms sarcolactic acid. (5) It becomes acid in reaction. (6) It becomes more extensible and less elastic. (7) There is an increase in heat production, and consequently a rise of temperature. (8) The electrical reaction becomes relatively negative.

Rigor mortis is the condition of rigidity, or contraction, into which the muscles of the body pass after death. It is of gradual onset, and begins at a period varying from about fifteen minutes to about six hours. Usually the muscles of the jaw are first affected, then those of the neck, trunk, upper limbs, and lower limbs, in order. The muscles become short, opaque, and rigid; heat and carbon dioxide are given out; acid phosphates and sarcolactic acid are formed, and so an acid reaction is developed; and the muscles lose their irritability to stimuli.

3. *Blood pressure* is the pressure of the blood due to the ventricular systole, the elasticity of the arterial walls, and the resistance of the capillaries. The normal arterial blood pressure varies; the systolic pressure being about 120 to 150 mm. of mercury, and the diastolic from about 90 to 120 mm. of mercury. Blood pressure is *maintained* by the contraction of the heart, the peripheral resistance, and the elasticity of the arterial walls. Blood pressure:

MAY BE RAISED.	MAY BE LOWERED.
1. By the heart beating more quickly.	1. By the heart beating more slowly.
2. By the heart beating more powerfully.	2. By the heart beating more feebly.
3. By contraction of the arterioles.	3. By dilatation of the arterioles.
	4. By deficient supply of blood to the left ventricle.

Blood pressure is estimated by a sphygmomanometer.

4. Rays of light from external objects are focused on the retina, and start nerve impulses which are transmitted by the optic nerve and optic tract to the center for sight in the cortex of the brain. The following diagram will show how the image is formed on the retina.

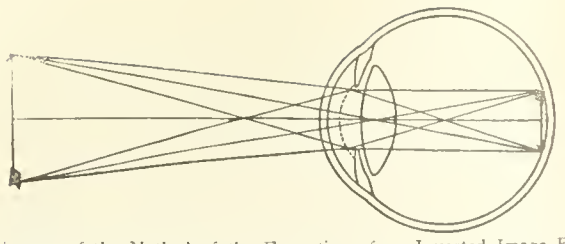

Diagram of the Method of the Formation of an Inverted Image Exactly focused upon the Retina. The dotted line is the ideal surface of curvature.

Myopia is a condition in which the antero-posterior axis of the eye is abnormally long, and parallel rays are focused in front of the retina.

Hypermetropia is a condition in which the antero-posterior axis of the eye is abnormally short, and parallel rays are focused behind the retina.

5. "The continued use of tobacco, by smoking or chewing it to *excess,* produces granular inflammation of the fauces and pharynx, atrophy of the retina, dyspepsia, lowered sexual power, sudden faints, nervous depression, cardiac irritability, and occasionally angina pectoris. Used by the young, it hinders the development of the higher nerve centers and impairs the nutrition of the body by interfering with processes of digestion and assimilation."—(Potter's *Materia Medica,* etc.)

6. *Male organs of reproduction:* Testes, vasa deferentia, seminal vesicles, ejaculatory ducts, Cowper's glands, prostate gland, and penis.

Female organs of reproduction: Labia majora, labia minora, clitoris, vagina, uterus, Fallopian tubes, and ovaries. The ovum is usually impregnated in the Fallopian tubes.

7. Pneumogastric nerve. *Superficial origin:* Groove between restiform and olivary bodies. *Deep origin:* Nuclei in floor of fourth ventricle. *Distribution* is shown by the names of the branches: Meningeal, auricular, pharyngeal, superior and inferior laryngeal, cardiac, pulmonary, esophageal, and gastric. *Function:* It supplies (1) *motor* influence to the pharynx and esophagus, stomach, and intestines, to the larynx, trachea, bronchi, and lungs; (2) *sensory* and, in part, (3) *vasomotor* influence, to the same regions; (4) *inhibitory* influence to the *heart;* (5) *inhibitory* afferent impulses to the *vasomotor center;* (6) *excito-secretory* to the salivary glands; (7) *excito-motor* in coughing, vomiting, etc.

8. When blood is withdrawn from the blood-vessels of the living body it first becomes viscid, then sets, and is converted into a jelly-like mass. This is due to the formation of fibrin. The jelly contracts, forming the clot; and at the same time the serum is squeezed out from the clot. Various circumstances and conditions will hasten or delay the process of coagulation. In man, the blood generally becomes viscid in from two to three minutes; it forms the jelly-like mass in from five to six minutes; a few minutes later the serum begins to appear; and the whole process is completed in from twenty-four to thirty-six hours. The clot then floats in the serum. The process is thus summed up by Halliburton: In the plasma a proteid substance exists, called Fibrinogen. From the colorless corpuscles a nucleo-proteid is shed out, called Prothrombin. By the action of calcium salts prothrombin is converted into fibrin ferment, or Thrombin. Thrombin acts on fibrinogen in such a way that two new substances are formed: one of these is unimportant and remains in solution; the other is important, viz., Fibrin, which entangles the corpuscles and so forms the clot.

9. The motor areas are located and arranged on the cerebral cortex, immediately in front of the fissure of Rolando. At the upper part of the convolutions in front of this fissure are the areas connected with the movements of the lower extremities; then from above downward are located the centers for movements of the trunk, shoulders, arms, wrists, fingers, face, lips, tongue, and larynx and pharynx.

10. The *red blood corpuscles* are biconcave discs about 1-3200 of an inch in diameter; they are nonucleated, and there are about 4,500,000 or 5,000,000 of them in each cubic millimeter of blood. They are elastic and soft, and their shape is changed by pressure, but is promptly regained on the removal of the pressure. Their color is yellowish. They contain hemoglobin.

MATERIA MEDICA AND THERAPEUTICS.

1. *Drugs* are all remedial substances used for the treatment of disease.

Cerates are preparations like ointments, but contain wax and are of a finer consistence.

Collodions are liquid preparations containing a solution of pyroxylon in alcohol and ether.

Confections are preparations made up with sugar or honey or some similar substance.

2. Motor depressants are agents which lower the functional activity of the spinal cord and motor apparatus, or even paralyze them. *Examples:* Curare, aconite, tobacco.

3. Mydriatics are agents which cause the pupil of the eye to dilate. *Examples:* Atropine, hyoscyamine, duboisine.

4. Arsenic. *Two preparations:* Arsenic trioxide and liquor potassii arsenitis. *Physiological action:* Escharotic; irritant, tonic; increases cardiac action, respiratory power, intestinal secretions, and peristalsis; produces edema, itching, diarrhea, epigastric pain, irritable and feeble heart. *Official antidote:* Freshly prepared solution of ferric hydroxide.

5. Mercury. (1) Hydrargyri chloridum mite (calomel), dose gr. ss to x; used in syphilis, as a laxative or purgative, in congested or cirrhotic liver, in diarrhea, and as a diuretic. (2) Hydrargyri chloridum corrosivum (corrosive sublimate), dose gr. 1/60 to 1/30; used as an antiseptic, disinfectant, antiparasiticide, in syphilis, interstitial nephritis. (3) Liquor arseni et hydrargyri iodidi (Donovan's solution), dose ℥v; used as an alterative.

6. Nux vomica. (1) Tincture, dose ℥v-xx. (2) Strychnine sulphate, dose gr. 1/60 to 1/30. *Physiological action:* Strychnine is a bitter tonic, stimulates appetite, secretion, and digestion, increases peristalsis, stimulates the vasomotor centers, and so raises arterial tension, stimulates both accelerator and inhibitory nerves of the heart. All the functions of the spinal cord are exalted by strychnine, reflex, motor, vasomotor, and sensory. Large doses cause dilated pupils, irregular and jerky respiration, increased reflexes. *Therapeutic indications:* As a general tonic or bitter; in indigestion, cardiac depression, impaired peristalsis, pneumonia, phthisis, amenorrhea, dysmenorrhea, impotence, some forms of paralysis, chorea, epilepsy, neuralgia, alcoholism, and urinary incontinence.

7. Chloral. *Source:* It is an aldehyde, formed by the action of chlorine on alcohol. *Dose* of chloral hydrate, gr. xv. It is *used* to produce sleep, provided no pain is present.

8. Salol. *Dose:* gr.vij. *Indications:* As a disinfectant, in inflammation of the mouth and pharynx, in cystitis, as an intestinal antiseptic in typhoid fever, in muscular rheumatism, in intestinal indigestion and fermentation, in cholera.

9. *Prescription writing:* "Although prescriptions in good English are preferable to those written in incorrect or badly abbreviated Latin, those written in the classic style should be governed by the following rules: The name of the patient and the date should be placed at the top. The sign ℞, which is the abbreviation of the Latin word *Recipe,* and signifies 'Take' or 'Take thou,' should be placed in the upper left corner. The names and quantities of the ingredients then follow, and the names should be written in Latin, in the genitive case usually. The directions to the compounder should be in Latin, but the directions to the patient should be written in English. The prescription is completed by the name and address of the prescriber. The quantities of the drugs may be expressed in apothecaries' weights or in the metric system."—(Gould and Pyle's *Pocket Cyclopedia.*)

Example: For Mrs. Smith. June 1, 1907.

℞.

Quininæ hydrobromatis.
Sodii benzoatis.
Caffeinæ citratæ, āā gr. xx.

Misce, et fiat massa in pilulas no. xx dividenda.

Signa: Take one three times a day.

John Doe, M.D., 13 West 23d Street.

10. *Emmenagogues* are agents which promote the menstrual flow; they act by stimulating the uterine muscles, and also by stimulating the nervous system; they are also oxytocic. They are used in cases of amenorrhea or scanty menstruation. *Examples:* Tansy and apiol.

BACTERIOLOGY AND HYGIENE.

1. *Bacteria* are unicellular vegetable organisms, devoid of chlorophyl, and multiplying by fission.

Pathogenic means causing disease.

Saprophytic means living on dead organic matter.

Leucocytes are white blood corpuscles (or cells resembling them).

Phagocytes are cells (such as leucocytes) which have the power of devouring or destroying microbes or other cells.

2. An *antiseptic* is an agent which prevents or restrains putrefaction; as mercuric chloride.

A *disinfectant* is an agent which destroys the germs causing infection; as heat.

3. *Toxins* are the poisonous products of pathogenic bacteria, or of ptomains, or of leucomains.

Antitoxins are substances formed in the body, of a protective character, and capable of rendering inert the poisonous products of bacteria.

Leucomains are basic, nitrogenous substances which are produced in living vertebrate organisms.

Ptomains are the putrefaction products of dead animal tissues or fluids.

4. "*Infection* signifies the entrance of pathogenic microorganisms into the living body; the condition produced by their subsequent propagation and other vital activities is called an infectious disease, or simply an infection."—(French.)

5. "*Heredity* as a predisposing factor in disease is probably less important than was formerly believed, but undoubtedly plays a part in many conditions. By hereditary predisposition is designated abnormal weakness of resistance transmitted from the mother or father to the offspring. There may be congenital weakness that is not definitely hereditary, as it is more or less accidental—that is, not the outcome of tendencies of the same kind (latent or active) in the parent. Heredity may be *direct* or *immediate*—that is, from the parent (himself or herself presenting the condition) to the offspring—or *remote*, as in cases in which the hereditary trait is *latent* in the parent. One or several generations may thus be free from certain diseases or tendencies which reappear in later generations. This return to conditions present in remote ancestors has been likened to *atavism* in the Darwinian sense. In some cases hereditary traits are conveyed from the male parent to the male children, or from the female parent to the female offspring; in other cases there is crossed transmission. A peculiar form of heredity is seen in hemophilia and in some other diseases, which are transmitted through the female members of a family, who generally remain unaffected, to the male offspring. Hereditary traits sometimes predispose to a number of allied affections. This is particularly striking in the case of the neuropathic heredity, in which various forms of nervous diseases may appear alternately or irregularly in members of an affected family."—(Stengel's *Textbook of Pathology.*)

6. *Patients should not be sent to a high altitude* who are suffering from: Heart disease, emphysema, chronic bronchitis, Bright's disease, pulmonary hemorrhage, or chronic rheumatism.

7. A rheumatic patient may be recommended to a climate which combines warmth and dryness, such as a desert climate.

8. "Fair death rates are 9 to 16 per 1,000 in rural districts and small villages; 14 to 18 per 1,000 in towns of 5,000 to 20,000; 17 to 20 in cities of 25,000 to 100,000; and 18 to 21 in cities of over 100,000."—(Egbert's *Hygiene and Sanitation.*)

9. The most sanitary method of disposing of a city's garbage is by cremation. Sewage should be disposed of through plumbing fixtures and pipes, and finally by bacterial methods.

10. *Typhoid fever may be communicated by:* Food, milk, water, oysters; dust; soiled hands, clothing, instruments or utensils; or anything that has become contaminated with the feces, urine, or vomitus of one affected with typhoid.

CHEMISTRY AND MEDICAL JURISPRUDENCE.

1. Carbon exists in three allotropic forms: Diamond (in octahedral crystals), graphite (in imperfect crystals or amorphous), and amorphous. The diamond is the hardest substance known, is brittle, a good refractor of light, and a bad conductor of heat and electricity. Graphite is soft, and a good conductor of electricity. Amorphous carbon is met with in many forms. Carbon is insoluble in the ordinary solvents, and is only slightly soluble in molten cast iron; it unites directly with very few elements, but indirectly with many. It is found, in combination, in all plants and animals; is much used for fuel and food.

2. *Three standard solvents:* Water, alcohol, and ether.

3. *Chemical incompatibles* are substances which, in combination, would produce chemical decomposition, or explosion, or some undesired chemical reaction. *Examples:* Mixing acids with bases, tannic acid with gelatin or alkaloids, or chromic acid with organic substances.

4. *Hydrogen sulphide* may be detected by its odor of rotten eggs; also, it will discolor black or brown a paper that has been moistened with solution of lead acetate.

Carbon dioxide forms a white precipitate when it is bubbled through lime water.

Laughing gas is colorless, and does not change color on exposure to air, and is thus different from the other oxides of nitrogen; it will rekindle a glowing splinter of wood, and thus resembles oxygen, from which it may be distinguished as follows: Add a little nitrogen dioxide; it turns red with oxygen, but produces no effect on laughing gas.

Ammonia may be detected by its characteristic odor, also by the dense white fumes produced on inserting a glass rod moistened with strong hydrochloric acid into the gas.

5. *Oxygen* can be made by decomposing potassium chlorate by heat:

$$2KClO_3 + \text{heat} = 2KCl + 3O_2$$

Hydrogen, by the action of zinc on cold dilute sulphuric acid:

$$Zn + H_2SO_4 + xH_2O = xH_2O + ZnSO_4 + H_2$$

Chlorine, by decomposing hydrochloric acid by manganese dioxide:

$$MnO_2 + 4HCl = MnCl_2 + 2H_2O + Cl_2$$

Ammonia, by heating a solution of ammonium hydroxide:

$$(NH_4)OH + \text{heat} = H_2O + NH_3$$

6. *From coal tar are obtained:* (1) *Acetanilid,* used to reduce fever, to relieve pain, to prevent or relieve epileptic seizures, and as an antiseptic dressing for wounds, ulcers, burns, chancroids, etc. (2) *Phenol.* Carbolic acid is used "as a disinfectant for surgical instruments, soiled linen, hospital apparatus, drains, privies, etc.; as an application for burns, carbuncle, endocervicitis, lupus, condylomata, and various other conditions; as an injection for leucorrhea and gonorrhea in the female; as a local anesthetic. Its antipruritic and parasiticidal qualities render it useful in many cutaneous affections; and it is employed locally in hay fever, influenza, and nasal catarrh. In the treatment of wounds it has been largely superseded by more powerful germicides. Internally: gastrointestinal irritation; malarial fever, typhoid fever, scarlet fever, and other zymotic diseases; influenza; by hypodermic injection in tetanus and bubonic plague."—(Wilcox, *Materia Medica.*) (3) *Salicylic acid,* used: "Externally as antiseptic and stimulating applications and for the checking of abnormal perspiration; also in parasitic and other skin diseases. Internally, rheumatic fever (in which it seems to act as a specific); gout; migraine; sciatica; diabetes; cholelithiasis."—(Wilcox, *Materia Medica.*) (4) *Salol* (or phenyl salicylate), used as a disinfectant, in inflammation of the mouth and pharynx, in cystitis, as an intestinal antiseptic in typhoid fever, in muscular rheumatism, in intestinal indigestion and fermentation, in cholera.

7. *Marsh's test for arsenic:* This depends on the fact that arsenic hydride is formed when nascent hydrogen acts on a compound of arsenic.

$$H_3AsO_3 + 3H_2 = AsH_3 + 3H_2O.$$

A small flask fitted with thistle funnel and a delivery tube, as for the production of hydrogen, is used; pure zinc and hydrochloric acid are introduced, and after a short time the hydrogen is ignited. It is advisable to cover the flask with a cloth before igniting the gas, as an explosion may happen unless the air has all been driven out. If the materials are pure the hydrogen flame gives no deposit upon a piece of cold porcelain brought into it, but commercial zinc usually contains arsenic. When the purity of the gas is proved, a little solution of arsenic may be poured down the thistle funnel, which will produce a more rapid evolution of gas, and the flame will become larger and perceptibly colored. A piece of cold porcelain depressed upon the flame will be covered with a deposit of metallic arsenic. The films of arsenic are metallic looking in the thicker places, brownish near the edges; they are easily volatilized by heat, and dissolve in solution of bleaching powder. A portion of the glass tube from which the gas is burned should be heated to redness; the gas decomposes, and a deposit of arsenic appears on the tube, which may be identified in a similar way, or may be converted into crystals of oxide by cautious sublimation in an open tube. —(Fisher's *Elementary Chemistry.*)

8. *Signs of death from drowning:* Froth at nostrils and mouth; pallor and goose-skin; maceration of epidermis of palms of hands and soles of feet; sand or mud may be under the nails or in the hands; water and foreign matter are generally in the stomach and also in bronchi; lungs are swollen and emphysematous; the right side of the heart is engorged and the left side is empty; the liver is engorged.

9. "*Gunshot wounds* differ from ordinary punctured and penetrating wounds in that the tissues immediately surrounding the canal through which the projectile passed

are so contused and injured as to result in their death. For this reason the canal resulting from a gunshot wound does not heal by first intention, and is particularly liable to infection and sloughing. Gunshot wounds, on account of the velocity of the projectile and the degree of propelling force, are associated with a greater amount of shock than would result from the same wound from other causes."—(Dwight's *Epitome of Medical Jurisprudence.*)

10. *Ante-mortem* wounds generally show hemorrhage, coagulated blood, eversion of the edges and retraction of the sides; pus, gangrene, or beginning cicatrization also indicate that the wound was inflicted during life. *Post-mortem wounds,* the reverse of all this.

PRACTICE OF MEDICINE AND PEDIATRICS.

1. See French's "Practice of Medicine" (1910), pages 577, 582, 587, 593, 598, 603, 605, and 606; or Osler's "Practice of Medicine" (1909), pages 785, 792, 796, 802, 804, 808, 811, and 813.

2. See French's "Practice of Medicine" (1910), pages 1030 and 1032; or Osler's "Practice of Medicine" (1909), pages 1039 and 1040.

3. See French's "Practice of Medicine" (1910), pages 218 and 221; or Osler's "Practice of Medicine" (1909), pages 210 and 212.

4. See French's "Practice of Medicine" (1910), page 791.

5. Spotted fever may be either typhus, cerebrospinal meningitis, or tick fever. See French's "Practice of Medicine" (1910), pages 122, 127, 139, 149, 452, and 454; or Osler's "Practice of Medicine" (1909), pages 105, 109, 158, 164, and 368.

6. See French's "Practice of Medicine" (1910), pages 481 and 486; or Osler's "Practice of Medicine" (1909), pages 28 and 30.

7. See French's "Practice of Medicine" (1910), pages 723, etc.; or Osler's "Practice of Medicine" (1909), pages 434, etc.

8. *Peculiarities of digestive organs in babies.*—There are no teeth; saliva is scanty and is deficient in ptyalin; the stomach lies nearly vertical, and its fundus is but slightly developed; the duodenum is a digestive reservoir where the food from the stomach is mixed with the secretions from the liver and the pancreas; the intestines are relatively long, particularly the descending colon and sigmoid flexure: the liver is large.

9. *Ague* is malaria. Children are very susceptible; anemia is common, the spleen may be much enlarged, the invasion may be insidious, cerebral symptoms are common, and gastrointestinal disorders may occur. Children tolerate quinine well, and so it may be given in relatively large doses.

10. See French's "Practice of Medicine" (1910), pages 780, etc.; or Osler's "Practice of Medicine" (1909), pages 497, etc.

OBSTETRICS AND GYNECOLOGY.

1. See PHYSIOLOGY AND HISTOLOGY, 6.

In the nulliparous adult the uterus is about three inches long, about two inches wide at the upper part, and about one inch thick. The uterus lies between the rectum behind and the bladder in front; it is below the abdominal cavity, and above the vagina. Its position is one of slight anteflexion, with its long axis at right angles to the long axis of the vagina. The anterior surface of its body rests on the bladder, and the cervix points backward toward the coccyx. The uterus is not fixed, but moves freely within certain limits. It is held in place by ligaments—broad ligaments, round ligaments, vesicouterine and rectouterine. The arteries are the uterine and ovarian; the nerves are from the uterovaginal plexus, the hypogastric plexus, and the vesical plexus.

2. *Ascites.*—Absence of the signs of pregnancy; the abdomen is distended, but the shape varies with the position of the patient; on lying down there is bulging at the sides, the tumor fluctuates, and percussion shows dullness in the flanks, with resonance in the median line, but the dullness varies with the position of the patient.

Ovarian cyst.—Absence of the chief signs of pregnancy; there may be the characteristic facies; the tumor is soft, fluctuating, is more to one side, and does not show fetal signs.

Pregnancy.—The tumor is hard and does not fluctuate, is situated in the median line, and may give fetal heart sounds and movements; the cervix is soft, and the other signs of pregnancy are present. The rate of growth of the tumor and the general condition of the patient's health may also help in arriving at a diagnosis.

5. See Williams' "Obstetrics" (1909), page 804; or Hirst's "Obstetrics" (1909), page 433.

6. See Williams' "Obstetrics" (1909), pages 883, etc.; or Hirst's "Obstetrics" (1909), pages 732, etc.

7. See Williams' "Obstetrics" (1909), pages 658, etc.; or Hirst's "Obstetrics" (1909), pages 439, etc.

8. See Williams' "Obstetrics" (1909), pages 599, etc.; or Hirst's "Obstetrics" (1909), page 943.

9. The INDICATIONS FOR HYSTERECTOMY are given as follows: *For the abdominal operation:* All solid or cystic tumors of the uterus; cancer; uterine rupture during labor; certain conditions of puerperal sepsis; pregnancy complicated by pelvic deformity, cancer, or other serious obstacle to the passage of the child; uterine prolapse or inversion, and incidentally as a step in the removal of complicated suppurative conditions of the uterine appendages.

For the vaginal operation: Bilateral suppurative conditions of the appendages; prolapse, cancer, pregnancy with cancer before the sixth month; certain septic conditions of the uterus; certain rare conditions which may require the ablation of a small movable uterus.

For the combined operation: Cancer, certain complicated fibroids; failure to secure hemostasis from below.—(From *Reference Handbook of the Medical Sciences.*)

The relative advantages and disadvantages of the abdominal and vaginal routes in pelvic surgery are thus summarized by Dudley (*Diseases of Women*):

Advantages of the abdominal route: (1) A larger field is open for operation; (2) the operator may see what he is doing instead of depending largely on touch; (3) diagnosis of unsuspected conditions and complications is much easier; (4) the abdominal section is adapted to large tumors and pus sacs, and to conditions high in the pelvis; (5) the appendages may be removed with better chance of avoiding rupture of a pus sac; (6) there is less danger of wounding intestines, bladder, or ureters and greater facility in the control of hemorrhage; (7) the frequent concurrence of appendicitis and other abdominal lesions with pelvic disease and the impossibility of reaching them by the vagina; (8) it gives more light and more space for conservative work.

Advantages of the vaginal route: (1) It gives better drainage, and is therefore specially adapted to cases of vesical or intestinal fistulæ; (2) it avoids abdominal scar and risk of ventral hernia; (3) it is suitable for cases of small tumors without high adhesions; (4) when properly performed it lessens the danger from shock, and is therefore suitable to cases of extreme pelvic infiltration which are inoperable, because too dangerous, by the abdominal route; (5) it involves less handling of the intestines, and therefore less consequent danger of intestinal adhesions; (6) recovery is less complicated and more rapid.

Unfortunately, the vaginal route is, for at least a very large proportion of cases, impracticable. The long, narrow virgin vagina or the vagina which has become contracted from senile atrophy may render the field of operation almost inaccessible. A very large uterus with exceptionally short, thick, broad ligaments and greatly enlarged appendages, with adhesions extending beyond the reach of the finger, may also be difficult or impossible to manipulate through the vagina. Under such conditions the abdominal route is much safer.

10. Pruritus vulvæ may be *caused by:* Parasites; diseases of the vulva, as inflammation, edema, vegetations, congestion, irritating discharges, lack of cleanliness, diabetic urine; it may also be of nervous origin, or idiopathic. *Treatment* consists in removing the cause, if possible; cleanliness, fresh air, tonics, and general attention to hygiene; local applications of solution of bichloride of mercury 1:2,000; or carbolic acid, 1:100; or lead and opium; dusting powders of bismuth subnitrate, calomel, or zinc oxide are also useful.

SURGERY.

1. PYOTHORAX (EMPYEMA). *Symptoms:* Fever, sweats, chill, diminished breath sounds and vocal fremitus, impaired mobility of chest, dullness on affected side, heart displaced to opposite side, leucocytosis.

Diagnosis is made by aspiration, showing the fluid to be pus.

Treatment: Aspiration, drainage, irrigation, resection of ribs (Estlander's operation) or resection of chest wall (Schede's operation) and see Rose and Carless' "Surgery" (1908), page 928; or Da Costa's "Surgery," page 774.

2. See Rose and Carless' "Surgery" (1908), pages 1325 and 1310; or Da Costa's "Surgery" (1908), pages 1033 and 1047.

3. Iritis. *Causes:* Syphilis, rheumatism, gonorrhea, gout, diabetes, leprosy, scrofula, tuberculosis, injury, transmission from the eye. *Symptoms:* Pain, photophobia, small pupil, ciliary congestion, discoloration of iris, exudate in anterior chamber. *Surgical Treatment:* Causal abstraction of blood from temples, paracentesis, and iridectomy.

4. See Da Costa's "Surgery" (1908), page 245.

5. See Rose and Carless' "Surgery" (1908), page 1041; or Da Costa's "Surgery" (1908), page 853.

6. See Rose and Carless' "Surgery" (1908), page 1266; or Da Costa's "Surgery" (1908), page 1201.

7. See Rose and Carless' "Surgery" (1908), page 764; or Da Costa's "Surgery" (1908), page 702.

8. *The early symptoms of tuberculous disease of the hip* are: Night cries (in a child); lameness in the morning; a slight limp; tendency to become tired on slight exertion; wasting; spasm; pain; swelling; and deformity (either real or apparent).

It may be mistaken for: Caries of the spine, sacroiliac disease, infantile paralysis, congenital dislocation of the hip, abscess or bursitis in the gluteal region, abscess in neck of femur.

9. See Da Costa's "Surgery" (1908), page 894.

10. The *various dislocations of the shoulder joint* are: (1) Subcoracoid—forward, inward, and downward. (2) Subglenoid—downward, forward, and inward. (3) Subspinous—backward, inward, and downward. (4) Subclavicular—forward, inward, and upward.

For the subcoracoid Kocher's method of reduction is: to flex the forearm, press the elbow to the side, rotate the arm outward. Bring the arm forward and upward to a right angle with the body, then rotate inward, while the elbow is brought down over the body so that the fingers sweep the opposite shoulder.

SPECIAL MEDICINE.

1. See French's "Practice of Medicine" (1910), page 607; or Osler's "Practice of Medicine" (1909), page 704.

2. On *inspection of the chest* there should be noted: the general shape, size, symmetry, nutrition, and muscular development; expansion; and rhythm, frequency and force of movements; pulsations, and tumors.

On *palpation of the chest* there should be noted: tenderness, expansion, fremitus, pulsations, swellings or growths, and warmth and moisture of the skin.

3. See French's "Practice of Medicine" (1910), pages 95, 126, 146, 306, 322, and 329; or Osler's "Practice of Medicine" (1909), pages 87, 120, 136, 143, and 162.

"*Erysipelas* sometimes extends to the skin of the eyelids, causing their closure, or is followed by desquamation, with loss of the lashes. It is sometimes accompanied by other ocular disturbances, as purulent dacryocystitis, corneal abscess, and purulent iridochoroiditis. (Optic atrophy has also been observed.)

"*Measles* is usually preceded in children by a period in which there is a marked tendency to close the eyes and sleep. There is very often a marked conjunctivitis before the eruption. As the rash appears, photophobia, lacrymation, blepharitis, and tiring of accommodation follow, and soon an inflammatory condition of the conjunctiva may be detected.

"*German measles* is characterized by the occasional appearance of the rash on the lids.

"*Scarlet fever* is seldom associated with any diseases of the eye during the height of the affection, but during convalescence corneal ulcerations and inflammations are not infrequent. Renal changes are followed by the characteristic eye-ground alterations.

"*Smallpox* is not only liable to be accompanied by keratitis, iritis, etc., but the lesions themselves of smallpox are not uncommonly situated upon the cornea, causing irreparable damage to the structure. The same conditions are likely to take place in *vaccinia* and *varicella*.

"In *typhoid* and *typhus* coma vigil frequently occurs. Dilatation of the pupil, paresis of accommodation, with asthenopia and extraocular muscle palsies have been observed as sequels. Anesthesia of the cornea, phlyctenular ulcers, iritis, retinal hemorrhages, and optic neuritis are seen during the height of the disease. A peculiar dryness of the conjunctiva often occurs."—(From Fox's *Ophthalmology.*)

4. "*Foreign bodies in the eyeball* may be located by focal illumination, the ophthalmoscope, or the Röntgen rays. Foreign bodies sometimes remain quiescent in the eye without doing harm, but are always a source of danger. Extraction should first be attempted by the magnet or forceps under anesthesia and with antiseptic precautions, preferably through the wound of entrance. If this fails, enucleation may be indicated, as sympathetic irritation or inflammation is likely to appear."—(Gould and Pyle's *Pocket Cyclopedia*).

5. "Diphtheritic rhinitis may accompany faucial infection or precede the infection. It is more often observed in children. Symptoms of the disease are a profuse, slightly fetid discharge from the nose, general debility, enlarged cervical glands, rapid pulse, slight elevation of temperature. The pseudo-membrane adheres to the mucous surface and upon removal leaves bleeding points. The Klebs-Löffler bacillus is always present. Albuminuria may also be present. Local palsies may follow as in faucial diphtheria. *Treatment.*—The local treatment consists in irrigation with warm solution of Dobell's followed by dusting with trypsin. Antitoxin 1-500 c.c. should be injected, followed by the administration of chloride of iron in fifteen-drop doses four times daily. Purgation should be encouraged by the hourly administration of calomel, one-tenth-grain doses. The patient should be isolated."—(Kyle's *Diseases of Ear, Nose, and Throat.*)

6. See Rose and Carless' "Surgery" (1908), page 866.

7. There is some confusion in the terminology of the diseases in this question. Catarrhal croup is undoubtedly the false croup, or croup without a membrane. Membranous laryngitis may be membranous or true croup, or diphtheria; that is, the membrane may contain no pathogenic bacteria, or it may contain the Klebs-Loeffler bacillus, or *Streptococcus pyogenes*, etc. See French's "Practice of Medicine" (1910), pages 188, 191, and 663; or Osler's "Practice of Medicine" (1909), pages 205 and 599.

8. In *paralysis of the vocal cords:* The nerves involved are the superior laryngeal and the recurrent laryngeal (both branches of the pneumogastric nerve).

The following oft-quoted table from Glowers shows the symptoms, laryngoscopic picture, and lesions:

SYMPTOMS.	SIGNS.	LESIONS.
(*a*) No voice; no cough; stridor only on deep inspiration.	Both cords moderately abducted and motionless.	Total bilateral palsy.
(*b*) Voice low-pitched and hoarse; no cough; stridor absent or slight on breathing.	One cord moderately abducted and motionless, the other moving freely and even bevond the middle line in phonation.	Total unilateral palsy.
(*c*) Voice little changed; cough normal; inspiration difficult and long, with loud stridor.	Both cords near together, and during inspiration not separated, but even drawn nearer together.	Total abductor palsy.
(*d*) Symptoms inconclusive; little affection of the voice or cough.	One cord near the middle line, not moving during inspiration; the other normal.	Unilateral abductor palsy.
(*e*) No voice; perfect cough; no stridor or dyspnea.	Cord normal in position and moving normally in respiration, but not brought together on an attempt at phonation.	Adductor palsy.

—(From Hughes' *Practice of Medicine.*)

Treatment consists in removal of the cause (where possible): tonics (such as strychnine), and electricity have been used with some success.

9. See Osler's "Practice of Medicine" (1909), page 1036.

10. See French's "Practice of Medicine (1910), page 1083; or Osler's "Practice of Medicine" (1909), page 889.

Regeneration of Epithelium in Superficial Duodenal Ulcers.—Helmholz states that superficial ulcers of the duodenum may be healed over by epithelium growing from Brunner's glands.—*Virchow's Archiv.*

Foudroyant Puerperal Sepsis Caused by Colon Bacillus.—Pruska describes a case of peracute postabortal sepsis caused by the colon bacillus, in which death occurred in twenty-three hours after the beginning of the septic manifestations.—*Casopis Lekaruo Ceskych.*

Medicolegal Notes.

Communications to Physician Only Privileged by Statute—Relation of Patient and Physician Must Exist.—The testimony of a physician was not excluded at common law. It is only privileged by the New York statute on the subject (Code Civ. Proc. §834) when his information is "acquired in attending a patient in a professional capacity" and where such information "was necessary to enable him to act in that capacity." The burden is upon the party seeking to exclude the testimony of a physician under this section to bring the case within its provisions. If the physician never attended the defendant (the case in question was one of murder, where the defense was insanity) in a professional capacity, and never obtained information from him to enable him to prescribe in such professional capacity, he can testify the same as any other person. In such a case the seal of confidence existing by virtue of the statute between physician and patient and made necessary to obtain the fullest information in no way applies. Where a physician is sent to a jail by the district attorney to make an examination of the prisoner's mental and physical condition the relation of patient and physician as contemplated by the section does not exist, and the prisoner is not thereby compelled to furnish evidence against himself. In such a case the physician may testify as to the prisoner's condition.—People v. Austin, New York Court of Appeals, 93 N. E. 57.

Malpractice—Degree of Care and Skill Required from Surgeon—What Defendant Is Entitled to Show.—A physician or surgeon, by taking charge of a case, impliedly represents that he possesses, and the law places upon him the duty of possessing, that reasonable degree of learning and skill that is ordinarily possessed by physicians and surgeons in a locality where he practises and which is ordinarily regarded by those conversant with the employment as necessary to qualify him to engage in the business of practising medicine and surgery. This principle was applied in an action for alleged malpractice at the instance of a young woman who, on the advice of a physician, went to a hospital and was operated upon by one of the surgeons. Later on the same day a minor operation, mainly for the purpose of drainage, was required, and some time later a second incision was made for the same purpose. Still later one of these incisions was opened to secure as far as possible some of the spots found to have been weakened by the infection found upon the occasion of the first operation. The action was for "negligence, carelessness, and unskillfulness" in conducting the operations. It was not contended that the defendant did not possess the requisite learning, skill, and experience. In addition he must "use reasonable care and diligence in the exercise of his skill and the application of his learning to accomplish the purpose for which he was employed. He is under the further obligation to use his best judgment in exercising his skill and applying his knowledge." The complaint alleged that the defendant did not use reasonable care. An examination of the whole case satisfied the court either that the verdict (which was for the plaintiff) was against the evidence, or that it rested entirely upon the charge of negligence and carelessness in the after-care of the patient, a charge not embraced in the complaint. As to the condition of affairs which the defendant found when he examined and operated upon plaintiff, and as to the nature of the operations actually performed, the court did not hold any of the evidence to be of any value except that of the defendant himself and his assistants, for they alone saw and knew the conditions and operations. As to whether or not the operations as performed were proper and in accordance with the requirements of professional skill, the court was obliged to rely upon the evidence of experts having special knowledge of such subjects. The burden of establishing affirmatively either want of skill or negligence in the care and attention of a patient must be assumed by him. If the jury were justified in accepting the plaintiff's version of defendant's neglect after the operation and rejecting the contradictory evidence for the defendant the court held that the verdict should not be allowed to stand, being excessive. The court held that it was error not to permit the defendant to answer a question whether in performing the operation it did not, in his judgment, become necessary to separate the tissues from the sac in which the pus was found, thus preventing him from showing that he exercised his best judgment. It was also error not to allow him to answer the question, "What instructions did you leave with the hospital staff of physicians or nurses with reference to the care of the patient?"—Brown v. Goffe, New York Appellate Division, First Dept., 125 N. Y. Supp. 458.

RESECTION OF THE POSTERIOR ROOTS OF SPINAL NERVES TO RELIEVE PAIN, PAIN REFLEX, ATHETOSIS, AND SPASTIC PARALYSIS—DANA'S OPERATION.*

By ROBERT ABBE, M.D.,
NEW YORK,
SURGEON TO ST. LUKE'S HOSPITAL.

It is more than twenty-two years since Dr. C. L. Dana asked me if I were willing to perform for him an operation which had not heretofore been done and which he believed offered relief to a patient then suffering violent reflex neuralgic pains of the right arm, with muscle contraction associated with the spasms of pain, who already had had nerve stretching and amputation at the upper humerus by Dr. Bull with no abatement of pain. He conceived that the operation of "cutting the posterior roots within the dura would cause ascending degeneration and destroy the sensory tract, even into the spinal cord." The plans for this unique operation were made, as shown by Dr. Dana's letter to me in September, 1888. The operation was delayed by the patient's desire to have a neuroma of his stump resected first.

With every precaution I operated December 31, 1888, assisted by Dr. Bangs and in the presence of a number of distinguished neurologists and surgeons, performing Dana's operation. A full description was reported by me to the New York State Medical Society February 6, 1889, and published in its annals February, 1889. It was the forerunner of two others done by me under the same inspiration and published at length in a paper on the subject which I read in Boston and published in the *Boston Medical and Surgical Journal* October 1, 1896, with a review of operations by others up to date, a total of seven. The fact that my three patients lived under observation many years, and that I can contribute three recent cases of much interest, added to the wide attention now aroused, which has caused many operators to resort to it, cause me to make a short review of this now accepted operation.

Its legitimate scope, time and experience only will demonstrate. Pioneer work must be sifted of the cases which were imperfectly or wrongly done, while surgeons were feeling their way carefully along a new path. Few had dared to open the dura mater, release the arachnoid fluid and touch the cord itself up to the date proposed by Dr. Dana. It had always been known that to relieve neuralgia by resecting nerves, as in the cervical plexus, would paralyze the motor function beyond repair, hence the substitution of the more inefficient nerve stretching had been made. It had been demonstrated that the posterior roots were the sensory carriers and that nerve division eventuated in ascending degeneration.

Following the progressive boldness in opening the cerebral and spinal cavities, it was natural that some thinking student should propose just the operation devised by Dr. Dana. The first publication of my cases was February 9, 1889. This was the first published case in literature. On April 23 following there appeared a description of a case of persistent neuralgia of the leg, for which an amputation had been done without benefit, in which Mr. Bennett of London, under Mr. Horsley's advice, resected the posterior roots of the four lower and one upper sacral roots intradurally. This was done seven days prior to my first case, but three months after Dr. Dana had proposed it, and of which there had been much open discussion. During this period the patient operated on in England was subjected to amputation of his leg in hope of relief, and, failing that, was then suspected of syphilis, and during a month treated by mercurials, with no record of any idea of this operation. Failing in all relief, the operation that had been under discussion by Dr. Dana was done by Mr. Bennett. The patient was relieved of pain, but died on the twelfth day of cerebral apoplexy.

Much has been written about the technical methods of operating. It has been thought wisest by some to operate in two stages; first uncovering the dura and packing the wound open, then, after two days, slitting up the dura and dividing the roots. This has been thought desirable to avoid shock. This was done in my first case. While under ether some of the roots external to the dura were divided after identification by electric stimulation, but as the pain was not altered after waiting two days a series of roots within the dura was divided with the patient not anesthetized, but lying face downward. Opening the dura gave no pain, but handling the roots on a hook gave pain sense to the patient exactly corresponding to that felt before operation, notably in the eighth cervical, which would supply the palm. All my other operations have been done at one session and I prefer this, unless the patient's condition demands delay.

As now conducted, the accepted method is to separate the muscles from the laminæ on one side of the spinous processes under an incision alongside the spines. Then, to gnaw away the laminæ by rongeurs. This is the method first proposed by me after much work on spinal cases for tumors, pressure of fractures, etc., in 1888. One valuable modification has been made by Taylor; namely, to limit the removal of the bone to one-half lamina. This exposes the roots sufficiently for operation and preserves the support and protection from pressure of the other half lamina and spinous process. I have found this adequate in my last case and con-

*Read at a meeting of the Practitioners' Society of New York, January 6, 1911.

sider the technique now about perfect (Fig. 1). The operation is neither a bloody one nor tedious. The patient should be in a horizontal posture three-quarters turned upon his chest. A sharp pair of medium small rongeurs, bent partly on the flat, and preferably with a "gothic arch" cutting edge, such as I had made by Luer in Paris in 1884 and afterward by Ford in New York, is the best for vertebral work.

The posterior roots consist of four or five threads in each group, combining into one cord. Of these, at first all were divided after being raised from the cord on a tenaculum hook.

It was lately proposed by Bailey to make hemisection,* dividing only half or three-fifths of each group, thus modifying the sensory disturbing reflex, but not destroying the pain sense and consequent poor coordination of the motor function. This note has been the sequel of Sherrington's observation on monkeys, that when all the posterior roots were cut the animal refused to use his hand to

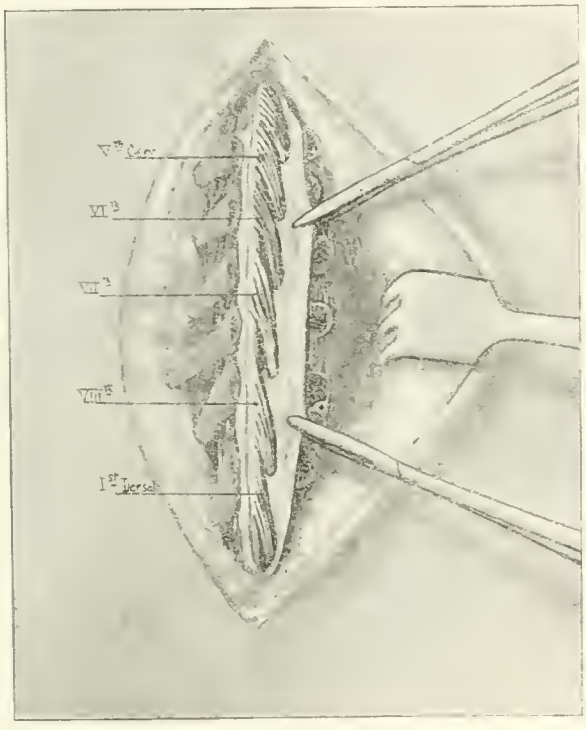

Fig. 1.

feed himself, though cortical stimulation showed perfect muscular function.

In my last case, to be narrated soon, I did the hemisection of each root with the happiest results. Förster has emphasized the wisdom of not cutting the posterior roots of a large number in continuity with the same idea of producing an incomplete anesthesia, but sufficient to control sensory reflex. With this idea he advises, if the legs are spastic, that instead of the lumbar 1st, 2d, 3d, 4th, 5th, and 1st sacral, one should omit the 4th, or the 1st, 3d, and 5th or the 2d and 4th, as seems wisest at the time. A better suggestion, however, is Taylor's, that half, or more, of each root contributing to the sciatic or the cervical plexus be divided; this preserves the nutrition of the remnant of the root and distributes the anesthesia evenly. This was most efficient in the last case I am about to report and will probably be accepted as the simplest and wisest method.

The condition of anesthesia following this operation is not uniform, on account of the overlapping distribution of the terminal filaments. There is rarely complete anesthesia. So many of the cases which have come to operation, where good section has been made, have had previous amputation of the limb that little accurate study has been made as yet. In working out the revised method also, partial and irregular section have given puzzling and paradoxical results. In the main, however, there has been a partial anesthesia of the skin corresponding to the roots supplying it.

In reporting my own five cases together, I will make the briefest mention of the three reported at length in the Boston paper in 1889.

Case I.—M. L. T., man of 40 years, suffered for two years from violent spasms of pain in the right arm, with spasmodic drawing up of the arm. This followed remotely from a shell wound of the shoulder during the war, but more immediately from a long exposure to cold in an ice refrigerator in which he was renewing a zinc lining. He had nerve stretching, nerve section, and, finally, a low and then a high amputation near the shoulder before he came to me. He had acquired morphine habit mildly. Dr. Seguin thought the pain "largely delusional, with an acquired morphine habit." All other neurologists regarding it as due to ascending neuritis with secondary morphine taking by necessity. The man gave evidence every five or ten minutes of sharp pain in the stump of the amputated arm, usually causing him to double over and grasp the stump with his left hand. When asked to describe an attack, he said it jumps and the stump draws to his side when the pain shoots into his hand and fingers, as if they were still on, and he could feel them all drawn up. He avers it keeps up during the night.

Drs. Dana, Starr and others diagnosed neuritis, and Dr. Dana devised the root section operation. It might be called "rhizotomy." I divided the 6th and 7th nerves on emerging from the dura, but inside vertebral canal. Pain was not measurably relieved. Two days later I laid the patient face down under a bright light and, on removing the packing from the wound, split up the dura, picked up and cut the posterior roots of the 7th and 8th nerves. As the 6th had been included in the section of the whole nerve outside the dura it was evident I had divided the sensory roots of the 6th, 7th, and 8th, which distributed to the hand and forearm. During the operation Dr. Dana frequently applied a fine electrical stimulation to the roots before cutting, thus identifying muscular distribution. This seems not to have been done in other cases, but may wisely be used in doubtful circumstances with safety. A one-cell dry pocket battery is sufficiently strong.

For ten days after operation the patient had more or less pain, but of different character. It no longer went down into the hand and arm nor up on the shoulder. I believe some of the postoperative pain can be attributed to pressure on the posterior aspect of the cord by the soft parts, where the bony arch had been wholly removed. In ten days he sat up and stopped his morphine entirely. In the third week he walked freely in the open air and had much less pain sense than when he was using morphine. Anesthesia extended from the stump up on the deltoid and across the shoulder from the center of

*Dr. Albert S. Taylor first suggested hemisection of the posterior roots instead of complete section of alternate roots. See Transactions of the Neurological Society, 1910.

the clavicle to the entire scapular region. This area showed striking irritability until the eighth day. If brushed over, it quickly suffused and remained so, but if pinched, it blanched and remained so for two minutes. This afterward disappeared.

Subsequent history.—For two years he abandoned morphine and gained twenty pounds. Four years later he complained again of pain in the stump and a drawing feeling in the amputated fingers. He was now seeking an increase in pension and renewed his morphine taking. Eight years later he still avers he has drawing pain in his amputated fingers and takes one and a half grains of morphine daily. The anesthesia remains the same. He obtained his pension increase and lived about the same till 1910, twenty-two years.

Case II.—G. Z., a man of 45. In 1886 he exposed his arm to a drafty car window while perspiring. In a few days had sharp pain between thumb and index finger, soon extending up the forearm and causing severe intermittent pain running into fingers. After two months he grew weak and nervously exhausted from the paroxysms of pain, which he also called "drawing pain." He acquired the habit of crying out aloud with each paroxysm of pain. Drs. Stimson, Flurher, and Gerster stretched and resected his ulnar and brachial plexus with aggravation, so that his attacks came every five minutes in the day and every half hour at night. His shouting with pain made him a dread nuisance to his neighbors. He grasped the arm and walked the floor in agony. Sleep was fragmentary. He required one-sixth grain of morphine every two hours to be even comfortable. September, 1889, I operated at St. Luke's Hospital and divided all the posterior roots of the brachial plexus within the dura, and resected a portion of each.

His pain abated slowly. In four weeks he was discharged with moderate improvement in pain, but taking no morphine. Two months later he had less pain, stopped crying out, and used no morphine. Anesthesia was complete below the deltoid insertion. His physician thought the amount of real suffering was now insignificant. A year later he was having a mild type of the same pain. Dr. Thacher's report of the resected nerve roots was: "Inflammatory exudation quite marked at portions of the surface and less marked at a few points inside some of the roots, the changes are most marked in and around the root of the first dorsal."

He became the inmate of a home, and some years later his physician said he had occasional paroxysms "which make him cry out, but unless some one is watching him he will play cards for hours at a time without sign of pain. He never requires anodynes, and what he still calls pain is a memory sense." He lived seventeen years. The arm was atrophied. The skin became hypersensitive and the fingers had a waxy glazed appearance. Autopsy showed marked arteriosclerosis. The left ulnar nerve showed a three-quarter inch tumefaction the size of a hazel nut and a second fusiform mass five-eighths of an inch long. The nerve was edematous and bound by adhesions These lesions may have been the sequel of early stretching.

Case III.—M. L. H., florist, age 40. Had partial infantile hemiplegia with athetoid paralysis of right arm and hand and partly of leg. Constant excessive athetoid movements of the arm and increasing neuralgia led to amputation of the forearm, stretching the brachial plexus and finally shoulder amputation by three prominent surgeons long before I saw him, yet his pain and incessant spasm drawing his shoulder stump high up on his neck continued. Neurologists continued to apply every form of electrical stimulation, without avail.

I was asked to stretch the cervical plexus, but instead, in June, 1894, I resected a quarter inch of the posterior roots intradurally of the 5th, 6th, 7th, 8th, and 1st dorsal (all that contributed to form the brachial plexus), and, on account of the persistent shoulder spasm, as his arm had gone, I also cut the anterior motor roots of the 7th and 8th cervical, which made the stump jump. At four weeks he was discharged with very great improvement. He still had a small amount of pain sense,

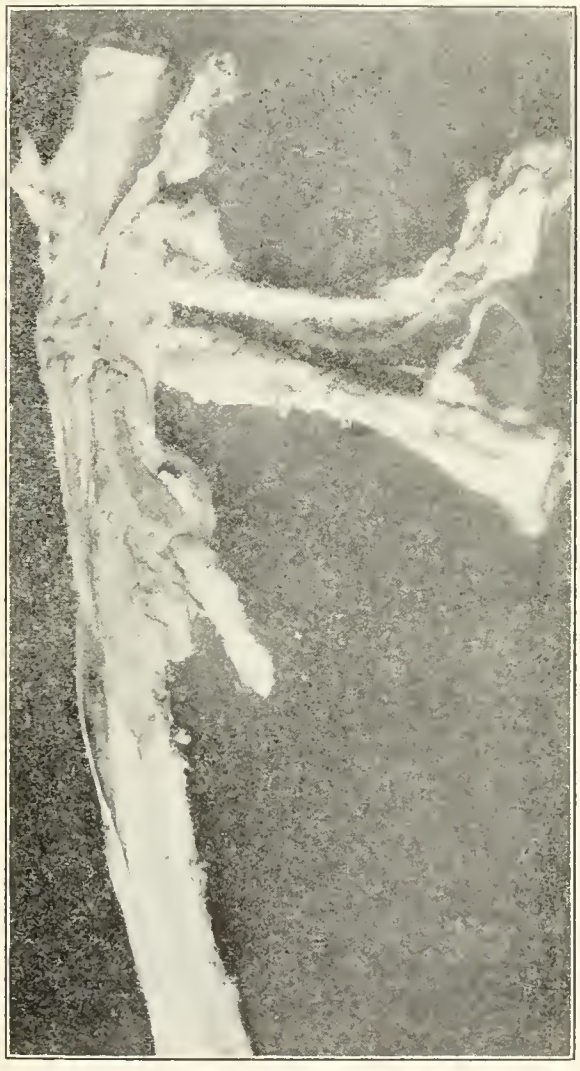

Fig. 2.—Case IV.

but the constant athetoid spasms had gone and the stump could be handled freely without being thrown into violent spasm. He could raise and lower his shoulder at will, which had been impossible before operation. For four years I watched him. He said he suffered, but the old athetoid spasms did not return. He died in 1910, and up to that time complained moderately and took his morphine.

Case IV.—A bookkeeper, aged 24 years. More than one year ago had shooting pains in his right forearm, which in six months extended to the upper arm, shoulder, and scapular. Numbness and tingling of the hands and fingers followed. A tumor developed and had been felt in the axilla six months later. Examination shows atrophied muscle

paralysis of entire arm and a large inoperable sarcoma of the axilla and sub and supraclavicular region. Pain was unbearable and required morphine. April 23, 1909, I divided the posterior roots of the 5th, 6th, 7th, 8th cervical, and the 1st dorsal with great care not to injure the anterior roots.

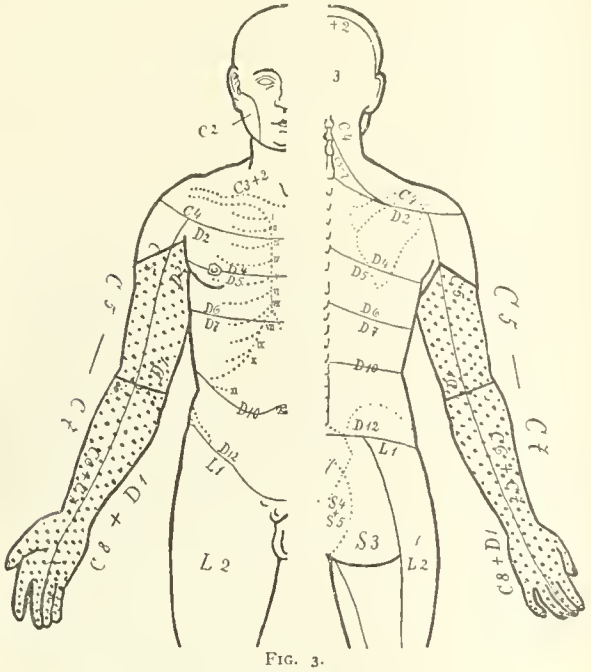

Fig. 3.

The patient had marked and immediate relief of pain. Anesthesia of the hand and arm up to the deltoid and axillary line was absolute (Fig. 3).

Examination by Dr. Bailey, one week after, finds total insensibility of the arm, involving joints as well as skin. Over the deltoid, sensation was blunted. On the side opposite the operated arm there was some hyperesthesia, and the hand opened and closed slowly. The right eye showed marked evidence of disturbance immediately after operation, which never afterward changed. The pupil was small and immovable, the palpebral fissure smaller, the eyeball a little sunken and a little flattening of face. The patient lived three months after operation and died of extension of the sarcoma in the neck. His pain sense was present, as it might well have been from cervical pressure, but he never lost the paralysis of motion and sensation in the arm which followed the root section. The case justifies fully this operation for relief of such unbearable pain. Autopsy showed extension of sarcoma into all the nerves of the cervical plexus and into the very roots I had cut (Fig. 2).

Case V.—Spastic hemiplegia of the left arm two years ago. Hemisection of the posterior roots of the 6th, 7th, and 8th cervical, cure of the spasm and pain. M. L., aged 39. Two years ago she went to bed well and was found unconscious for three hours in the morning. On returning to consciousness had complete left hemiplegia and aphasia, the latter lasted three days. The hemiplegia continued, but gradually recovered in the leg so that she now walks with a cane; the foot turns inward and drags. The arm has never recovered, but has been continually subject to spastic flexure and constant dull aching pain in arm and hand. The pain is complained of not only in the muscles, but joints. The leg has also moderate pains. The arm is paralyzed, except that she can abduct it slightly from the body at the shoulder (Fig. 4). The pectoral muscles are in spastic contraction. The biceps also hold the elbow a little flexed, but, above all, the wrist is sharply flexed by the spasm of forearm flexor group, and the fingers are drawn in upon the palm in varying degrees. Besides the disuse and the pain, she is annoyed by the difficulty in working a glove on the hand, which consumes about an hour. The pain alone justifies her in seeking relief.

Dr. Pearce Bailey referred her to me for operation. July 21, 1910, under ether, I denuded the left half lamina from the 5th cervical to the 2d dorsal and removed only one side, leaving the spines untouched. Opened the dura, picked up and divided three of the five strands composing each posterior root of the 6th and 7th, and two of the four strands of the 8th root. Closed the wound. Immediately following operation the spastic contractions ceased and the fingers could be extended.

During the first week I found her sitting up admiring her hand, spread out on the pillow, to her great delight; the fingers straight out and the wrist like the well hand for the first time in two years. The pain also rapidly disappeared. No gain in power of the hemiplegic arm was noted. January 2, 1911, seven months later, she writes me "thank you for the relief you have given me; the pains in my hand and arm are greatly relieved, also the tension (spastic). The action is no better and the arm hangs useless at the side."

Inasmuch as the paralysis had been absolute, except for the spastic contraction for two years, we can say that all has been gained that could be expected from the nerve root section; namely, relief of contraction and constant pain, especially the joint pains. The absence of complete anesthesia, due to hemisection of the roots, is a decided improvement and permits all the restoration of muscle possible in a paralytic, which would be vitiated by contracture of opposing ones.

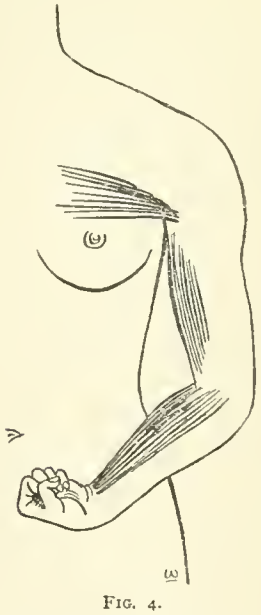

Fig. 4.

Case VI.—By the kindness of Dr. Lyle I am able to include a report of a case recently operated upon by him presenting features of interest.

A young engineer was violently injured by the lever of a heavy flywheel striking him in the right side of his neck at the level of the jaw in July,

1910. He was unconscious for twenty-four hours. The right arm was completely paralyzed and he suffered intense pain in the neck and arm. An exploratory incision showed that the roots of the cervical plexus were torn. The arm was then amputated. Six months later he was still suffering great pain. The right eye showed sympathetic paralysis of the eyelid, with contracted and undilatable pupil. In December, 1910, Dr. Lyle divided the 6th, 7th, 8th, and 1st dorsal posterior roots within the dura, using the unilateral lamina resection to expose the dura with ease.

The pain was at once completely relieved, but after three weeks pain has come, as if in his amputated thumb. The former pain had been more or less constant before operation, like a neuritis, preventing sleep. The arm had been amputated so that no notes regarding anesthesia are available.

Three matters of interest attract us in this new field. While the essential surgical features are supreme, there is always a measure of interest in ascribing due credit to the originator of the method. That there should be a tendency to call the operation by the name of a Breslau surgeon, Förster, is due to his very recent writing and advocating it (in spastic paralytics notably) in 1908. He and several recent writers seem to be unaware of the earliest known cases, those of Dana and myself and Bennett of London—which stood unique for awhile—though promptly published. Only the new feature of dividing a limited number of sensory roots is due to Förster. Among the best writings are Chipault and Demoulin, in 1895, in the *Gazette des Hôpitaux*, who review our first cases with Bennett's and credit Dr. Dana with prior conception; certainly the principle was first clearly enunciated by him.

Up to the era inaugurated by Förster, a dozen years after Dana, and my own reports—probably only fifteen cases given by Munro, seven by Chipault, one by Prince, and one by Chipault later, and one by Bennett, had existed. Even Munro, in 1904, had not included our cases of six years before. An admirable paper by Frazier and Spiller, in September, 1910, shows entire ignorance of the earlier work and credits Spiller with the earliest suggestions for this operation in 1905.

It is fair that an American name—Dr. Dana's—should be credited with the complete and earliest conception recorded of perfect comprehension of the possibilities and importance of the posterior root dural resection for pain. Following that and Dr. Bennett's resort to it (also for pain) the succeeding cases of my own were for pain plus athetosis. The extension of its use for spastic paraplegia may be credited to Förster, though my own third case was for pain in a hemiplegic with athetoid spasms.

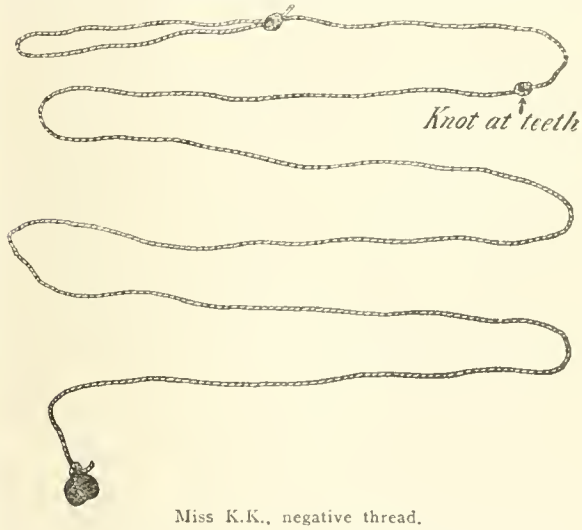
The further extension of the operation to attempted relief in cases of violent crises of pain and locomotor ataxia, and even in wryneck spasms, suggests a widening field not yet sufficiently tested for report. The principle of cutting the link in the sensory reflex chain is anatomically and physiologically correct. Although in paralytics the motor nerve trunks may not be able to restore function in all cases, the return pain-stimulus—which excites the spastic distortions seems uniformly to be relieved. The actual existence of neuritis in two of my cases was doubted by even such an authority as Dr. Seguin, who thought the pain probably delusional. In one, however, inflammation in the roots was demonstrated. When the patient persists in describing the spasm of pain as "drawing pains"; this has been so uniform a description without collusion that I have come to regard it as almost diagnostic of neuritis.

THE DIAGNOSIS OF AND THE FEEDING IN GASTRIC ULCER.*

By WILLIAM GERRY MORGAN, M.D.,
WASHINGTON, D. C.

My purpose in bringing this subject to your attention is not to discuss the classical symptoms as they are laid down in all the texts dealing with peptic ulcer, but to consider some of the newer methods which have been introduced, and to attempt to determine their true value.

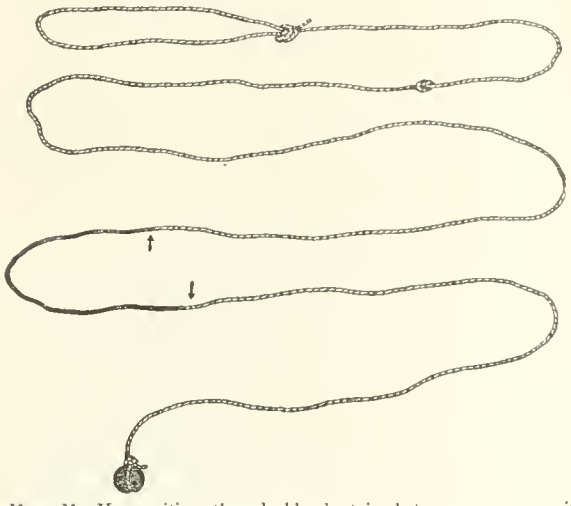
While it is true that in a large majority of cases of ulcer of the stomach and duodenum a diagnosis is easily made, it is just the minority which we should still be able to recognize. When we recall that statistics show that latent ulcers are discovered in from 5 to 15 per cent. of all autopsies, we must realize how many of such patients miss the benefits of a correct diagnosis and appropriate treatment. Without discussing further the routine methods in common use in examining patients presenting symptoms of stomach disorders, I will bring at once to your attention the method for recognizing and localizing gastric and duodenal ulcers, devised and presented to the profession by Dr. Einhorn in the early part of 1909.[1] This method consists in having the patient swallow, in the fasting state, a small metal bucket attached to a braided silk thread, preferably at night, and removing it on the following morning and examining it for a red or brown stain. The thread has a knot tied in it 75 cm. from the bucket, and the patient swallows it until this knot is just at the incisor teeth. The lower end of the thread should be yellow or greenish yellow, and the bucket should contain bile mixed with mucus, provided it has passed the pylorus, which it invariably does in from two to eight hours, provided there be no impediment such as a contracted pylorus or an extreme degree of dilatation due to atony. Should the bucket fail to pass into the duodenum, a smaller one is used the succeeding night, and in this manner an approximate idea of the size of the pylorus may be gained. By measuring the distance of the stain from the teeth we are able to definitely localize the ulcer.



Miss K.K., negative thread.

*Read before Clinicopathological Society, November 2, 1910.

In taking a new method, it is necessary to learn its limitations, so as not to be led too far afield. Therefore we may consider the possible sources of error with this thread test as follows: We may get a discoloration upon the thread in cases of advanced chronic gastritis, with softened boggy



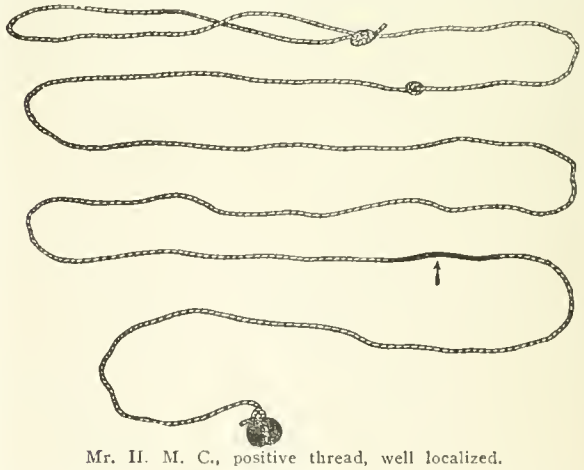
Mrs. M. H., positive thread, blood stain between arrows, with several small spots of clotted blood.

mucosa, in which there may be no ulceration, just from the dragging of the thread over such a diseased membrane; of this we are not as yet certain, but it is a possibility. In cancer of the esophagus, of the stomach, or duodenum we may get a stain upon the thread; also in hemorrhagic oozing due to cirrhosis of the liver or gastric erosion. However, in this latter condition the treatment is quite like that for ulcer, so that no harm would result in confusing these two. In those cases where considerable amounts of blood are swallowed as a result of some lesion of the mouth or upper air passages, a stain might appear, but these cases are rare, and in all probability would be easily recognized from their local symptoms. What has been said concerning lesions of the air passage is true of those others which I have enumerated, and to a careful clinician they will offer no serious obstacle to the usefulness of the Einhorn thread test.

For aid in recognizing and localizing ulcers in the fundus and greater curvature where the thread test is not applicable, Prof. Einhorn devised a thin, collapsible rubber bag of the shape and size of the normal stomach, over which was fitted a white muslin covering. A rubber tube connected with the rubber bag allows it to be inflated after it is introduced into the stomach, where it is allowed to remain a half hour, and deflated and withdrawn, and the muslin cover examined for a brown stain. This method is not easy to carry out and has a very limited sphere of usefulness.

To the twenty-three cases reported in my paper previously alluded to I could add over one hundred upon whom from one to four tests with the duodenal bucket have been made, which gives me a pretty definite knowledge of its value. From this experience I am prepared to maintain that if in any individual this test is made several times, and each time a stain is found at about the same distance from the teeth, you are then dealing with a localized lesion of the mucosa, which, excluding cancer, is probably ulcer.

So much for the Einhorn methods for the diagnosis of ulcers of the stomach and duodenum. Now let us consider for a few minutes the methods in vogue for feeding these individuals. In the early part of the last century, Cruveilhier, the pioneer in the study of gastric ulcer, was the first to advocate treatment of the condition by the rest cure and careful supervision of the diet. He looked upon the ulcer as he would upon one on the exterior of the body, and made the attempt to protect it and give it as much rest as possible. He declared milk to be the most ideal food, considering it to combine the two important features of being nourishing and at the same time bland and unirritating. But milk has certain disadvantages. There are cases in which milk cannot be given without its forming tough curds, thus necessitating the removal of milk from the diet, or a modification of the milk. Some advance was made when Reichmann discovered that boiled milk leaves the stomach more rapidly than raw milk, and that the curds formed are smaller and less firm. We now know that the administration of an exclusively milk diet for any length of time is slow starvation, that not all the materials, for instance, iron, needed in the economy are present in sufficient quantities, and that the patient will lose flesh and become more anemic. Attempts have been made from time to time, with more or less success, to overcome these deficiencies of milk by the addition of various substances, milk powder, 100 grams to 1000 c.c., condensed milk, etc. Cruveilhier's method stood as the standard until von Leube announced his method of treatment. His diet scale, consisting of foods graded according to their digestibility, and divided into four groups, was published in 1884 and is still one of the standard scales. The so-called Leube-Ziemssen rest cure has been the basis of practically all the medical treatment of gastric ulcer from the time it was first promulgated until Lenhartz, in January, 1904, came forward with his treatment, which was so radically different in its



Mr. H. M. C., positive thread, well localized.

first stages as to cause considerable hesitation before it was very widely adopted. One recommends abstinence from food for the first few days after a hemorrhage, while the other immediately gives concentrated proteid feeding. At this time the battle still rages between the two leaders and their followers. Von Leube's treatment is essentially as follows: (1) Absolute confinement in bed for two or three weeks; (2) hot flaxseed poultices in the day time and a Priessnitz pack over the epigastrium at night; (3) bismuth medication; (4) diet, which consists for the first week or ten days of milk, usually boiled, or milk diluted with barley water, oatmeal water, or rice water; Leube's meat solution, tea and a little bouillon, and toward the end of this period softened, unsweetened zwieback. If

hemorrhage has occurred recently, he gives no food by mouth, but depends on rectal feeding for several days, then starting in as above. Feeding is frequent and of small quantities, gradually increasing. For the next ten days he allows, in addition, boiled calves' brains, boiled thymus, well-cooked sago and rice in milk, gruels and mushes, raw and soft-boiled eggs. Later scraped beef is added, and in another week scraped raw ham and mashed potatoes, then gradually boiled chicken, venison, roast beef, pike, and the pureés. After the fifth week he gives careful ordinary eating, avoiding for some time coarse foods, skin, tendon, fruits, acids, alcohol, and spices. Leube has reduced his mortality from 13 per cent. in his first cases to 0.5 per cent. in his last series. He has reported[2] up to the present time 627 cases. In 547 cases without bleeding he had 90 per cent. of cures and no deaths, the average duration of treatment being four or five weeks. Of the 80 cases with hemorrhage, 90 per cent. also were cured and the mortality was 2.5 per cent. In his entire series of 627 cases he claims 90 per cent. as cured, 8.5 per cent. improved, 1 per cent. failed to improve, and 0.5 per cent. died. If the "abstinence cure" is attempted, for the first few days dependence is placed on rectal feeding. It is claimed that thereby the stomach is given complete rest and that a fair state of nutrition can be kept up for some days by rectal alimentation. Edsall and Miller have proven that saline enemata alone will keep up weight for some days, although there is an increase in the output of urea showing some destruction of body proteids. Less gastric juice is probably formed after saline enemata than after ordinary nutritive enemata. Metzger has shown that the addition of wine, as practised by some, increases the amount of gastric secretion. Michael,[3] in 1907, reported his investigations at Ewald's clinic regarding the relation of nutritive enemata to the secretion of gastric juice. He has found that the ordinary substances used in the rectal feeding do not lead to secretion of gastric juice, at least not for one-half hour to one hour afterward, and he, therefore, concludes that rectal feeding is not in any way harmful in gastric ulcer.

Lenhartz, however, claims that frequent nutritive enemata excite the gastrointestinal tract to peristaltic action, and may thus even induce renewed bleeding. Opinion is still divided as to whether or not rectal alimentation produces a flow of gastric juice, and, furthermore, also as to the efficiency of this method of feeding. A number of clinicians do employ the nutritive enema during the first few days following hemorrhage, and some claim that not only is sugar solution absorbed, but that even starch has been proved at times to pass the ileocecal valve and be removed from the stomach by lavage. But it seems pretty well proved by the experiments of Edsall and Miller in this country, Body and Robertson in England, and other observers that it is doubtful if more than a minute quantity of actual nourishment is absorbed. Dr. Herringham[4] of England, then, is against rectal feeding except by saline enemata, and Ewald,[5] who formerly used eggs beaten in milk, etc., now says that the nutrient enemata are mainly useful for supplying the body with liquid.

The results obtained by Prof. Leube with his technique have been approached by many men employing his methods, and in fact this technique, or slight modifications of it, is the most in vogue today. Lenhartz, however, is strongly opposed first to the primary "abstinence cure," and later to the feeding with as large an amount of milk as is used. He considers that the healing of an ulcer of the stomach is inhibited by (1) mechanical stretching of the stomach, overdistention; (2) hyperacidity, and (3) anemia. Milk he regards as insufficient, and claims that the anemia is aggravated thereby, and that furthermore an amount of milk large enough to give the patient sufficient caloric value will of necessity stretch the stomach. He affirms that patients on the abstinence cure lose weight and strength, that the blood pressure and pulse volume fall, and that he has not found acidity to be much lessened, later, when taking the milk. Lenhartz, therefore, recommends from the start, even in cases with hemorrhage, the administration of concentrated albuminous food, which will supply sufficient calories to the organism, and all the elements that the system needs, without distending the stomach thereby. This class of food also binds the hydrochloric acid physiologically and prevents its inhibiting the healing of the ulcer. He rapidly increases the amount of nourishment to repair loss of flesh and strength, thus improving the general health, creating favorable conditions for the cure of the ulcer.

He enjoins absolute rest in bed for four weeks, the use of the ice bag over the epigastrium to prevent distention, administration of bismuth, and the regulation of the diet according to the foregoing principles. He relies principally upon fresh eggs, chiefly raw or beaten up, and in increasing quantities. The first day, even when hemorrhage has just occurred, he allows one to three eggs, iced and given with a teaspoon; also 100 cc. of milk given the same way. He adds one egg a day until eight are taken, permitting them to be soft boiled after the first few days. Sugar is added the third or fourth day, and increased to 30 or 50 grams. He watches the progress with milk very carefully, and if well borne he increases 100 cc. a day until 1,000 cc. are given. He never exceeds this. From the sixth day onward 35 to 70 grams of raw scraped beef are added, and on the seventh day well-boiled rice. On the eighth day the patient receives softened zwieback or toast, cereals, 26 to 40 grams of butter, and finely divided raw ham on the tenth day. The diet list is then gradually increased according to conditions present. Lenhartz claims for his treatment (1) shorter duration of treatment; (2) pain is relieved by the diet alone in several days, no opiates being required; (3) vomiting ceases; (4) the number of recurrent hemorrhages is far less than with the other methods. In his first 201 cases only 13, or 6.4 per cent., had recurrent hemorrhages, while his last series of 106 cases was even better, with only four cases of recurrent bleeding; (5) quicker return to full strength and working capacity; (6) good effects are lasting.

Prof. Leube,[6] replying to Lenhartz, claims that while eggs, milk and sugar may bind the acid at the same time they cause the secretion of more acid and increase peristalsis. His examination of the blood in twenty-five cases on his liquid diet did not reveal any marked reduction of hemoglobin. While admitting that his patients lose weight at first, he says that they have more than made it up by the end of the second week. He thinks that Lenhartz's diet may be given without much danger except following hemorrhage, when he emphasizes the complete abstinence from food for some days. He is convinced from his thirty years' experience that the only way to insure the production of a thrombus in the bleeding vessel is to keep the stomach absolutely

at rest. Curiously enough, according to Lenhartz and the other observers who have been using his treatment, the best results have been obtained by the immediate feeding in just the class of cases in which Prof. Leube warns against its use, namely, in cases in which hematemesis had occurred shortly before. Lenhartz, in a paper read before a German Congress recently, reported 295 cases, in 262 of which there had been hemorrhage just before treatment was started, and in 33 of which blood was found in the stool at that time. His total mortality was but 2.3 per cent., and only 18 patients had recurrent hemorrhage after the treatment was begun. He commented particularly upon the speedy recovery with absence of weakness.

Wirsing[7] reports comparative trials with the Prof. Leube and Lenhartz methods. He obtained distinctly better results with the Lenhartz technique in cases of hemorrhage, finding that more nourishment could be taken and utilized, and that, although it irritated the ulcer somewhat more, the advantages offset the objections. He found, on the other hand, the Leube treatment to be much more successful in cases without hemorrhage and anemia. His total number of cases amounts to 320, in 42 of which he used the Lenhartz diet. One-half of this number had had recent hemorrhage. He found the acidity to approximate normal during the treatment, and the patients all gained in weight and strength. Hemorrhage did not occur in any case in which it was absent before. He finds that approximately 68 per cent. of his patients with hemorrhage are permanently cured, and 53 per cent. of the non-bleeding cases.

Lüdin[8] also compares the two systems of treatment. The Leube diet was employed formerly and the Lenhartz for the past two years at Gerhardt's clinic at Basle. There were fifty-five cases before 1907, and forty-five since. He found the percentage of cures to be about the same in the two series, as also the duration of treatment. He suggests that the Leube treatment is preferable in the subacute cases in which bleeding had already ceased before entering the clinic, but that the Lenhartz diet seemed to be better when the ulcer was still bleeding, although he allows three days of fasting after a hemorrhage before beginning the diet. In the cases with no history of hemorrhage the percentage of complete cures seemed greater under the Leube treatment, but the duration of treatment was longer than under the Lenhartz. His criterion for cure, namely, when the patient could tolerate a full diet and be able to spend several days out of bed without distress, is certainly inadequate when one considers the typically remittent course of a chronic ulcer.

Mayerle[9] reports his results in 71 cases treated by the Lenhartz method, 29 recently bleeding ulcers, 17 chronic, and 25 acute non-bleeding ulcers. He obtained a cure in a short time in 65 per cent.; a recovery in a longer time, but without recurrence, in 11 per cent., and with recurrence in 14 per cent. There was no benefit in 10 per cent. A few patients did not tolerate the diet very well, but he could detect no bad effect, even when the diet was commenced immediately after a hemorrhage. When the diet occasionally caused an increase in acidity, he diminished the proteid and increased the fat with good results. In the few chronic cases with reduced acidity he gave a diet with less proteid and fat and more carbohydrate. Ewald,[10] in 1908, in speaking of his last 166 ulcer cases, said that he had observed tardy hemorrhage in 4.8 per cent. He noted that this bleeding occurred when food was taken by mouth and vanished when the patient was nourished by rectum. In 1906 he reported 34 cases in which he used nutrient enemata for three days, followed by the Lenhartz diet. Fourteen deaths occurred during treatment or after subsequent operation. He condemns the Lenhartz treatment as unsatisfactory. Schmidt believes in the Lenhartz diet, but also gives the stomach a rest of a few days like Leube, and then increases the diet more rapidly, giving gelatin, eggs, butter, cream, sugar, and rice, using chopped beef and ham with great caution. Lambert was one of the first in this country to endorse the Lenhartz treatment. He is rather enthusiastic and concludes that the original claims of Lenhartz are correct, that the treatment is equally as efficient as the old method, that it does not deplete the patient, that the cure is more rapid and more certain, that the bleeding and vomiting stop more quickly and relapse less frequently, that the pain disappears promptly, that it is possible to treat the patient for his anemia sooner with iron, and that the return to free diet is earlier and easier. Obtaining these manifold advantages, one cannot blame the Lenhartz followers for being enthusiastic. Haberman[11] reported very favorably on the Lenhartz régime which is employed at the Eppendorfer Hospital, Hamburg. He presented 135 cases with only three deaths. Hemorrhage recurred in but 8 per cent. as compared to 20 per cent. in 100 cases treated by the old method. He says he has never seen any bad effects manifested even in hemorrhage cases. Spriggs[12] last year read a paper before the British Medical Association based on the results obtained in 33 cases treated by the Lenhartz method and 34 cases by the old method. He claims that the Lenhartz treatment is not more dangerous than that by saline enemata followed by gradually increased milk diet. In these particular cases recurrence of the hemorrhage was less frequent and there were no deaths. The rest of the advantages claimed by Spriggs are practically those originally put forward by Lenhartz. He mentions in addition the advantage of being able to do away entirely with rectal alimentation, which at home is unpleasant at best and rarely efficiently given. Spriggs quotes Berger as being so convinced of the efficiency of the Lenhartz method that he uses it for diagnosis. If the patient does not do well the disease is probably not ulcer. He cites six cases in which failure to improve on the diet led to the diagnosis of gastric cancer, which was confirmed in all at operation or autopsy. He also claims that in cases of epigastric pain without bleeding which do not yield to the Lenhartz diet nervous disease should be suspected. Wagner in 1904 reported 60 cases after Lenhartz's method, 35 of whom had no pain after the beginning of treatment. In only six did pain last after the first week. Heretofore in chronic ulcer cases which have not improved under a systematic rest cure with Leube's treatment, many have advised operation. Now, it would be wise to give the Lenhartz method a trial before operative measures are endorsed.

Although I have quoted the various workers as advocating a certain line of treatment, apparently in all cases, still we should not lose sight of the fact that each case is an individual and a law until himself. As Stockton[13] says, "in some cases feed the patient sufficiently but discreetly, in others depend for a period on salt solution enemas." There are

many factors to be considered in choosing the diet for the individual case, as the degree of anemia, loss of body weight, amount of acidity, presence or absence of hemorrhage, the condition of motility of the stomach, the patient's ability to carry out one or other line of treatment, etc. Senator[14] advocates a middle course and seeks to combine the advantages of both methods. He seeks to obtain a soothing diet to prevent recurrent hemorrhage, a food which will counteract the hyperacidity, and one which should be easily digested and nutritious and avoids an excessive amount or weight of food to stretch or weigh down the stomach. He allows, therefore, in addition to albumin, gelatin, fats, and sugar. The gelatin has the advantage of nutritive value partially replacing the proteids, is easily digested, and has the possibility of being a local hemostatic. Fat tends to diminish irritability and is, therefore, sedative and keeps down the acid. Sugar is similar in its action. He gives daily 15 to 20 grams of gelatin, ½ pint of cream, 30 grams of butter, which may be taken as frozen butter balls. Later milk and eggs and about a week after hemorrhage has stopped scraped beef. The cream is iced or beaten with sugar. Gelatin is stopped if there is constipation. Oil may be given instead of butter.

Nearly every clinician has one favorite food or modification of treatment in ulcer of the stomach, some of which may be mentioned in passing. Rosenheim approves of gelatin, using it in 5 to 8 per cent. solution in citric acid. He avoids meats, preferring a lacto-vegetable diet. Conheim gives 2 to 4 ounces of olive oil daily through a tube before breakfast or 1 to 2 ounces without the tube before each meal. This soothes and protects the ulcer, counteracts acidity, is nourishing, and allows food to pass out of the pylorus easier. Kemp uses a slightly modified Lenhartz diet and Einhorn a slightly modified Leube treatment. Fleiner recommends meat jelly made by boiling chicken or beef with calves' feet. Leube and Rosenthal give meat solution in many cases. Riegel orders 60 grams sugar (dextrose) in 20 per cent. solution per day, as experiments have proved it to diminish acidity. Fuetterer believes that resistance to healing is largely dependent on the diminution of hemoglobin and recommends a daily dietary of freshly expressed juice from five pounds of meat. Steinberg[15] believes that the chemicophysiological factor is a negligible one as compared to physicomechanical predigestion. He has devised a number of utensils which allow food to be ground and strained, yet retaining a consistency which favors mastication. The foods are smooth and make little demand on the motor functions of the stomach, being as he terms it "physically predigested." He recommends making tasty French dishes in this way, evidently disregarding increased stimulation of gastric juice thereby. This, then, represents the different methods of feeding, by mouth and per rectum, in gastric ulcer, the most of which are in more or less general use to-day.

Last spring Dr. Einhorn in seeking a practical method for securing the duodenal contents for clinical examination devised his duodenal bucket. Not being able to secure sufficient material for thorough examination, he went further and invented his duodenal aspirator which I show you here and by means of which considerable quantities of duodenal contents may be recovered at will. At once he conceived the idea that certain affections of the esophagus and stomach would be benefited by feeding through this duodenal tube directly into the gut, thereby giving the intervening portions of the alimentary tract an absolute rest. At the first opportunity he put a patient suffering with a chronic ulcer with spasmodic contraction of the pylorus upon this duodenal feeding with the most gratifying results. The patient gained rapidly from the very first and made a perfect recovery. Since that time he has been using this method in suitable cases, always with success. I am at the present time treating two patients by the duodenal method of feeding. The first case in Washington to be so treated was an officer in the U. S. A., who had been through a rather severe course of medical handling, having been subjected to several surgical procedures, and was more or less of an invalid. An ulcer of the stomach was diagnosed and the duodenal method of feeding suggested and readily agreed to inasmuch as all previous methods to recover good health had failed. Accordingly the patient swallowed the duodenal tube at 10 P. M. and on the following morning the feeding was begun. Following Dr. Einhorn's rule, 180 c.c. of milk, yolk of one egg, and 15 grains of lactose were heated to 99° and strained through a very fine mesh sieve and injected very slowly by means of a glass syringe, twenty minutes being consumed in the process of actually forcing in the food, and this was repeated every two hours. From the first feeding some nausea and distress were experienced, notwithstanding that the amount of the feedings was cut down to 90 c.c. Finally immediately after the sixth feeding the patient vomited the tube and a little later the food mixed with quantities of bright yellow bile. Now, I had previously suggested to Dr. Einhorn the advisability of more closely imitating the physiological processes by giving the feedings after the method of Murphy with salt solution, namely, by the drop method, but he said he had found his system quite sufficient for all of his cases thus far. When my patient had tried taking the food as Dr. Einhorn advised, and I may add that the nurse in charge of the case is one of the most skilled and was greatly interested in this experiment, and had failed, I decided to try my modification and to that end had the duodenal tube connected to a porcelain-lined pint irrigator and placed at such a height that it requires about an hour for the 300 c.c. of fluid to run through into the gut. We began with the 90 c.c., but by the end of the first day he was able to take the 300 c.c. with perfect comfort. However, each time an increase in the amount has been attempted he has experienced discomfort from distention of gas in the intestines, which leads me to believe that the 300 c.c. is all he is able to digest and absorb. In addition to the feeding, 500 c.c. of normal salt solution is given by the drop method, by the colon, which adds to the body fluids and also serves to keep the feces soluble and bowel actions regular. In addition to these special means, the usual routine toilet was carried out. The patient has not experienced any inconvenience from the continuous presence of the tube *in situ*, and in fact some of his feedings have taken place while he was sleeping and entirely without his knowledge. He looks and feels very well at the end of ten days of duodenal feeding.

My second case is that of a young woman who has a history stomach disorder dating back for eleven years and giving such a picture of the classical symptoms of ulcer of the stomach as to leave little doubt but that the diagnosis at that time was

correctly made of ulcer near the pylorus. She was placed first upon the Leube treatment, which was carried out faithfully under the care of a skillful physician and trained nurse for some weeks with apparently good results, and she gradually resumed her normal daily life and food. After an indefinite period of comparative freedom from symptoms she again began to have trouble with her digestion and sought the aid of Dr. Clark, who recognized at once the nature of ailment and sent her to bed and put her under the Lenhartz method of treatment. She improved and gradually resumed her daily life, but she never felt quite well and did not gain in weight as all ulcer cases do when a cure has been effected. Finally, some weeks ago her symptoms increased, and as there were decided evidences of renewed bleeding and some stagnation of the stomach contents noticed it was decided to have a gastroenterostomy performed. But before the date set for the operation I had occasion to consult Dr. Einhorn and mentioned this case to him and he so strongly advised giving the duodenal feeding a trial, and because the patient was not in a very good condition to withstand the shock of so serious an operation, we decided to put her upon the Einhorn method. This was instituted several days ago and the results were parallel to those in my previous case, so that my modification had to be adopted. With the exception that we found that her limit of tolerance as to quantity was 120 c.c. every two hours, no difficulty has been experienced since the drop method was begun and the patient is improving. To show that I do not consider duodenal feeding is applicable to every case I may say in closing that we at present have five other cases under the modified Von Leube treatment, among whom there is only one who may in the near future, if at all, have to resort to this new régime.

APPENDICITIS AND ITS MOVING PATHOLOGY.

By G. K. DICKINSON, M.D.,

JERSEY CITY, N. J.

The proper and most fruitful method of studying any medical problem is through its evolution. Until within a very recent time diseases were known only by their terminal pathology, breeding a type of physicians known as "morphologists." Happily, through the numerous observations of educated and skilled surgeons, we are now able to view disease from other points than those seen in the dead-house, and we have a pathology which is living and moving. No better ground for a study of this kind, no more entertaining and instructive chain of connecting lesions have we than in the study of chronic types of appendicitis, and he who desires to perfect himself in diagnosis and prognosis should avail himself of every opportunity to study the peculiar tendency of all diseases toward dissemination. The older pathology speaks of metastasis, which is an indefinite term of a mystical inference. Modern pathology accurately traces one lesion into another, by processes of morbid physiology, strained nerve tone, or latent bacterial irritation.

The history of medicine is altogether too largely the history of treatment. Too much attention has been given to the therapeutic side and much too little to causes. To progress in the medical art the practitioner should turn his mind more constantly to the cause, and, in looking for the origin of disease conditions, or, better speaking, disease processes, the many factors entering into the etiology should be comprehended before any type of treatment be instituted. The great advance that medicine has made within the last score of years has been rendered possible by marked increase in the plasticity of the medical mind. There are those of us who can recollect the fierce controversies not further back than the '80's, which were so long in being satisfactorily settled. Pasteur's researches disproving "spontaneous generation" excited the scientific world to its foundation. Lister's antiseptic treatment of wounds created an antagonism which even led to its being compared to homeopathy as an exclusive dogma. So with other great discoveries which have materially altered the attitude of the medical mind. So much better educated is the physician of to-day, so much more accustomed to think than to believe, that we now have given us from the laboratory and the clinic ideas just as revolutionary, yet which do not create a reactive animus, but are accepted as good working bases for investigations and practice.

Perhaps there is no truth recently evolved which has been so kindly accepted by the active practitioner as that we have no longer to deal entirely with terminal pathology, but with a pathological process and living pathology so beautifully demonstrated by the condition to be studied in this paper. A perfect understanding of living pathology and an accurate interpretation of its symptomatology are to be obtained only by a knowledge of all that exists in and pertains to the region affected.

On account of the very apparent discrepancy in the size of the appendix as compared to the cecum, the minds of anatomists have been so impressed as to give it a distinctive position and separate nomenclature. Embryologically, the cecum and the appendix are one. In fetal life it is but a funnel-shaped projection, yet a part of the cecum. Unlike most of the structures of the body, it has not finished its evolution, or, as some call it, its involution, at birth, but the same progresses as life extends. The reason for this may become more or less apparent as we study deeper into its genetics and physiology. We can truthfully maintain that the appendix is a cecum of the cecum. Its point of origin is constant and may be found about an inch from the ileocecal orifice. Wherever the ileum enters the cecum, an inch from that point will be found the origin of the appendix. The proper terminology for this portion of the anatomy is the ceco-appendix. It is a mesial organ, laterally rotated. To all intents and purposes the appendix and the cecum have a common vascular supply. They are affected by the same nerves

distributed from the same plexus. Histologically, we find the same coats common to both. The three longitudinal striæ of the cecum run down to its tip. The circular fibers also continue down, forming its greater mass. It contains in addition to the muscle layer considerable fine fibrous tissue. The inner circular muscle is about twice as thick as the external longitudinal. The proportion of muscle fibers varies with the individual, but in a normal person there is always sufficient to produce considerable contraction, as is evidenced to the surgeon on removing, when a four-inch appendix may be seen to contract one-half to three-fourths of an inch.

The most important point in its histology is the great accumulation of adenoid tissue. This tissue is found in abundance in three parts of the body: the tonsillar ring, the pyloric end of the stomach, and the ceco-appendix. It is found elsewhere disseminated. In these several areas there is a constant migration of phagocyting leucocytes into the lumen and back again into this tissue. They are most active in the walls of the ceco-appendix, which is an indication of a greater need for such activity. This lymphoid tissue obeys the same law throughout the body. As we have greater atrophic absorption of the tonsil mass in the throat as age progresses, so we see its gradual diappearance from the cecum and the appendix, though it may exist in abundance as late as the '70's. Although the appendix is morphologically a part of the cecum, its vascular supply comes directly from the region of the terminal portion of the ileum. Its mesentery is an extension of the mesentery of the last inch of the ileum. Frequently we also find the one non-vascular fold extending from the distal surface of the ileum at its junction with the cecum down onto the appendix, which is an important factor in some of the pathological sequences of ceco-appendicular lesions.

A morphological study of the appendix and cecum has been very thoroughly made by some of our comparative anatomists, and, as we said at the beginning, to comprehend disease conditions requires a knowledge of evolution of disease, so it is equally important to know the evolution of the organ diseased. Animals, we are told, vary materially in the length and morphology of their intestinal apparatus. There is a direct and important connection between the customary diet of an animal and the size and shape of its cecum. Animals living on a largely vegetable diet, containing a considerable quantity of undigestible food, require a more elaborate digestive structure in the upper portion (as, for example, the numerous stomachs of the herbivora), and an equally large surface for the absorption of the nutritive products of digestion in the cecal portion. On the other side, in the carnivorous animals, whose diet is restricted to food with little refuse, we find a small cecum or an absence of same. This wise provision of Nature, so thoroughly regulating the structure of the intestinal tract to the customary diet of the animal, is also affected by the metabolic demands of the individual. Some rodents, the wombat, anthropoid apes, and man live on a mixed diet, and they alone, and it is only in these few species that we have the peculiar type of cecum which the early anatomists first termed the cecum and its appendix, which is an erroneous nomenclature, however, for both are anatomically one organ. It is interesting to note that of these few animals which possess a narrowed type of cecum, man is the only one living an artificial life, having changed his dietary since civilization began, from raw food to cooked, from a monotonous diet to a most varied one, gormandizing far beyond his needs on foods and condiments of a liquid as well as a solid type, thereby traumatizing the entire intestinal tract from the stomach to the end of the large gut. There have been no cases of appendicitis discovered in the wombat, the rodent, or the anthropoid ape. In man alone, so far as dissections have shown, does this disease exist.

Among physiologists there is considerable dispute as to whether or not the appendix has any function. Certainly we have the right to believe, so far as present knowledge can point, that there is no distinctive function and that the economy can be conserved without its presence. The same can be said of an equal length of any part of the intestinal tract but every inch of the intestine has its part to do. There is an antiperistaltic wave in the large gut from about the middle of the transverse colon down toward the cecum, helping to maintain in that part the presence of digested but not completely absorbed nutritive fluids, and as the cecum is the buffer for contrapressure, contracting upward against the mass content of the large gut, and in this contraction steadying and tightening the ileocecal ring, it thereby inhibits regurgitation into the small gut. If the histoanatomy of an organ be an indication of its physiological function, then the excess of lymphoid tissue in the ceco-appendix should show its purpose.

Another physiological function, which it also possesses in common with the rest of the intestinal tract, is the secretion of mucus, Nature's lubricant of the tract, which, from its high tension, smears the epithelia and protects them from traumatism. If we may judge by analogy, searching into the comparative anatomy and physiology of other animals and the changes in our demands upon the gastrointestinal tract by marked alteration in our dietetics, we can perceive the reason why the ceco-appendix is in a condition of genetic instability. It is possibly attempting an evolution tending to the protection of an individual whose demands are excessive and unreasonable. No more do we confine our physiological thoughts and investigations to regions, but in studying the action of an organ consider its relations to other organs and the coordination of function or disturbance of function which may exist. The harmony of physiological interactivities is sometimes demonstrated only when morbid processes occur, in this region; a branch of the pneumogastric nerve runs down through the sympathetic to the cecum, as do also branches from the spinal system and numerous filaments from the sympathetic. We can but judge that this plentiful innervation must have some connection with the physiological demands of other organs thereby connected. This will be demonstrated more positively when we come to consider evolution of disease processes from a morbid physiology, through minor lesions to terminal ones of prominent import.

The continued antiperistaltic action of the large gut against the cecum, aided by the weight of a considerable quantity of fluid feces, with the contraaction of the cecum, tends (particularly if the mesentery of the cecum be lax or absent), as life progresses, to a ballooning out and pouching between the lateral striæ of its coats, inducing a ptosis of this viscera into the pelvis. These pouches are more pronounced on the outer side, the close contiguity of the orifice of the appendix and ileocecal valve remaining fairly constant. If the terminal part of the ileum be not firmly attached by its mesentery, the axis of the cecum is swung toward the middle line, but the

entrance of the ileum into the cecum is still direct and undisturbed. If the ileum remain firmly attached by its mesentery, and particularly if the non-vascular web running from its distal portion down onto the ceco-appendix be firm, the descensus of the pouch will produce traction on the ileum with more or less of a kink occurring. Constipation, incomplete, and even complete intestinal obstruction have been induced thereby.

Intermittent traction on the end of the ileum may [illegible] of nerve tonus in the ileo- regurgitation of fluid feces [illegible] the small intestine, and as the [illegible] prepared for the presence of same, not [illegible] cquired a natural immunity against the germs so commonly found in the large intestine, trouble ensues. An over-distended pouched cecum may contain as much as a pound of fluid acrid feces of most poisonous content. Owing to its distention and consequent paresis, there must be a residuum, which may be compared in a sense to a septic tank where there is an excess in the activity of the intestinal germs with putrefaction. It is not to be wondered at that in human beings with perverted appetites, with food that is seasoned and made attractive, and liquors and conversation to prolong meals, the intestine should be called upon far in excess of its ability to digest completely and that there should be poured into the large gut food not digested by the enzymes or bacteria of the upper tract, which undergoes fermentation and irritates to the extent of producing lesions in the ceco-appendix and lower part of the colon. In spite of the activities of the lymphoid tissue here present, a limit will be reached beyond which it is unable to respond with normal function. In comparing as above, we have here, as in the tonsillar ring and pyloric end of the stomach, an evolution from normal activity to exaggerated activity, then into a condition similar to minor inflammatory reaction. The lymphoid tissue becomes injected, its resisting power diminishes, phagocytes carry germs into its tissues, where they are not destroyed by the proper antibodies, and, the surface being traumatized, lead on to a superficial or so-called "catarrhal condition." When the cecum is inflamed, the appendix will be. But the cecum is open and drains. The appendix, whether with or without the valve, may become contracted either by the swelling of the valve or of the intestinal wall at the point where the appendix enters—a condition of croup. This occurring, it cannot drain; the catarrhal condition in the cecum will subside, that in the appendix to continue.

It seems from the work of the surgeon, as he operates on the milder cases, that "appendicitis," as we have known it from the time of Fitz, who first described it distinctly, is a misnomer, if we are able to think in true pathology. It should not be considered a strictly localized condition, but more properly the term "cecoappendicitis" should be used, as the probability is that all cases of appendicitis originate in a previous cecitis. At one time the opinion was held that ordinary changes in the arteries or thrombi of the smaller veins were responsible for this disease. We cannot hold to that at present. All types of appendicitis are primarily bacterial. The bacterial invasion comes through the mucosa, and, except in cases of volvulus or kinking from trauma, such should be considered its pathogeny, and its origin be sought for in the cecum. According to the number and type of pathogenic bacteria, the resisting power of the lymphoid tissue, and the ability to constantly drain itself, will be the extent and severity of the appendicular lesion, its duration and complications. Severe infection, mild resistance, croup, and extending lymphangitis may rapidly lead to a severe inflammatory reaction with possibly local or general gangrene, and, particularly if scybalæ or fluid feces be present, a perforation; but if the entrance to the appendix from the cecum be funicular, its mesentery extending to the tip, thus preventing volvulus, if the lymphoid tissue be abundant and possessing good physiological function, if the pathogenic germs are not virulent in excess of the protective powers of the mucosa, then we may have a condition analogous to and as safe as that discovered in the cecum proper, with restitution possible, complete, or incomplete.

Repeated minor attacks of cecoappendicitis may occur without any symptom recognizable to the individual. There may be absence of local pain or distress and no lymphangitis sufficient to disturb the economy, but if the life be unsanitary and the ceco-appendix traumatized continuously by an especially acrid, highly microbic fluid, then the catarrhal condition, or, to use a better term, the lymphangitis, may spread to the sub-mucosa, giving origin to a fibroid type of cecoappendicitis which is characterized by an excess of fibrous tissue in the wall of the cecum and appendix, particularly noticeable towards the tip. This continued inflammatory reaction of the lymphoid tissue and deposits of fibrous tissue in the sub-mucosa and muscular layers may lead to an absorption of some or all of the lymphoid tissue, with partial or complete obliteration of the lumen of the appendix and thickening and stiffening of the cecal wall. It has been claimed by physiologists that the appendix is an organ in retrogression. One of their arguments is its peculiar shape as compared with the cecum, associated with the fact that they are not able to explain its function. Neither had we been able to explain the function of the gall-bladder until within a few years. It, too, had been considered an organ in retrogression. Another argument brought up was the disappearance of lymphoid tissue, which surgical pathologists of to-day lay to repeated attacks of an inflammatory type. Sometimes with favorable conditions existing as to drainage of lumen and contractility of muscle, the lymphoid tissue will break down in one area, producing a septic ulcer that may fail to heal—a pathological process very analogous to the ulcers found in the pyloric end of the stomach, which are simply broken-down adenoid tissue. This septic ulcer may be the basis for absorption and transmigration of septic fluids and intestinal germs in continuous abundance.

Thus, we see, there are two types of the chronic and sub-chronic cecoappendicitis, the more chronic type leading to destruction of lymphoid tissue, and formation of fibroid tissue with the disappearance of the musculature. In the other we have some hyperplasia of lymphoid tissue formation of a septic ulcer, with but little change in the musculofibrous structure. From these two types we have a distinctly different moving pathology, and, of course, a various symptomatology, and in neither do we necessarily have at any time the local signs and symptoms which for years have been regarded as the signs and symptoms of appendicitis. The proper perspective of these two lesions could never have been obtained post-mortem, nor could ever have been obtained if our knowledge were to rest entirely on the observations of morphologists, but it has come to us through the repeated and careful investigations of the learned surgeon who in his operative work has not confined

his attention and collaboration merely to the organ to which the symptoms complained of seem to refer.

A fibroid appendix with a coexisting fibrosis of the cecal wall circumscribing adhesions inhibits the action of the latter in its efforts to sustain the column of liquid feces in the ascending colon, which becomes, through its functional instability, more pouched, more of a receptacle for the foul content, and more and more prone to hold a residuum, and, as it pouches, its direct traction on the ileocecal ring and its indirect traction on the ileum, through the thickening of the ileocecal fold, allow of a regurgitation, eventuating in a regional ileitis. The nerves in the contracting appendix, partly through an inflammation analogous to neuritis and partly through compression of their fibers, produce a reflex effect upon the intestinal tract, and as irritation of the nerves inducing pain will interfere with the peristaltic waves so will the compression of the nerve fibers in the appendix and traction on the splanchnics in the cecoappendicular region interfere with the peristaltic of the large gut and induce constipation. This pathological condition leads to the further production of end products of putrefaction and perverts intestinal absorption, so that the blood becomes surcharged with effete products and a condition of latent toxemia exists, sometimes called intestinal dyspepsia or autoinfection. The nipping of nerves and the traction on mesenteries frequently are prominent causes of epigastric distress. The stomach owes its protection from disease in large part to the fact that its functions, secretory and motile, are so quickly affected if any other organ be diseased or disabled. It has been well-termed the "mother" organ of the body, being the first to develop in the lowest forms of life as well as in embryo, and thus, phylogenetically, the strongest. Appetite means gastric juice. Cecoappendicitis irritation reflected up the pneumogastric inhibits the formation of this juice. Appetite ceases. If the individual obeys his instincts, he will not eat, or will eat guardedly. This will largely diminish the morbid physiology of the intestinal tract.

Continued irritation of the nerves in the cecoappendix will lead to a condition known as nervous dyspepsia: sense of discomfort in the epigastrium, sometimes slight nausea, never vomiting, gassy distention with eructations, a fickle appetite, sometimes disturbances after a careful meal, without any after a hearty one, sense of distress in the bowels, flatulence, toxemic headaches, mental annoyances, and lassitude. Stomach analyses will discover at times an excess of acid, at others, a deficiency, but, as a rule, the enzymes do not vary. This perversion of gastric functioning is associated with epigastric pain and tenderness, with the tender point in a mesial line midway between the umbilicus and ensiform. Sixty per cent. or more of the supposed dyspepsias are peripheral in origin and the larger proportion of peripheral conditions inciting pseudodyspepsia have their origin in appendicitis.

A septic ulcer in an appendix may reach a similar terminal pathology by a different process. Instead of reflex effects through the nervous system, we may through the blood have a steady shower of germs and toxins carried to the liver, which, in addition to the ordinary demands acting on it through the intestinal tract, tends to induce periods of hepatic inefficiency as to bacteriolysis and toxolysis, both constant and important functions of the liver. From this inhibition we have germs and toxins entering the bile current. The visciation of the bile in a stagnant bladder leads to cholecystitis and may in time lead to the formation of gallstones. The pouring of the toxic germ-laden bile into the duodenum is a sufficient cause for regional duodenitis with ulceration. Moynihan says that 80 per cent. of his duodenal ulcers are associated with some type of appendicitis. In the writer's own work he has found a larger per cent. of cases of cholecystitis associated with chronic appendicitis, generally of the septic ulcer type. Normal bile is a fluid of very low tension and will spread through the intestinal tract as an oil spreads on water. One of the physiological purposes of the bile is to maintain a proper activity of the intestinal epithelia. In conditions of cholecystitis, associated, perhaps, with choledochitis, we have an unusual outpouring of mucous from the racemose glands. This will increase the tension of the bile and inhibit its tendency to spread through the intestinal canal, rendering one more liable to the absorption of pathogenic products.

The effect of a chronic cecoappendicitis is sometimes shown in another type of pathology through fibrosis of the cecoappendix and adhesions which may form in the neighborhood, thereby inhibiting the action of the cecum and interfering with that of the ileocecal valve. Retention of fluid feces with their decomposition and the flowing of pus and highly pathogenic germs into the lumen of the cecum from the diseased appendix may lead to a colitis. A defective condition of the bile, as mentioned above, interferes with its descent into the large gut. The presence of free bile in the large gut tends to liquefy the mucus and allows it to mix very freely with the feces. Its absence leads to accumulation, and with the colitis induced we may have, particularly if there be reflex disturbances from the pelvis, a symptom complex known as membranous colitis or mucous colitis. The clinical symptoms of nervous dyspepsia are never the symptoms so characteristic of any type of gastritis or ulcer. In differential diagnosis between organic disease of the stomach and functional disturbances due to extraneous causes, physical examination is generally of considerable value. Perhaps no one sign is more helpful in the determination of the existence of chronic appendicitis than the presence of tenderness at Morris' point. We seldom find the sympathetic plexus a little below and to the right of the umbilicus tender on pressure in an acute appendicitis unless the acute process be supplanted on top of a chronic one. Most of our cases of acute appendicitis are, however, secondary to chronic. Tenderness on pressure at Monroe's point, alongside the rectus, which is over the ileocecal valve, exists in a fair proportion of the cases, but there is rarely any at McBurney's point. If the disease has lasted long enough to show its effect upon the colon, tenderness on palpation along its course may be elicited. If the pathological process has worked through the blood stream to the bile current and gall-bladder and ducts, we may find a tender spot in that region. Almost invariably we have another point of tenderness in the mesial line above the umbilicus over the solar plexus.

Résumé.—The lessons to be learned from a study of this subject are: First, that the body, being an harmonious arrangement of organs, the functions in one cannot be disturbed without others being affected, for it may be set down as a law that an organ physiologically or anatomically associated with another will, when diseased, lead to some perversion of function or structure in the other; such is their genetic relation.

Second, that an appendix apparently healthy when examined macroscopically may prove to be badly diseased when examined microscopically.

Third, that the appendix and cecum are one and have a common inflammation.

Fourth, owing to peculiarities of structure the cecal portion may recover, the appendicular portion continuing the inflammatory process in a chronic type.

Fifth, according as is the nerve tone so will one type of appendicitis affect the large intestine or the gastric region, or both; or, as is the functional ability of the liver maintained or inhibited, so will the excess of germs and toxins affect the bile ducts and upper duodenum.

Lastly, stomach symptoms do not necessarily mean a diseased stomach. They are more apt to mean peripheral lesion, and it is wise for a diagnostician to suspect appendicitis as a causative factor.

VACCINATION IN THE PHILIPPINE ISLANDS.

By ROBERT OLESEN,

MANILA, P. I.

ASSISTANT SURGEON, U. S. PUBLIC HEALTH AND MARINE HOSPITAL SERVICE.

The enthusiastic Americans who are contributing to the success of the United States' greatest colonization project have become accustomed to the reiterated sentiments of the anti-imperialists, the anti-expansionists, the maligners of the climatic environment and resources, and the detractors of the governmental policy. They have become inured even to the misconceptions of the general sanitary status, but are not prepared to agree with the antivaccinationists in the home land that smallpox is unduly prevalent or that vaccination has proven a signal failure in the Philippine Islands.

Smallpox does exist in the Philippines, sometimes to such an extent as to occasion uneasiness among the inhabitants of certain unfortunately situated communities. More often, especially in the larger cities, the sporadic occurrence of variola excites no more concern than a passing rain shower. The persons who escape vaccination, either intentionally or otherwise, are those who contract the disease. Conversely, those who submit to protective inoculation remain free frm the affection, even though they come in actual contact with it. With so effective a weapon, it would seem a comparatively simple matter, requiring but a short space of time, to eradicate smallpox from the islands. But the remedy must be applied to every unprotected person now residing in the archipelago, as well as those who may come in the future.

Are there conditions, susceptible of proof and demonstration, which interfere with the successful vaccination of all the inhabitants of the Philippine Islands? The subject was deemed sufficiently interesting and important to seek the expert estimates of the district health officers, who are directly responsible for the sanitary administration of the islands. Therefore, circular letters were addressed to these officials, who, by their constant participation in extensive vaccinating campaigns and their intimate relation to patents suffering from smallpox, are peculiarly qualified to discuss the subject. A word as to the motives actuating their replies may not be amiss. The only interest these physicians could have in vaccination is in its ability to prevent smallpox. It is unreasonable to presume that after years of wearisome application and close observation of the results of inoculation, they would express unanimous approbation of a thoroughly worthless procedure.

The insinuation of the antivaccinationists that the medical profession advocates the use of vaccines and serums in order that private firms in which it is interested may profit cannot be applied in the Philippines. Here all virus is prepared by experts of the Bureau of Science, under the auspices and strict supervision of the Insular Government. The lymph is supplied to the district health officers in abundant quantities, and vaccinations are performed gratuitously, thus affording no opportunity for a financial interest either in the preparation or application of the product. It may be assumed, then, that the comments of these men are simply convictions emanating from experience and observation, untrammeled by prejudice, precedent, or the dictates of superiors.

The questions propounded for their consideration were as follows: 1. To what extent is recent successful vaccination a protection against smallpox? 2. How often do you consider it necessary to revaccinate in order to maintain immunity? 3. In your experience, were there any deaths, diseases, or serious infections that could, in any way, be attributed to inoculation? 4. Have you noted any deaths from smallpox in persons who have been successfully vaccinated? 5. What is the general attitude of the people in your district toward vaccination? 6. How do you account for the reappearance of smallpox in a community after vaccination has been completed? 7. Granting that vaccination protects against smallpox, what are the chief difficulties in the way of eradicating the disease from the islands? 8. Please detail specific instances, giving statistics, in which smallpox has either diminished or increased after a community has been thoroughly vaccinated.

The replies, coming from American and Filipino

physicians of wide experience and reputation, were enlightening and indicated unqualified approval of protective inoculation.

Recent Successful Vaccination.—By a successful vaccination is meant the local reaction, accompanied by manifest constitutional symptoms, which occurs after the virus of cowpox has been placed upon a surgically clean, scarified skin surface, and is marked by the successive appearance of a papule, vesicle, and pustule within a definite period of time. "The scar following such a reaction is distinguished by the presence of one or more distinct pits, closely resembling the pock-marks of a person who has recovered from smallpox."[1] A large, elevated cicatrix, radiated or smooth, but without pits, and accompanied by a history of suffering with an enormous, boggy, swollen arm, may be taken as an indication of a serious infection. It is extremely doubtful whether immunity is afforded in these cases. The term "recent" is used in this connection to show that less than one year has elapsed since the inoculation.

The consensus of opinion of the insular physicians clearly indicates that recent successful vaccination is an absolute protection against smallpox. The issue is not materially altered by a few who modify their answers by the expressions, "practically an absolute protection," "confers practically complete immunity," "99 per cent. are protected," "5 per cent. are not protected." An American physician, who has had a most extensive experience in the care and treatment of smallpox patients, makes the reassuring statement that "no successfully vaccinated person need fear contact with the most malignant cases of smallpox."[2] This should be a source of considerable comfort to sojourners in the tropics.

The Necessity for Revaccination.—There is abundant reason for believing that a person who has been successfully vaccinated is absolutely protected against smallpox during a period varying from six to twelve months, probably the latter. After this time his immunity may or may not continue indefinitely. It is probable that the constant efforts required in repelling invasions of the omnipresent contagium either weaken or partially destroy the protective forces, thus permitting the mastery of the disease process. The period of immunity is longer in an inoculated native than in an American or European. Years of constant exposure to the disease appear to have conferred upon the native a certain amount of natural immunity. This, reinforced by artificial immunization, affords the Filipino protection through a period exceeding that of the fair skinned races.

In the absence of means of determining accurately the length of perfect resistance it is best to revaccinate once a year, devoting particular attention to Caucasians. This rule is followed among the employees and permanent patients of the San Lazaro Hospitals in Manila, the absence of smallpox, especially among those who care for persons suffering from the disease, demonstrating the wisdom of the procedure. The otherwise perfect record is marred by the fact that an American nurse contracted smallpox while on duty in the contagious wards of the hospital. Upon close interrogation she admitted having intentionally nullified her vaccination by washing off the virus with alcohol. An unsuccessful revaccination may be variously interpreted. While it usually indicates the maintenance of immunity, it is also possible that the lymph may have been inactive, or the operative technique faulty. Therefore, too great reliance should not be placed upon a negative revaccination. That success often follows repeated efforts is within the knowledge of all observers and emphasizes the necessity for care in performing the operation.

Complications of Vaccination.—Much of the disrepute into which vaccination has fallen is due to gross carelessness, occasionally on the part of the inoculator, but more often on the side of the patient. Conscientiously performed and properly safeguarded, vaccination is accompanied by no inconvenience and is followed by no deleterious results. In the Philippines unremitting efforts are made to perform the operations under aspetic precautions. Vaccinators are persistently admonished to use alcohol and cotton liberally and thoroughly in the preparation of the inoculative site. In addition the scarifying instruments must be flamed before and after each vaccination. Regarding an effective protection for the completed inoculation it has been found that the loose sleeve of a clean, white undergarment forms an adequate covering. In this way the irritation and discomfort caused by the formation of heat and perspiration beneath a closely applied protective dressing is avoided. The method has the additional advantages of being economical and time saving.

The antivaccinationists have alleged rather persistently that vaccine virus is frequently contaminated with the causative agents of tetanus, erysipelas, syphilis, tuberculosis, etc., and that these diseases appear in many persons as a result of inoculation. In this connection the testimony of the District Health Officers of the Philippines is extremely interesting. An American physician, who has personally supervised the performance of 1,006,759 vaccinations in the islands, states that he has never seen even a "bad" arm.[3] He ascribes his success to a careful adherence to the rules of surgical cleanliness. Even the laity, which is invariably prompt in reporting the shortcomings of public officials, has failed to record a single untoward result of vaccination. Not one of the health officers has knowledge of a disease or death which could, in any way, be attributed to vaccination. Several, however, have encountered severe infections, which, considering the methods employed by the natives in preventing "takes," is not surprising. Ordinarily the virus is simply wiped off with a dirty hand or a filthy garment, but occasionally more elaborate means are used and vinegar, lemon juice, saliva, or tobacco juice are surreptitiously applied to the scarified spot. In some localities the people rub the leaves of certain plants over the inoculative site.

Vaccination as Life Insurance.—In the experience of the physicians of the Bureau of Health no person who has once been successfully vaccinated has succumbed to smallpox. The smallpox patients of Manila and the neighboring towns are isolated and treated in a division of the San Lazaro Contagious Hospitals. The superintendent of the institution, after years of careful observation, concurs in the emphatically negative statement of the other practitioners in the islands as to the absence of deaths among persons who have, at some period of their lives, been successfully vaccinated. In those rare instances in which persons who have been vaccinated contract smallpox the course of the disease is decisively modified and death never occurs.

Attitude of the People Toward Vaccination.—

While the people are coming to regard vaccination as a highly necessary procedure and each succeeding year records a gratifying increase in the number of voluntary requests for the measure, there still exists some opposition. The antagonism to protective inoculation arises from ignorance and superstition. "In one town (in Cebu) the belief prevailed that the virus was poison and would certainly kill. Upon investigation it was discovered that this opinion was held because of the use of lymph from amber colored glass tubes, while previously clear glass had been employed."[4] Much of the opposition is engendered through the invidious statement of the native antivaccinationists, who represent the Americans as desirous of exterminating the Filipino race by introducing poison into the bodies of the people. It is also "alleged that vaccination produces harmful effects during menstruation, lactation, and infancy."[5]

Because of the constant and determined opposition, the Bureau of Health was compelled to withdraw the vaccinators from the Province of Antique, in January, 1910. Subsequently smallpox increased enormously. In analyzing the situation, the more philosophically inclined of the people were struck with the fact that the disease prevailed exclusively among the unvaccinated. Those who had been inoculated, even prior to the American occupation, seemed to mingle with the afflicted with impunity. Having verified these astounding circumstances by careful investigation, the people began to besiege the Bureau of Health with cablegrams, letters, and personal representations, imploring that vaccination be renewed and promising unreserved cooperation. Thereupon, the vaccinators resumed their work and obtained the usual satisfactory results. When natives toil "over many miles of what might be considered impassable trails,"[3] when members of the Wild Tribes, especially the Igorrotes, "voluntarily present their children,"[6] when "every person in a town will assemble at the vaccinator's call,"[7] all for the express purpose of being vaccinated, there must exist evidence of real and proven worth. Certainly there is no healthier indication of mental progress among the people.

Relation of the Birth-rate to the Prevalence of Smallpox.—The vital link which the antivaccinationists have omitted from the chain of statistical evidence is the birth-rate. More than a quarter of a million births are recorded in the Philippine Islands annually. Were it possible to inoculate these children shortly after birth one of the most aggravating causes for the continuance of smallpox would be eliminated. But the native officials rarely can be impressed with the importance of vaccinating babies. Even though a community has been thoroughly and efficiently treated, the ever present contagium finds a fertile field for its activity among the unprotected infants. This contention is supported by the well known fact that epidemics are invariably initiated by cases among infants and that the vast majority of deaths occur in children. The recent recrudescence of smallpox in Cebu reveals the fact that "over 90 per cent. of all the cases were among unvaccinated children, that no cases were reported among persons recently vaccinated, and that the small percentage of adults attacked were nearly all unvaccinated."[8]

Obstacles to the Eradication of Smallpox from the Philippines.—Without a knowledge of the inhabitants and topography of the Philippine Islands it is difficult to appreciate the nature of the trials which beset the vaccinators. It may be readily realized that infinite patience and tact are required in dealing with a population composed of Christians, Mohammedans, and pagans, possessing eighty-four different tribal names and speaking thirty-seven distinct dialects. Just as water transportation in a typhoon-swept archipelago consisting of 3,140 islands, islets, and charted rocks is a problem demanding expert consideration, just so is the question of overland travel in a mountainous country with a total area exceeding that of the States of New York, New Jersey, Pennsylvania, and Delaware. "Hiking" long distances over rough trails, often delayed or isolated by swollen streams during the rainy season, the task of the vaccinator is one calling for courage and endurance.

Chief among the handicaps attending vaccination is the difficulty of preserving virus in the tropics. While the inoculative material is invariably fresh and potent when shipped from Manila, its condition upon arrival at the field of vaccination is often questionable. This is due primarily to the impossibility of icing the product during transit. The absence of refrigerating plants on practically all the interisland vessels and at the ports of call, the time required in completing voyages, and the difficulties of land transportation all combine in impairing the power of the lymph. It frequently happens that virus has been off ice sufficiently long to render it innoxious before it reaches the vaccinators. Moreover it is seemingly impossible to impress upon many of those charged with its care the necessity for haste in its transfer.

Approximately 9,000,000 vaccinations and revaccinations have been performed in the islands since 1898. Of these 60 per cent. have resulted positively. Worthless lymph, negative revaccinations, and deliberate attempts at nullifying inoculations are responsible for the 40 per cent. of failures. Taking into consideration the percentage of failures and also the fact that many of the recorded operations were repeated vaccinations in the same persons, it appears that considerably less than 5,000,000 of the population, ranging between 7,000,000 and 8,000,000, have been successfully vaccinated. The impossibility of maintaining constant and individual supervision over the vaccinators, who are necessarily natives, has permitted the employment of some dishonest Filipinos and has reflected upon the merits of vaccination. Records of vaccination have frequently been fabricated, fees demanded for services which should have been given gratuitously, and barrios (towns) reported as thoroughly vaccinated when such was not the case. So seemingly trivial a circumstance as the time of placing the virus upon the inoculative site really measures a difference of 20 per cent. of "takes." Therefore, the vaccinators must be instructed to place the lymph upon the cleansed skin before scarifying, a better opportunity for proper action being thus afforded.

Unless particularly cautioned, the vaccinator is apt to make the operation of vaccination a barbarous one, drawing sufficient blood to frighten the patient and either disastrously dilute or wash away the inoculative material. When it is impossible to evade the vaccinating party by staying within doors, the natives will hide in swamps, forests, or escape to the mountains, often absenting themselves for days. In one locality it was learned that the infants were being hid in trunks and boxes until after

the departure of the party. Many people, while submitting to vaccination with apparent willingness, will immediately afterwards institute steps to prevent the desired reaction. After systematic vaccination has been completed it remains with the local sanitary officials to maintain the advantage. But, unfortunately, the average native officer regards the practice of vaccinating the babies, the unprotected transients, and the periodical revaccination of all the people after the insular vaccinators have retired from the field as unnecessary precautions.

The Results of Vaccination in the Philippine Islands.—A gentleman who resided in Manila just prior to the American occupation has this to say of smallpox: "Some weeks ago there were even four hundred deaths a week from this disease alone, and from the way in which the afflicted mix with the hale and hearty, you can only wonder that there were not four thousand." With the advent of the Americans and their policy of persistent vaccination, a startling reduction in the number of cases and deaths from smallpox became apparent. Only once (in 1908) in the past ten years has the annual number of deaths in Manila from this disease exceeded 30. During 1905-6-7 there were but 8 deaths. In 1908, following a two years' suspension of vaccination, there was a sharp epidemic, in which a number of ardent antivaccionationists paid the penalty of their belief with their lives. No death from smallpox has occurred in Manila since June 15, 1909. The opponents of the measure assert that advances in sanitary science are responsible for the decrease of variola rather than vaccination. As Manila is noted for the magnificence of its sanitary achievements, this specious contention may be granted for the sake of argument and the attention directed to the results obtained in other localities.

During July, 1909, there were 21 deaths from smallpox in the City of Iloilo, which ranks next in importance to Manila. At that time the sanitary administration was notoriously lax. Representations to the provincial authorities that human life was being unnecessarily sacrificed resulted in an active campaign of vaccination. During August, when the work began, 12 deaths were reported; during September 8, and in October 1. Since that time there has been but one case of varioloid in the entire city and the new District Health Officer is able to direct his attention to some of the much needed sanitary improvements.

Systematic vaccination was begun in the Province of Ambos Camarines in September, 1906. The result was as follows:

3rd Quarter, 1906, 280 deaths.
4th Quarter, 1906, 80 deaths.
1st Quarter, 1907, 8 deaths.
Later to date, no deaths.

In this province four vaccinators are constantly employed in inoculating the infants and transients, thus reducing to a minimum the opportunity for the reappearance of smallpox.[3]

In 1904 and 1905 there were 446 deaths from smallpox in Pampanga Province. In 1906 vaccination was begun with some degree of regularity and was followed by exceedingly happy results:[10]

Year 1906, 35 deaths.
1907, 14 deaths.
1908, no deaths.
1909, no deaths.

The experience with vaccination in the Island of Cebu, which is the most densely populated section in the archipelago, is extremely interesting. Prior to 1905 there was an annual death rate from smallpox of between 3,000 and 4,000. Following the wholesale vaccination of 1905-1906 there was a reduction in the mortality to 94 deaths in 1907 and 84 deaths in 1908. Unfortunately vaccination was suspended during 1907 and 1908. In 1909 there was an increase in the mortality to 736.[8] As a result of this recrudescence the unprotected children were vaccinated and a large portion of the general population revaccinated. The officials who are conversant with the local conditions venture the opinion that the mortality from smallpox during the present year will be the lowest yet recorded. "In the provinces near Manila, which represent a population of about a million, there have been 6,000 or more deaths from smallpox annually. Last calendar year (1907) after such (systematic vaccination) was completed, not one death occurred from smallpox."[11] In 1908 the sanitary authorities in Pangasinan Province were confronted by a smallpox epidemic of alarming proportions and frightful destructive propensities. A vaccinating party composed of sixty men, under the supervision of three experienced physicians, promptly invaded the affected territory. At first the campaign was severely handicapped by the difficulty of obtaining fresh virus. Coincidently, cholera appeared and attention was necessarily directed to combating this scourge. In October, following the receipt of plentiful supplies of potent lymph, the percentage of successful vaccinations rose from 25 to 70 and even as high as 90 per cent. The expected diminution in the prevalence and intensity of smallpox was noticeable at once:[12]

Trimester.	*Year.*	*Cases.*	*Deaths.*
First	1908	4,080	2,282
Second	"	2,136	1,350
Third	"	501	326
Fourth	"	218	132
First	1909	267	123
Second	"	254	99
Third	"	108	48
Fourth	"	7	3

The Bureau of Health possesses additional authenticated records which demonstrate that systematic vaccination has been accompanied by astounding decreases and actual suppressions of smallpox. While sanitary improvements have been initiated throughout the islands, in no locality except in the City of Manila have they attained that perfection of development that would account for the elimination of an epidemic, contagious, and so virulent a disease as smallpox. The recent successful vaccination of all the inhabitants of the Philippine Islands will eradicate variola. At present, certain conditions, which have already been enumerated, delay the complete application throughout the archipelago of this most effective remedy. The communities in which these adverse conditions prevail contribute largely to the smallpox statistics and constitute the basis for the faulty conclusions of the antivaccinationist. Ocular proof of the beneficial workings of vaccination is within the reach of every resident and visitor in the islands. One has but to notice the extreme rarity of pockmarked faces among the children as compared with the numerous disfigured countenances of those who contracted the disease prior to or during the first few years of the American occupation to realize the remarkable changes wrought by this simple precautionary measure. One cannot but be im-

pressed with the prodigious discrepancy between an insignificant scar on the arm as contrasted with death, suffering, and permanent disfigurement.

I have to acknowledge my indebtedness to District Health Officers W. K. Beatty, G. I. Cullen, A. P. Goff, J. R. Hurley, Zach Laughlin, T. E. Moss, Arlington Pond, J. E. Snodgrass, T. W. Vincent, Luis Caballero, Andres Catanjal, Telesforo Ejercito, Arturo Garcia, Donato Montinola, B. Toribio, Rafael Villafranca, and Francisco Xavier for much enlightenment and valuable information upon the subject of vaccination in the Philippines.

BILATERAL NEPHROLITHIASIS; LEFT NEPHROLITHOTOMY.*

By L. BOLTON BANGS, M.D.,

NEW YORK.

The patient is a male 44 years of age, of exemplary habits, never having used tobacco nor alcohol. Since his seventeenth year he had had attacks of what he called "irritation" of his urinary organs, compelling him to urinate frequently and causing with each act a stinging sensation at the head of the penis. With the exception of occasional intermissions of a few months at a time, these attacks have persisted up to the present. At 29 years of age he had the first real attack of renal colic. This was on the left side, the duration of the attack being thirty-six hours, when he voided with the urine a small calculus. There was no vomiting nor any perceptible blood in the urine at that time. Four years later he had a similar attack in the left side and again a stone was found. In December, 1908, he had a similar attack, but this time it was on the right side. No stone was found in the urine; he was ill for several days and confined to his home for three or four weeks with fever, soreness in the right side of the body, and general disability. After this attack he did not fully regain his health for three or four months. For a period of about ten years he had, at times, found in his urine white granular material. In the latter part of 1909 he had, at intervals, a slight, dull pain in the region of the kidneys, more noticeable on the right side. This was considered to be "neuralgic," and he paid no attention to it. In January, 1910, at the end of an act of urination, vesical tenesmus took place, which forced out a small quantity of pus stained with blood. During the first half of 1910 he had attacks of fever, with a temperature rising to 100° or 101° F. During the latter part of the year, although there was no rise of temperature, he had a quick pulse and was not equal to the demands of his business, becoming easily tired and experiencing pain in the back on being jolted when riding in a motor boat or in the cars, or even when walking. At no time has there been any free blood in his urine.

*Reported at a meeting of the Practitioners' Society of New York, January 6, 1911.

The urine voided at his first visit was loaded

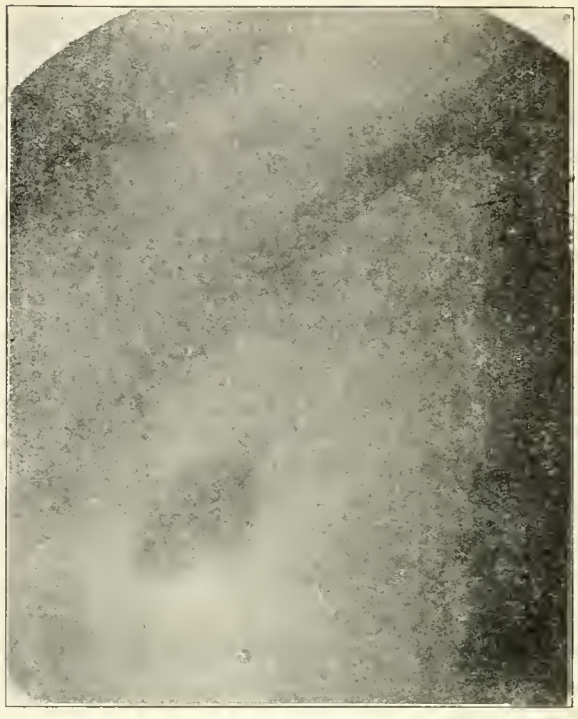

Fig. 1.—Right Kidney.

with mucopurulent shreds, had a mawkish odor, and its examination showed the following: Color, amber; sp. gr., 10/20 acid; trace of albumin; mucus, moderate large amount; red blood cells, small amount; no casts; epithelia, a few pavement and

Fig. 2.—Left Kidney.

cuboid; crystals, a few calcium oxalate. The patient is large and corpulent, weighing 210 pounds, and it was impossible to palpate his kidneys. The radiographs, which were made by Dr. Cole,

show a stone in each kidney. The left kidney is somewhat enlarged, the stone occupying a large area in the tissue of the organ. Subsequently the ureters were catheterized, and the urine was drawn from each kidney with the following findings: Right Kidney.—Color, red; odor, not offensive; sp. gr., 1019, acid; albumin, present ¼ per mille; urea, 1.92 per cent.; blood, small amount; pus, large amount; casts, few hyaline; bacteria, slight bacteriuria; epithelia, numerous, probably from renal pelvis. Left Kidney.—Color, amber; odor, not offensive; sp. gr. 1010, acid; albumin, marked trace, 1.11 per cent.; blood, numerous cells; pus, moderate amount; casts, very few hyaline; bacteria, slight bacteriuria; epithelia, numerous cells, probably from renal pelvis.

A nephrolithotomy of the left side was done on December 20. The kidney was found to be enlarged, its superior pole adherent to the pillar of the diaphragm, and numerous adhesions held it so firmly in its bed that it was impossible to dislodge it onto the loin. Consequently an incision was made in the cortex of the kidney and the stone separated from its bed with rapid sweeps of the finger. The kidney was at the bottom of a deep hole, which made the extraction of the stone difficult, and it was broken into three fragments. Before the stone was removed the surfaces of the wound were protected by layers of sterile gauze, but with the stone there came a little flow of purulent urine which had a perceptible ammoniacal odor. This was interesting, in view of the fact that the urine obtained by the ureter catheters was odorless. On account of the patient's condition failing, no attempt was made to suture the kidney, its cut surfaces being approximated and held by tampons. He had a rise of temperature of 101.8° F. on the second day, which persisted till the sixth day, after which he did well, but his pulse remained quick, never being less than 98. His physician had reported that the patient had had a quick pulse for several years and that it had ranged from 98 to 120. Primary union of the wound was secured, with the exception of the posterior end, where slight infection had taken place, and where the tampons had rested.

The stone showed concentric whitish deposits around small yellow nuclei. These deposits had probably been taking place for several years, thus preventing the escape through the ureter of the small primary concretions and coalescing to form the large and irregularly shaped stone which I now show you.

The radiographs herewith show the size and contour of the stone in each kidney. After an interval of a few weeks the stone will be removed from the right kidney.

40 East Forty-first Street.

SHORT TALKS WITH MY STUDENTS AND OTHERS: BEING RANDOM SUGGESTIONS FOR THE YOUNGER PRACTITIONERS.

By ROBERT H. M. DAWBARN, M.D.,

NEW YORK.

The short essays which follow have been taken from a collection of a hundred or more which, with those appearing in this and subsequent issues of the Medical Record, will be published later in book form.

Three things seem to me to call for prefatory comment: First the subject of memory-aids, mnemonics, etc. In the shape of acrostics and similar devices a few of these are included in this list—but only after some little hesitation, because of the Large Scorn with which so many of our professors view it. I use such things in trying now and again to supply a mental peg upon which to hang that dry clothing of the naked facts of science which constitutes a student's studies. Without that peg this clothing, wheresoever else bestowed, is apt in time gradually to slip to the floor of oblivion. It is the only instance in or out of the kingdom of parable, metaphor, and trope where dry clothing is not the preferable kind!

When one thinks of the enormous and steadily increasing number of things which at present one of these boys has to memorize, before he is permitted to reach up for that coveted parchment, I am beyond words thankful that I scraped through when I did! And I sympathize with him unto the extreme point of trying to help him in some practical way.

Many of the greatest anatomists and also surgeons have handed down to us aids of their own construction, or which antedate themselves. Some of these are known to be extremely old. Oliver Wendell Holmes when occupying "not a chair but a whole settee," as he put it, in Harvard medical faculty, thought it wise to help in this or any other possible way the struggling student. I know several anatomical mnemonics which he invented and used as a teacher. He was also not afraid—not a bit!—of a charge of losing his dignity. And, therefore, when in the course of his teaching—perhaps something difficult in physiology—he brought in just for a moment a sparkle of the fun that was so natural to him, it lightened up the dark places of the listening minds like a sudden ray of sunshine athwart gloom; gone as quickly, but not forgotten—far from it! And he is known to have said that this was the outcome of thought and not just for the sake of creating a laugh; that humor, brief and rather unexpected, is one of the best of all helps to fix a fact. I refer to him and a few others like-minded, great professors all, as my sufficient bulwark of defense when, as an experienced teacher, and because of such experience, holding their views, I choose to try helping students in a somewhat similar way.

This matter constitutes the second of the three points which, as said above, I wish to talk over with you here. For the third and last: It is inevitable that such short, condensed writings as are the "Thoughts" which follow must seem rather abrupt, perhaps even dogmatic. Every unnecessary word or phrase, including many which are courtesy expressions, has been cut out. With the same number of titles the book will be only about one-half the original manuscript length. This was done in part to save the time of the very busy men who may honor me by their attention, as also to aid concentration of thought upon the part allowed to remain, its essence or gist. I pray you then to absolve me from the mental charge of discourtesy and to believe that at heart I have the kindliest thought for each of you young brothers starting out on a difficult and—at least, for surgeons—very perilous sea, jeopardizing you as few other occupations do. If these suggestions shall succeed in preventing you from making some of the

numerous blunders by perpetrating which I learned better, I shall feel well content.

How to Select the Essentials for an Operation.—Think through the proposed work step by step; at each step lay out upon a large towel—or several of them—what is necessary for that particular procedure. Thus shall we avoid the personal mortification and very possibly real risk to our patient resultant from one or several serious omissions. For example: Anesthesia comes first; lay out drug and inhaler, also tongue-forceps, mouth-gag, and certain remedies commonly employed in case of collapse under anesthesia. Put in valise a bottle of tincture of iodine, both for use upon the skin just before cutting it and also probably to apply a light coat upon the wound surface just prior to closing it. These uses of iodine seem to me of such great value that I venture to think them permanent in the technique of the future. Next in thought the cutting begins. Bring forth the scalpels, also scissors, both curved and straight. Cutting implies bleeding; lay out a superabundant number of hemostats, by all means with slender and curved noses. Also we naturally think here of our gauze sponges and our catgut. (To hark back a bit, if the operation is to be in any region richly blood-supplied, never forget the large-sized rubber tubing wherewith to save blood, thus avoiding the chief cause of operative shock.) Milk—except in sepsis or malignancy—and then cord tightly if the cutting is to be upon a limb. If instead upon the head, neck, or trunk in an equally vascular place, use "sequestration anemia,"* that is (without milking), cord, but less tightly, and up at the very groin, accumulating (sequestrating) even quarts of blood in this lower extremity, or both of them, if desired; and thus making arterioles, when cut, hardly spurt at all; acting more like divided capillaries, indeed. To see clearly as we deepen the wound retractors will of course be needed. Do not select those with sharp points. They are an abomination, making multiple punctured wounds within the wound and therefore causing needless suffering the next day. Instead, lay dry gauze upon the wound-surface; retractors not sharp will not slip off of this. And so, step by step, complete the necessary list, remembering those which may be required in the various possible complications, and winding up with the means for closure, for drainage, if needed, and our dressings. Do not fail to write out, there and then, the complete list of things thus to be taken. After the operation hand this to the nurse having charge of cleaning your instruments and repacking everything. She is held responsible for seeing that nothing on that list is left behind—checking off each item from end to end. If this is *not* done (*i.e.* the list made at home and checked by her) it is surprising how many things will be lost in the course of a year of active surgical practice.

If this plan be regularly adopted, *i.e.* of thinking step by step through our proposed operation, and at each new point laying out the things necessary for its performance, then we can never make even the little omissions, unimportant but quite exasperating; still less will it ever be possible for us to blunder regarding something of vital importance, as once, while a very young surgeon, did that great operator, Professor Henry B. Sands, a man morally large enough to tell of his blunders and failures—and I know of no other way so reliable as this by which to differentiate and decide upon the true standing of any member of our profession. I was one of perhaps four hundred students who heard him tell the following incident of his career, using it as a warning to be more careful than he was, upon the occasion in question. He had been called, he said, to a farmhouse away out of town; indeed, some ten miles' drive from the railway station and nearly two miles from the nearest neighbor, in that rather newly settled region. Assisted by the country doctor who had sent for him to operate, he amputated a man's leg—for what disease Dr. Sands did not state; it has no bearing on the point. What he purposed doing was to saw across the femur at a level just a few fingers' breadth above the knee-joint; he could not secure skin enough for a disarticulation there. His flaps were cut accordingly, were retracted properly, and now he asked for the saw. Awful silence! He had neglected to bring one! Moreover, a hurried search disclosed the dread fact that no saw of any kind—and not even a chisel—was among the tools on that farm!

It is considered the more artistic and proper way to end a story, I believe, to avoid going too much into detail. Let the reader do a little thinking for himself. Pay him the compliment of assuming that he is able to do so. It may be that this thought was in Dr. Sands' mind at this point of his lecture. In any case that is where it ends. Each of his hearers was left to puzzle out for himself how best to get out of such an awful scrape. And if Dr. Sands' idea was that such puzzlement would be more apt to result in our never forgetting this story, then I agree with him.

Rush's Thunderbolt.—Jecor Asellus! What stout men were the old Continentals—able to survive one of these powders at a dose—and still proceed to whip the British as if nothing had happened! Never let it be said, however, that Washington's soldiers never ran. Impossible assertion. They had to! This combination is named after its parent, that Dr. Benjamin Rush who was Washington's friend, and who helped to finance the Revolution in the intervals when not prescribing his thunderbolt. This is a really superb prescription—a stroke of genius, and therefore simple. It consists of

℞ Calomel, gr. X
Ext. Jalapæ, gr. X

Mix well and make one powder. Sig.: To be taken at a dose.

For lo, these many years I have prescribed it (but in more merciful dosage) for each and every adult, with the fewest exceptions, upon entering the hospital to prepare for any major operation. I direct the druggist to divide the thunderbolt into four capsulesful, each dose being then one-fourth that advised by Rush. The patient is to take one of these with plenty of water, at once. Repeat each six hours until effective, or until all are taken. Seldom, indeed, is the fourth dose needed. It possesses several good points; for example, is practically tasteless—which becomes worth remembrance when by chance no capsules are to be had. It effectively stirs up the liver—and we have the dark-greenish calomel biliary movements in evidence thereof. It is a very thorough and also exceptionally reliable purgative. Again, it does not gripe while acting. And yet, as you all know, calomel alone gripes as a rule; it certainly does; and jalap—that dependable and otherwise excellent cathartic—has the same mean quality. But now observe this curious fact, that

*See "Sequestration Anemia," *Annals of Surgery*, February, 1907. Also note various ways of employing it in the index to the latest edition of Wyeth's "Surgery."

when we combine these, the resultant grayish powder possesses the good points of both and the bad points of neither! I have no explanatory theory. However, Professor Edward Curtis, who taught Materia Medica in Columbia Medical School, in my time, used to say that if we combine any two griping cathartics they will gripe each other and let the patient alone! Whether this is true elsewhere I cannot say. It is, however, in this instance—with fewer exceptions than accompany most rules affecting the action of drugs.

The Incised vs. the Lacerated Wound.—Do not change what should be a cleanly incised wound into a lacerated one by a multitude of little, trifling cuts. Make each stroke, whether of knife or scissors, accomplish something visible and worth while. (By-the-by, Dr. McBurney has repeatedly said that the older a surgeon the more he is inclined to use scissors rather than a scalpel. Following a long way after this great surgeon, let me say so, too.) The foregoing applies to cutting in a safe region; it is not meant to encourage reckless slashing, with possibility of consequent disasters. Only, it is obvious that if ten strokes are used where one would suffice, then the operator has multiplied by ten the chances that his wound will not heal kindly, being lacerated. When working in a region of jeopardy, however, do not use either knife or scissors at all—save when toughness of tissues compels an occasional cautious sharp touch. Instead, do the work by gauze.

Dry Gauze Sponge Dissection.—This great advance in technique has but comparatively recently come into general use. It renders very unlikely wounding of any important vessel, etc. However, it inevitably is followed by far more exudation of serum into the wound than ever is produced by a cutting-edge tool. And because serum (dead) would be splendid food for any stray microbes that may have gained entrance, here is almost the only instance where we need to drain an aseptic wound. A little roll of gutta percha tissue suffices—to be withdrawn upon the third day, or, indeed, as soon as the gauze dressing next the incision—in these cases to be frequently changed—is no longer moistened.

Ill-Smelling Matter Not Necessarily the More Poisonous; Blue Pus Not Very Objectionable.—Don't worry because the pus to which you have just given exit is foul of odor. It is, indeed, somewhat the more apt to be rather unobjectionable than the reverse. Of course, there may be a mingling of the very poisonous with the far less so. But sometimes deadly pus is wholly devoid of any bad smell; like that produced by the activities of the strepto-pyogenes, or the bac. tetani—which microbes are about as bad as possible. On the other hand, of the various stench-producing pathogenic organisms, those most apt to be found responsible for it are the bac. communis coli and the proteus vulgaris. Both are classed among the less poisonous microbes, relatively. Finally, when we find our dressings stained blue—or greenish, according to the degree of concentration, apparently—indicating the presence and activity of the bac. pyocyaneus, this will commonly prove a sign that the suppuration has taken a favorable turn, and before long is coming to an end.

Unspun Silk.—Is what, of course, it should be called. The customary name, "silk-worm gut," is a misnomer only exceeded in absurdity by the French title, "horsehair of Florence." And most of it (now) comes from Spain, too! The silk-worm is killed by dropping her into boiling vinegar. Fished out thence, the abdomen is broken open. The fluid coming forth is in consistency much like the contents of a soft gumdrop. This, if spun, would have been silk. It is not the silk-worm's gut, which has no tensile strength. This thick fluid is forced through a steel plate full of tiny holes, and in a very steamy atmosphere. The resulting threads, less than two feet each in length, are what we use in suturing, and what fishermen call "snell," and therewith connect the fish line to the fish hook. It is stronger than silver wire of the same caliber—unless you have sterilized it and tried to keep it some time thereafter. If, however, no such attempt is made, it remains, as bought, extremely strong for an indefinite number of years. When about to use it at an operation, take with you a sufficient number of these strands of *unspun silk*, and have them boiling in plain water while you are cutting. When needed have them brought, still in the boiling hot water; take them thence one at a time. Then you will have overcome the only serious fault this suture material has, namely, that used otherwise than hot, it does not hold a knot well. It should not be used for ligating, but only for sewing—mainly retention or relief suturing. It should not be buried. While sometimes Nature tolerates its presence within the body even a lifetime, yet not infrequent instances occur—it might be even after years of quiescence—indicating that it has become unwelcome; and a vigorous yet futile attempt is then made to destroy it by phagocytic activity. Of course, this results at last in a sinus, discharging pus at intervals, until the surgeon cuts down upon the cause and withdraws it. Even after years it is not found eroded, coming forth as smooth as when first used. It is probably its rigidity which causes it to annoy the tissues, when buried; the sharp, stiff ends, the rather large knot—for one should tie three times, for safety. Sterile linen, equally non-absorbable, does not seem to offend in the same way. It is a curious fact, the reason for which I do not know, that silk, both spun and unspun, is the only textile material of animal origin which is not ultimately digested and caused to disappear within the body. However, this statement should be modified by the remembrance that extremely fine silk ligatures have occasionally been known thus to melt away entirely—after a very long time.

Why Linen Thread Is Best.—Linen, silk, cotton, hemp, jute thread, one is tolerated as well as any other as a permanent resident within the human body. This was proven experimentally and beyond doubt some twenty years ago by Dr. Willy Meyer of this city. Silk weakens on boiling for asepsis. This is not true of the others. Silk is far more expensive than the rest, though this is a minor point. Of them all linen is strongest, hence, other things being equal, is preferable. I have not used either silk or any other of these save linen, for these many years; indeed not since that demonstration by Dr. Meyer. To "Pagenstecher" the pores of linen thread with celluloid, or anything whatever, is needless. Nobody does this to silk, yet its pores are not found objectionable. I use linen from the spool, such thread as is made for the seamstress, and have had no cause to regret it. Latterly it has come into general use, and deservedly so, particularly in intraperitoneal surgery. It may be wrapped about a gauze sponge and boiled with the instruments.

THE PHYSIOLOGICAL AND CLINICAL SIGNIFICANCE OF THE THYMUS.

IT has been generally accepted that the thymus gland, which reaches its greatest development at the end of the second year of life and then decreases until it almost disappears at puberty, is in some way obscurely associated with the early development of the organism. Apart from this and the vague notion that the thymus is a source of leucocytes and possibly of red blood cells, nothing has been known regarding the physiology of this organ. On the other hand, a great deal more has been learned about its pathological manifestations. As long ago as 1614 the association of sudden death with thymus hypertrophy had been recognized, and since that time the clinical picture of thymic asthma has been sharply defined. To this theory of the mechanical influence of the enlarged thymus there was added, in 1889, the conception of Paltauf, who in describing the lymphatic-chlorotic constitution, concluded that the hyperplastic thymus is not the real cause of sudden death, but is a part of the adenoid hyperplasia of the entire lymphatic system. This condition is associated with congenital narrowing of the arterial system and a dilated heart with muscular degeneration. The surgical relief of urgent paroxysmal dyspnea, which may be obtained by means of thymectomy, has amply demonstrated the mechanical rôle played by the enlarged thymus, while on the other hand, the association of enlarged thymus with other manifestations of lymphatism has been very frequently observed.

A most comprehensive investigation of the clinical and biological aspects of the thymus has recently been made by H. Klose and H. Vogt, who report their results in the *Beiträge für klinische Chirurgie*, Vol. LXIX, No. 1, 1910. They found that extirpation of the thymus in dogs at the period of its maximum development, namely, at the tenth to the twentieth day of life, is followed by a latent period of two to four weeks; then follows a stage of adiposity lasting for from two to three months; and finally the dogs fall into a stage of cachexia terminating in coma and death (*Cachexia thymopriva* and *Coma thymicum*). It would appear from these experiments that the thymus is an organ undoubtedly of vital significance in the animal economy.

In the human being extirpation of the thymus causes pronounced disturbances which are most marked after the second year of life, and which cause death at the age of puberty. Thymectomy at the period of the physiological development of the gland produces specific changes in the bony skeleton. The latter is retarded in growth, the bones become atrophic, and abnormally pliable and brittle. In the same individual there may result rachitis, osteomalacia, and osteoporosis. The cause of this osseous disturbance is the deficient deposition of lime salts, which in turn is dependent upon an increased formation of acids, particularly nucleinic acid. In addition to the bony changes there are marked nervous manifestations associated with edematous and degenerative phenomena in the central nervous system. The cachexia thymopriva is furthermore accompanied by an increased formation of fat and a hyperplasia of the spleen, pancreas, ovaries, and testes. Inasmuch as an organ that is hyperplastic has a tendency to perform its functions in an abnormal manner, similar to the condition of actual deprivation of the organ, it is concluded that children with an enlarged thymus is addition to the local effects have constitutional manifestations of the nature of an intoxication, manifestations corresponding to the lymphatic-chlorotic picture portrayed by Paltauf.

In the *Archiv für Kinderheilkunde*, Vol. LV, Nos. 1 and 2, H. Klose, in describing and commenting upon the above investigations, points out their pediatric significance. He regards the thymus as an organ that inhibits the formation of acids in the body, or neutralizes or masks an excessive formation of acids. It is conceived that in the higher animals the thymus, a gland which is very rich in nuclein, may not improbably be the chief depot for the synthesis of nuclein. Thymectomy causes an intoxication of the organism from an excess of nucleinic acids, a condition identical with that described by Hoeltzner under the name of oxypathy. It is to this acid intoxication that are attributed the bony dystrophies and nervous derangements of the cachexia thymopriva.

Investigations along the same lines have been performed, with somewhat different results, by O. Nordmann, who describes his experiments in the *Archiv für klinische Chirurgie*, Vol. XCII, No. 4, 1910. Extirpation of the thymus in animals was followed by wasting and by suppurative manifestations in the skin, upon which it is concluded that thymectomy diminishes the bacterial resistance of the body. The growth of the bone was not affected. None of the animals operated upon lived more than one year and the immediate cause of death was an enormous dilatation of the heart. In the same journal H. Klose notes that partial extirpation of the thymus at the height of its development, and total extirpation during the period of its normal involution are followed by no permanent ill effects. The spleen may compensate for the loss of the thymus. The administration of thymus extract cannot supply the deficiency in the normal gland but the administration of alkalies is in such cases of therapeutic value in counteracting the bad results of this deficiency.

ANNUAL REPORT OF THE SURGEON-GENERAL OF THE PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

The first part of this report deals with antiplague operations. In San Francisco the crusade against plague has been continued with unremitting vigor. It is satisfactory to note that during the past eighteen months there has been a remarkable diminution of fleas in San Francisco, and "it is believed that general cleanliness in house, yard, and cellar, the use of chlorinated lime in such places, together with the renovation of stables, has practically abated the flea nuisance in San Francisco." The crusade against ground squirrels in Contra Costa County, Cal., is referred to, as is also the war against rats in Seattle, Wash.

The investigations of typhoid fever in Washington, D. C., by the board appointed for that purpose in July, 1906, have continued. The summary of the three years' studies is in brief as follows: It has been shown that typhoid fever has a distinct seasonal prevalence and it was found that every case of clinical typhoid fever in Washington was reported to the health officer, which is in marked contrast to Koch's findings and investigations in Trier. The disease has been discovered to be especially prevalent among children, suggesting that milk and contact are more prominent factors in its dissemination than they can be definitely proven to be. Little relation could be discovered between the seasonal curve and the prevalence of the disease, and evidence was lacking to support the supposition that day servants frequently convey infection to the households of their employers. The investigations have shown that contact is one of the major factors in the spread of the disease in Washington at the present time. Pasteurization of milk is recommended by the board for the reason that 10 per cent. of the cases studied during the three years have been definitely attributed to infected milk and it is thought that pasteurization conducted under official supervision would materially reduce the prevalence of typhoid fever.

Pellagra is dealt with at considerable length and the valuable researches of Passed Assistant Surgeon Lavinder are made the subject for comment. As to its etiology the view is expressed in the report that the long held belief in a relation between pellagra and the use of corn as food would seem to be too universal to permit of its rejection except in the case of demonstrative proof to the contrary. Attention is drawn to the need for greater precautions in the case of lepers than is practised at the present time in certain parts of this country. It is pointed out that in some States segregation is practised, but in others there is no isolation or segregation, and in New York City, with a congestion of population which would furnish good opportunities for transmission, segregation is not practised. The writer does not seem to see, however, that the fact that the disease does not spread in this city under such circumstances is fairly conclusive proof that strict segregation is not necessary.

Reference is made to the work of the hygienic laboratory in detail, and a plea is urged for the enlargement of the building and of the personnel. A review is given of the operations of the service in the Philippine Islands, and it is shown that under the able supervision of Assistant Surgeon Victor C. Heiser, chief quarantine officer for the Philippines, who is also commissioner of health for the insular government, quarantine, disinfection of ships, and all other sanitary arrangements which come under the scope of his authority have been carried on in a very satisfactory manner. There have been no cases of plague in the Philippines since April, 1906, and considering the fact that these islands are in almost daily communication with neighboring countries which are plague infected this is a somewhat remarkable circumstance. The freedom from plague of the Philippines may be attributed to the extreme diligence with which measures calculated to keep away plague are pursued and in this respect the islands may be regarded as an object lesson to other countries of the Far East.

At the end of the report Dr. Wyman contributes a paper on public health problems, the main features of which are clearly discussed. Water pollution on a large scale is manifestly the most important public health problem of the present period and Wyman deals with it, or rather reviews it, from the legal standpoint. The legal problem, indeed, is more difficult of solution than is the sanitary, because it is not known how the matter stands so far as legal points are concerned. Can the Federal Government step in and compel State authorities to prevent rivers, lakes, and water supplies generally from becoming polluted to the menace of the entire community? According to Wyman this very question is now engaging the careful thought of men eminent in the legal as well as in the medical profession. From a perusal of the statements by Hon. George Shiras, furnished to Wyman and published in the report, it appears that it will be left to the Supreme Court of the United States to decide as to whether the pollution of interstate waters is a matter for Federal intervention. If the court decides that it is "such an established jurisdiction must include the right of Congress to legislate in accordance therewith."

The report throughout is a valuable document and exhibits in a most conclusive manner the untiring energy and zeal of the Public Health and Marine-Hospital Service in the cause of public health. It is indeed a strong argument in support of the Mann bill now before Congress enlarging the powers of this bureau.

THE UNFIT.

In the *Glasgow Medical Journal* for January, Dr. W. H. Sinclair, Prison Surgeon at Barlinnie, Scotland, writes on the unfit. He defines the unfit for the purpose of his paper as the always tired, the loafer, and unemployed, the feeble-minded, the epileptic, the criminal, and the alcoholic. The paper is lengthy, and there is only space here to touch upon a few of its most interesting points. Referring to the always tired, Sinclair thinks with Sir Lauder Brunton that there may be a relation-

ship between intestinal toxemia and the statement which is put into the mouth of the British workman, "I eats well, I drinks well, and I sleeps well, but when I sees a bit of work coming along I'm all of a tremble."

With regard to the feeble-minded the writer makes a statement which, if it is a fact, brings up a matter of the most serious import. He says that most weak minded men have strong sexual desire, and that the percentage of illegitimate children given birth to by feeble-minded women considerably exceeds the percentage of illegitimate births of the whole population. The average number of children in a normal family is four; the average number in a degenerate family is seven.

Sinclair's conclusions are as follows: There is a large and increasing number of the unfit. The influence of such persons is hurtful to the community, leading to the production of undesirable stock and to large public expense. Legislation for the care and control of the unfit in their own interests and in the interests of the race is urgently called for. The physically capable and noncriminal among the unfit would probably be suitably dealt with in farm and labor colonies. Notification and registration are probably necessary as a preliminary to the care and control of epileptics. Much attention should be bestowed on the health and training of epileptic children when possible by parents, otherwise by the State. The marriage of an epileptic should be prohibited by law. Epileptics improperly cared for by their relatives should be put under care and treatment in epileptic colonies. The shutting up for the natural term of their lives of incorrigible and irresponsible inebriates is highly desirable in their own interests and in the interests of the community. A simple and easy method of finding the feeble-minded, such as notification, is probably practicable. Legislation to facilitate certification and to provide for the continued supervision or, if necessary, confinement of the feeble-minded is urgently required.

It is not only in Great Britain that such regulations as sketched above or regulations of a similar character might be of benefit to the community at large. In this country there is a large population of the unfit and the problem as to how to deal successfully with this army of undesirables is hard to solve. Any practical suggestions to this end should therefore be welcomed.

The Antivivisectionists.

The yearly renewed activities of the so-called zoophilists have already acquired the characteristics of an annual epidemic visitation. They are again storming the citadel of our legislators, this time with a bill introduced at Albany to "investigate the abuses of vivisection." The forces of science and of humanity must again be assembled to meet the deluded foe; the time-worn arguments of the "anti's" must be met with renewed vigor, and their exaggerations and falsehoods laid bare without mercy. The pencil of the cartoonist in *Puck* of February 22 has admirably presented the entire argument of both sides better than all the floods of eloquence that have overwhelmed the public press for many years. The picture, by Cranford, is entitled "Vivisection." It portrays the investigator at work in his laboratory, performing an experiment upon a rabbit that is being anesthetized by an assistant. A party of antivivisectionists has interrupted the work, and standing at one side of the laboratory table, with facial expression and upraised fingers indicating their horror at the unutterable cruelties which they fancy are being inflicted upon the dumb creature, they, "the sentimentalists," exclaim, "for mercy's sake, stop." At the opposite end of the table there is a different group, entitled "the sufferers," in shadowy outline they crowd forward—the ghastly, emaciated forms of the dying, the incurable, and the crippled, young and old—appealing with one voice to the vivisectionist, "for humanity's sake go on." Yes, in the name of humanity vivisection must go on!

Relations of Freud's Neurosis Doctrine to the Practitioner.

One of the weak points of Freud's theory is the difficulty of summing it up in a concise manner. Neither the author nor any of his disciples have succeeded in such a task, and perhaps have not even seriously attempted it. Freud has preferred to teach by case histories rather than by precepts. At a discussion of Dr. Stegmann's paper before the Society of Naturalists and Physicians of Dresden (*Münchener medizinische Wochenschrift*, January 31) the lecturer admitted that a complete summary of Freud's views lies beyond the compass of a single address. The most that can be done is to touch on the salient points. He then repeated these as they are commonly accepted. In the discussion which followed, Rietschel, a pediatrist, opposed Freud's doctrines because they comprise almost the entire domain of the neuropathy of childhood. Forced interpretations, endless artificiality, result from the application of the method. Haenel believed that the restoration of the sexual origin of hysteria marks an advance rather than a relapse. In closing Stegmann stated that Freud had always avoided committing himself to a system, and indeed his views had undergone changes. Thus he had long ago abandoned the teaching that sexual psychic trauma is the chief cause of hysteria.

News of the Week.

New Jersey Medical Practice Law.—The New Jersey State Legislature has under consideration a bill designed to raise the standard of requirements for medical licenses in that State. The new bill provides for the appointment by the Governor of a board of examiners to consist of nine regularly licensed physicians, to which applicants for licenses to practise medicine shall submit satisfactory evidence of both preliminary and medical education. For the present the bill fixes the requirement of preliminary education at four years of high school work or its equivalent, but provides that in July, 1915, this requirement shall be raised to one year of academic work before taking up the study of medicine and that the standard shall be raised each year, until in July, 1918, four years of academic work shall be required. A candidate then must hold, in addition to his M.D., either a B.S. or a B.A. degree. Suitable provision is made for the admission to examinations of candidates who received their degrees prior to the passage of the bill. The enactment of such a law would raise the standard

of the medical profession in New Jersey so high that there would be no difficulty about the acceptance of the State certificates by other States. The bill also aims to change the definition of "practising medicine and surgery" so as to include the practice of osteopathy, and it is therefore likely to meet with opposition from the osteopaths who are urging the passage of a measure providing for licensing members of that school.

For Military Hospital.—A memorial to Congress asking that a Naval and Military Hospital and Sanatorium be established at the Hot Springs north of Salt Lake and offering a site free of cost to the Government has been adopted by both branches of the Utah Legislature. A bill with the same object will be introduced into the House of Representatives.

Appointments at the Presbyterian Hospital.—As a result of the recent tentative agreement between Columbia University and the Presbyterian Hospital, New York, the appointments of Dr. Theodore C. Janeway as attending physician and of Dr. William G. MacCallum as pathologist to the hospital have been announced. Dr. Janeway is professor of the practice of medicine in the College of Physicians and Surgeons and Dr. MacCallum is professor of pathology. They succeed Dr. W. Gilman Thompson and Dr. Eugene L. Opie, respectively, at the hospital. The final agreement between the two institutions has not yet been signed, but the trustees are proceeding on a tentative plan pending the settlement of the many details involved.

Diphtheria at Johns Hopkins.—Thirty cases of diphtheria are reported among the nurses, students and patients of the Johns Hopkins Hospital, which has been practically quarantined on account of the epidemic. It has been found necessary to close the operating rooms and to remove many of the patients to other institutions. The medical school also has been closed and the students dismissed until danger of further spread of the infection is over.

Aged Woman Dies.—Mrs. Simla Silverman of Brooklyn, N. Y., a native of Warsaw, who saw Napoleon on his retreat from Moscow in 1812, died suddenly at her home on February 25, aged 104 years.

To Handle Contagious Cases.—By a recent order of the Board of Health of Boston, all cases of infectious disease occurring in that city are in charge of four nurses appointed by the board. When any such case is reported the nurse visits the house, superintends the removal of the patient to the hospital or the establishment of a satisfactory quarantine and sees that proper precautions are taken by the other residents of the house.

Chinese Fight Plague.—The people of China seem at last to have been aroused to the seriousness of the situation as regards the plague and to the necessity of enforcing sanitary measures to prevent its further spread. Instructions have been issued that every village must burn its dead and the superstition against such disposition has apparently been overcome. In some villages the bodies placed in the streets by relatives are collected on sleds by masked men and transported to the cremation grounds where they are burned. All the inhabitants of one small village near Harbin, Manchuria, were recently found dead, many of the bodies lying in the open covered with snow. In Harbin itself there have been from twenty to forty deaths a day. Both France and Germany have ordered stricter regulations and quarantine against persons arriving from China, and Russia has sent a number of physicians and nurses to China to aid in the suppression of the epidemic.

Antituberculosis Associations.—Associations for the prevention of tuberculosis have been formed in Cuba, Porto Rico, and Trinidad. In Cuba it is estimated that the deaths from this disease number more than 40,000 a year, the death rate being nearly three times as high as in the United States. In Porto Rico there are over 6,000 deaths every year from tuberculosis out of one million inhabitants. Conditions in other islands of the West Indies are even worse, the chief reason being found in the unsanitary dwellings of the native islanders.

The German Hospital.—The report of the work of the German Hospital, New York, during the past year was presented at the annual meeting of the Board of Trustees, held recently. A total of 45,703 patients were treated at the institution, of whom 6,490 were received into the hospital, 32,845 were treated in the dispensary and 3,724 were attended by visiting district physicians. The total current expenses amount to $215,066. Gifts and bequests, in the sum of $67,771, were received during the year, in addition to a gift of $100,000 from Mrs. Anna Woerishoffer to aid in the establishment of a children's department. Mr. Adolph Kuttroff was reelected president of the hospital. It was announced that clinical instruction will be given hereafter in the wards of the hospital to students from the College of Physicians and Surgeons, Columbia University.

Mumps at Cornell.—An epidemic of mumps is reported at Cornell University, Ithaca, N. Y., which is serious enough to overtax the infirmary accommodations in spite of the fact that only last fall a new ward for contagious cases was opened. The university authorities are trying to rent houses which can be fitted up as isolation wards temporarily.

The German Census.—The census of the German Empire, which was completed last December, gives the total population as 64,896,881, an increase of 4,455,392 over 1905. The rate of increase during the five years was only 7.02 per cent., as against 7.58 for the five years previous, and the specter of race suicide is seen hovering over the empire.

St. Francis Hospital.—The new wing of St. Francis Hospital at Brook and St. Ann's avenues, New York, was opened on February 22, its completion rounding out the original plans for the entire hospital. The building will be used as living rooms for the house staff and the hospital servants. The basement contains a gymnasium and billiard rooms, while on the third floor there are the library and the baths.

Typhoid Fever Epidemic.—From Erie, Pa., comes the report of an epidemic of typhoid fever, more than six hundred cases having occurred since the first of the year, with some fifty deaths.

Dr. Frederick J. Leviseur of New York has been appointed consulting dermatologist to the Montefiore Home.

Dr. I. L. Nascher of New York delivered a lecture on geriatrics before the Bennett Medical College, Chicago, on February 28. It is announced that Bennett Medical College will probably include a course on the physiology and pathology of old age in its curriculum next year.

Charitable Gifts.—Mr. Melville W. De Wolf

of New York, who died recently, left a bequest of $5,000 to the Presbyterian Hospital to establish the Emma De Wolf bed for children, and the same amount to the Roosevelt Hospital to establish the Carlton De Wolf free bed.

The Chair of Medicine at the University of Pennsylvania.—Dr. Alfred Stengel will succeed Dr. David L. Edsall as professor of medicine at the University of Pennsylvania. It was believed that Dr. John H. Musser would be appointed to the vacant chair, as he was the choice of the University authorities and was supported by Dr. Stengel, who is said to have refused to be considered a candidate until Dr. Musser had definitely announced that he was unable to accept the position. Dr. Musser did so announce in a letter to the Medical Council and Dr. Stengel was thereupon unanimously elected.

Dr. Winford H. Smith, after two years of service as general medical superintendent of Bellevue Hospital, New York, has resigned to accept the position of superintendent of the Johns Hopkins Hospital, Baltimore, succeeding in the latter post Dr. Henry M. Hurd, who retires after twenty-five years as head of the hospital. Dr. Smith was graduated from Johns Hopkins Medical College in 1903. It is understood that he will spend two months abroad, studying the hospitals of England and France, before taking up his new work.

Mt. Sinai Nurses.—Forty-six nurses were graduated from the Mount Sinai Hospital Training School on February 22, exercises being held in the hospital. Dr. Thomas R. Slicer and Mr. George Blumenthal, president of the hospital, addressed the graduates.

New University Infirmary.—Coincident with a scarlet fever scare at Colgate University, Utica, N. Y., announcement has been made of the anonymous gift of a sum of money sufficient to build, equip, and maintain a college infirmary. It is hoped that this will be ready for use in the fall of 1911.

Lutheran Hospital.—The Society of the Lutheran Hospital, which was recently organized, has received a gift of a plot of land near Central Islip, Long Island, on which to erect a home for convalescents.

Société Internationale de Chirurgie.—The third congress of the International Society of Surgery will be held at Brussels on September 26 to 30, 1911. The congress will include an exhibit of material relating to the treatment and study of fractures, and an exposition of apparatus and surgical instruments. The deliberations of the congress will be centered upon three subjects: Surgery of the lungs and pleura; colitis, and pancreatitis. The secretary-general is M. le Professeur DePage, 75 avenue Louise, Bruxelles.

Eastern Medical Society.—Arrangements have been completed for holding the annual dinner and dance of the society at the Hotel Astor, New York, on the evening of Wednesday, March 22. Addresses will be made by the Hon. John A. Dix, Governor of the State of New York; the Hon. John Temple Graves, and others; and the dinner will be made the occasion of the presentation of a testimonial to Dr. Abraham Jacobi, an honorary member of the society. Tickets may be obtained from the secretary, Dr. Lewis T. Griffith, 616 Madison avenue.

Deutsche Gesellschaft für Urologie.—The third congress of the German Urological Society will be held on September 11, 12, and 13, 1911, in Vienna, under the presidency of Prof. O. Zuckerkandl. The discussions of the congress will be divided into two main heads: I. The Result of Nephrectomy for Tuberculosis, and II. The Importance of Urethroscopic Methods for the Clinic. A final program will be issued some time in July.

Third International Laryngo-Rhinological Congress.—This congress will meet in Berlin from August 30 to September 2, 1911, under the presidency of Professor B. Fränkel. The secretary of the congress is Professor Rosenberg, Berlin N. W., Schiffbauerdamm 26.

The Fifteenth International Congress on Hygiene and Demography.—The congress, which will be the first on hygiene and demography to meet outside of Europe, will be held in Washington, September 23 to 28, 1912. The Department of State has assumed responsibility of the conduct of the congress. President Taft has consented to act as honorary president, and the official invitation has already been accepted by twenty foreign governments. Dr. Henry P. Wolcott is the president of the congress, at which the United States will have an opportunity to make known its sanitary achievements in the Canal Zone, Cuba, Porto Rico, the Philippines, and Hawaii. It is earnestly desired that physicians and others interested in the subject of hygiene shall signify their intention of becoming members of the congress to Dr. John S. Fulton, secretary-general, Army Medical Museum, Washington, D. C.

The Late Dr. Lustgarten.—At a meeting of the medical board of the Montefiore Home, held February 12, the following resolution was adopted: "It is with profound regret that we record the death of Dr. Sigmund Lustgarten, for many years attending dermatologist and member of the Medical Board of the Montefiore Home. Dr. Lustgarten was one of the leaders in his specialty, a man of broad interests, sound judgment, strong and attractive personality. His untimely death is a great loss to the medical profession, as well as to this board, on which he served for many years. Resolved, That our heartfelt sympathy be extended to his bereaved family in their irreparable loss. And be it further Resolved, That these resolutions be spread upon the records of this board and that a copy be presented to his family. Resolved furthermore, That copies of these resolutions be sent to the MEDICAL RECORD, *Medical Journal*, and Board of Directors. (Signed) EDWIN BEER, M.D., Secretary of the Medical Board.

The Late Dr. Kipp.—The New York Ophthalmological Society has heard with profound regret of the death of Dr. Charles J. Kipp, one of its oldest members. Dr. Kipp was born in Hannover, Germany, on October 22, 1838, and died of pneumonia after a brief illness on January 13, 1911. He came to the United States at the age of 16. He was graduated from the College of Physicians and Surgeons, New York City, in the class of 1861. Shortly after his graduation he joined the army as assistant surgeon, and served throughout the Civil War. In 1864 he was promoted to be surgeon, with a brevet rank of Lieutenant-Colonel. He resigned from the army in 1868 and devoted himself to the study of eye and ear diseases. Settling in Newark, he opened the outdoor department for eye and ear diseases in St. Michael's Hospital. Later he founded the Newark Eye and Ear Infirmary, where he filled the position of executive surgeon until his death. Though living at a distance, he regularly attended the meet-

ings of this society and took an active part in its proceedings. From 1885-1886 he was its president. His sterling qualities, his painstaking care, his sincerity, and kindness, endeared him not only to his friends, but to the public at large. The profession bestowed on him its highest honors. He was at one time president of the Medical Society of the State of New Jersey; one of the vice-presidents of the American Medical Association; from 1907-1908 president of the American Ophthalmological Society; later president of the American Otological Society. His contributions to medical literature were numerous and valuable. He was the first to recognize that otitic thrombosis of the lateral sinus was frequently accompanied by optic neuritis. In 1876 he read a paper before the International Ophthalmological Congress, held in New York, on "Subconjunctival Cysticerous," probably the first case ever described in America. This society loses in the death of Dr. Kipp a staunch and energetic friend, an experienced and indefatigable worker, one whose qualities of heart and mind won the affection and respect of all who came in contact with him. In commemoration of his useful and beautiful life, your committee recommend that this "In Memoriam" be spread upon the minutes of the society, and that a copy be sent to his next of kin and to the medical press. (Signed) Emil Gruening, Thomas R. Pooley, Peter A. Callau.

Obituary Notes.—Dr. J. B. Walker, a physician and surgeon of thirty years' practice in Effingham, Ill., died suddenly at his home of cerebral hemorrhage on February 11, aged 54 years. He was graduated in 1882 from the Miami Medical College of Cincinnati, O., and in 1899 took courses at the New York Post Graduate School and the New York Polyclinic. He was a member of the American Medical Association, Illinois State Medical Society, and Æsculapian Society of the Wabash Valley. Ex-Governor Yates and Governor Deneen had appointed him to the Congress of Tuberculosis in New York and Washington, D. C.

Dr. Thomas Markley Trego of Albany, N. Y., a graduate of the College of Physicians and Surgeons, New York, in 1874, attending physician to the Child's Hospital and the Home for Aged Men, consulting physician to the Albany Orphan Asylum, and a member of the New York State and Albany County Medical Societies, died at his home as the result of an accident, on February 16, aged 63 years.

Dr. Edward Hitchcock, professor of hygiene and physical education at Amherst College, Massachusetts, a graduate of Amherst in 1849, and of the Harvard University Medical School in 1853, a member of the teaching staff at Amherst since 1861, and dean of the Faculty since 1899, died at his home on February 15, aged 82 years.

Dr. Edward Strong Bogert, Medical Director, United States Navy, retired, a graduate of the Medical Department of New York University in 1860, appointed assistant surgeon in the United States Navy in 1861, made medical director in 1889; in charge of the Naval Hospital, New York, 1892-95; retired in 1898, and advanced to the rank of rear admiral in recognition of his services during the Civil War, 1906, died at his home on February 16, aged 74 years.

Dr. Edwin D. Leidy of Flemington, N. J., a graduate of the Jefferson Medical College, Philadelphia, in 1885, a member of the American Medical Association, and the New Jersey State and Hunterdon County Medical Societies, died at his home on February 17, aged 52 years.

Dr. John A. Rynard of Harrisburg, Pa., a graduate of the Jefferson Medical College, Philadelphia, in 1872; formerly surgeon to the Pennsylvania Railroad, died at his home on February 10, aged 72 years.

Dr. Samuel D. Hopkins of Denver, Col., a graduate of the Medical Department of the University of Pennsylvanbia in 1893, a member of the American Medical Association, the American Neurological Society, the Colorado State and Denver County and City Medical Societies, and the Denver Clinical and Pathological Society, neurologist to the Denver County Hospital, St. Joseph's Hospital, and the Mercy Sanatorium, and professor of neurology in the Denver and Gross College of Medicine, died at St. Joseph's Hospital, Denver, of appendicitis, on February 4, aged 39 years.

Dr. Joseph Buchanan Walker of Effingham, Ill., a graduate of the Miami Medical College of Cincinnati in 1882, a member of the American Medical Association, and the Illinois State and Effingham County Medical Societies, and attending physician to St. Andrew's Hospital, died at his home suddenly on February 11, aged 53 years.

Dr. Lincoln D. Foreman of Peoria, Ill., a graduate of the American Medical College of St. Louis in 1881, died suddenly on February 9, aged 49 years.

Dr. John C. Cockburn of Minneapolis, Minn., a graduate of the Harvard University Medical School in 1872, a member of the American Medical Association, and the Minnesota State and Hennepin County Medical Societies, died at his home on February 5, aged 69 years.

Dr. John C. McClung of Leipsic, Ohio, a graduate of the Western Reserve University Medical College, Cleveland, in 1873, died at his home on February 3, aged 67 years.

Dr. Henry M. Shaw of Shawboro, N. C., a graduate of the Washington University School of Medicine, Pa., in 1871, and a member of the North Carolina State and Currituck County Medical Societies, died suddenly on February 9, aged 63 years.

Dr. Benjamin T. Abbott of Ocean City, N. J., a graduate of the Jefferson Medical College, Philadelphia, in 1870, and a member of the American Medical Association, and the New Jersey State and Cape May County Medical Societies, died suddenly on February 17, aged 67 years.

Dr. Floyd Preston Sheldon of New York, a graduate of the University of Michigan Department of Medicine and Surgery in 1878, a member of the New York County Homeopathic Society and of the Academy of Pathological Science, surgeon to the Harlem Homeopathic Hospital, and oculist to the Webb Home and Home for the Friendless, died at his home on February 18, aged 52 years.

Dr. Albert Sydney Ashmead of New York, a graduate of the Department of Medicine of the University of Pennsylvania, formerly foreign medical director of the Imperial Japanese Hospital, Tokio, and an authority on Asiatic diseases, died at the Jefferson Hospital, Philadelphia, on February 20, aged 61 years.

Dr. James P. Burke of Meridianville, Ala., a graduate of the Department of Medicine of the University of Pennsylvania in 1853, and a member of the Alabama State and Madison County Medical Societies, died at his home after a long illness on February 12, aged 80 years.

Obituary.

ALOYSIUS OLIVER JOSEPH KELLY, M.D.

PHILADELPHIA.

Dr. Aloysius O. J. Kelly of Philadelphia died at his home, on February 23, after a short illness. Dr. Kelly was born in Philadelphia on June 13, 1870, and was graduated from the Medical Department of the University of Pennsylvania in 1891, afterward becoming resident physician at St. Agnes' Hospital, and still later taking postgraduate courses at the University of Vienna. Returning to Philadelphia to practise he was, in 1896, appointed instructor in physical diagnosis in the university. In 1899 he was made instructor in clinical medicine, was advanced to associate in 1902, and since 1906 had been assistant professor in the same department. He also served as assistant physician to the University Hospital, physician to St. Agnes' Hospital, and pathologist to the German Hospital, Philadelphia. In 1897 he was made clinical professor of pathology in the Woman's Medical College of Pennsylvania, and had been a full professor since 1906. He also held the chair of the theory and practice of medicine in the University of Vermont. He was a member of the American Medical Association, the Association of American Physicians, the American Association of Pathologists and Bacteriologists, the American Academy of Medicine, the College of Physicians of Philadelphia, the Pennsylvania State and Philadelphia County Medical Societies, the Philadelphia Pathological, Pediatric, and Neurological Societies, and the Interurban Clinical Club. In addition to his practice and teaching work, Dr. Kelly found time to devote to the literary side of medicine, editing the "International Clinics" from 1903 to 1906, and since 1906 conducting with great success the *American Journal of the Medical Sciences*. He was the author of a "Practice of Medicine," and was coeditor with Dr. J. H. Musser of a "System of Therapeutics."

Correspondence.

THE ENTITY OF AN INFECTIOUS DISEASE OF UNKNOWN ORIGIN.

To the Editor of the Medical Record:

Sir:—May I ask you in justice to the cause of clinical medicine to correct the impression which your report gives of the findings of the committee appointed to investigate the "Infectious Disease of Unknown Origin," as observed by Dr. Nathan E. Brill, as it appeared in the Medical Record January 28, 1911, page 182.

Your report makes no mention of the *positive* findings of the committee which unanimously resolved that the disease reported by me represents a distinct clinical picture and should be entitled to recognition as an entity. Had this preceded in your issue the terminal paragraph which stated that "the evidence at hand did not seem sufficient to decide whether these cases represented an atypical form of some already recognized disease other than typhoid or paratyphoid fever, or were instances of a disease hitherto unrecognized," no misinterpretation of the meaning of the committee could occur. As it is the criticism might be made that the committee, believing the disease to represent a definite clinical entity of an already recognized disease, still failed to say what such already recognized disease was. Only the complete report of the committee can give its true meaning. It is as follows: (1) The cases seen by the members of this committee correspond with Dr. Brill's description. (2) The cases present a fairly uniform symptomatic picture and seem to the committee to be entitled to recognition as a clinical group. (3) The clinical picture is quite distinct from that of ordinary typhoid fever. (4) The evidence seems conclusive that they are not cases of infection with the typhoid or paratyphoid bacillus. (5) The evidence at hand does not seem sufficient to decide whether these cases represent an atypical form of some already recognized disease other than typhoid or paratyphoid fever, or are instances of a disease hitherto unrecognized.

Nathan E. Brill, M.D.

48 West Seventy-sixth Street.

STERILITY IN WOMAN AND IN MAN.

To the Editor of the Medical Record:

Sir:—I read Dr. A. J. Rongy's paper on "Primary Sterility in Women," in the Medical Record of February 18, with great pleasure and interest. His paper is particularly valuable for calling attention to the undeserved blame which woman has been carrying for so many centuries, as being the chief factor when no offspring was forthcoming. From my personal experience in cases of barren marriages the man is guilty in about 80 per cent.; either directly, because suffering from azoospermia, bilateral gonorrheal epididymitis, atrophy of the testicles due to excessive, so-called "furious," masturbation, impotentia coeundi, monorchidism, cryptorchidism, etc., or indirectly by having infected the woman and having diseased her endometrium and sealed her Fallopian tubes. Only too often, even at the present day, is the woman dilated, curetted, painted, tamponed, operated upon, and otherwise maltreated and humiliated, when the fault is exclusively with the man. This is a fact which cannot be repeated too often. There is a peculiar condition which we sometimes meet in our cases of sterility, and for which no satisfactory explanation has yet been offered. Mr. and Mrs. Smith have been living together for ten or fifteen years without any issue. No abnormality can be discovered in either husband or wife. Mr. and Mrs. Smith divorce. Mr. Smith marries another woman, Mrs. Smith marries another man. And both women conceive and bear children regularly afterward. How to explain this phenomenon? William J. Robinson, M.D.

12 Mt. Morris Park West.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

RATS AND PLAGUE—RESPIRATORY MOVEMENTS IN PERITONITIS—EYE SYMPTOMS IN ACROMEGALY—AUSCULTATION OF JOINTS—MEDICAL STATE OF ESKIMO—PLAGUE EXPERT FOR CHINA—SPECTACLE WORKERS AND DOCTORS—ITEMS.

London, February 10, 1911.

Rats are more than holding their own as a subject of discussion—they have, as such, even penetrated the precincts of the Guildhall, where the Lord Mayor on Monday presided over a meeting of municipal and sanitary authorities convened by the Royal Institute of Public Health. The object was to show that it was high time to set in motion a

scheme for the extermination of the rodent, not only in London, but throughout the kingdom. Of course it is as a conveyor of plague that the Institute takes up the matter, although other objections to the rat, and, indeed, all vermin, deserve consideration. The Lord Mayor said the corporation had been doing a great deal; last year 12,000 rats were caught in the Central Market alone. His Lordship was followed by Sir Crichton Browne, who, with his usual energy, proposed a resolution for effective measures to be organized in all countries and the cooperation of the medical officers to be sought. He said there was no cause for panic; skillful watchers were on the lookout, and their sanitary house was set in order.

But there was cause for anxiety as long as a bacillus-infected rat remained in the land. Half a dozen deaths had wakened us up, but in India plague had killed 5,000,000 persons in the last decade, and at this moment ghastly scenes were being enacted in China. Rats had no business here. They were clever, very clever, but altogether reprobate. It had been said they were good scavangers, but it would be a sorry sanitary system that left them to do such work, for they did even there infinitely more harm than good. They destroyed grain to the value of some millions per annum. Professor Sims Woodhead seconded the motion, which was carried. Another resolution was passed urging the appointment of a royal commission to inquire into (1) the increase of vermin and the steps to be taken for their destruction; (2) which are not harmful; (3) the safety and efficiency of the various viruses on the market, and other means advocated for their destruction.

A further indication that the subject is obtaining attention is the appearance in the *Times* of a contribution by Dr. Sambon, who points out the risks of the spread of plague wherever it finds an entrance. He says not only rats, but cats, squirrels, hares (shall we say all fur-bearing animals?) dogs, sheep, cattle, and poultry may convey the infection. Yet he remarks that the only way to preserve immunity anywhere is to keep out plague-infected rats. He declares further that, contrary to the general opinion, transmission from person to person is, during an epidemic, more common than from animal to man. The disease spreads first from one set of animals to another. The germ in passing through an animal undergoes changes—it may have its virulence thereby increased or diminished. The rat strain of *Bacillus pestis* may be replaced by a human strain. The rat flea may give place to other fleas, *e.g.* those of the dog and cat, both of which attack man almost as readily as his own variety.

At the Ophthalmological Society the relation of ocular symptoms to acromegaly was discussed apropos of a paper by Mr. Herbert Fisher. Having referred to the work of Cushing and Pavlesco, he related nine cases of pituitary body and chiasma lesion he had observed, mostly over a long time. There were examples of acromegaly and of Fröhlich's syndrome, complete and partial. One showed this train of symptoms in an adult, and Mr. Lawford afterward related a similar one in a man of 36. In all the cases primary retinitis was the ophthalmoscopic phenomenon — not papilledema. Treatment by thyroid and pituitary extracts seemed to benefit some. In later cases the anterior lobe only was used. *X*-rays could show enlargement and destruction of the sella turcica.

The president (Dr. Berry) remarked that many had no doubt observed bitemporal hemianopia due to acromegaly and asked did it begin with pituitary changes or was it owing to subsequent changes in the sella turcica—effects of pressure on the decussating fibers which ran to the ventral surface of the chiasma?

Mr. Doyne regretted that Mr. Fisher did not ascertain the field for color in his cases, he having shown the importance of this for prognosis ten years ago. Mr. Jameson Evans had watched a case of hemianopia which went on for ten years without any other symptoms, but then developed signs of pituitary growth, for which an operation was performed, without success. He treated one case with thyroid, but loss of weight ensued. Pituitary extract only increased urinary secretion. Acromegaly seemed to do well on mixed thyroid and pituitary extracts. Mr. Richard Cross attributed the cases to pressure on the chiasma. Mr. Hewkley asked if others found hyperesthesia of the remaining sensitive part of the retina? In one of his cases the patient found a street lamp very dazzling. Mr. Fisher, in reply, said only one of his cases was acromegalic. He felt sure many cases were due to enlargement or growth pressing on the chiasma. He regretted he had not investigated the color fields, but he did not think Mr. Doyne had proved that they were an absolute guide to prognosis, though it would be a great gain if it came to that.

Dr. A. E. Garrod has been studying joints by auscultation and brought his conclusions before the Medical Section of the Royal Society of Medicine on January 24. He found most noise when joints were not much affected. The knee joints were best adapted for auscultation, but the smallest were accessible. In osteoarthritis sounds would be heard before subjective symptoms appeared. Per contra noiseless joints were not necessarily normal, often contained fluid. Tuberculous joints were often silent. So were acute osteoarthritic, but not always, for many of them gave a "synovial crackle," indicating that the process was outside the joint. He named an "osteoarthritic scrunch" as a noise he considered due to fibrillation of cartilage and formation of osteophytes. With eburnation he heard friction, which one would suppose must be rather a hard rubbing on account of the solidity of eburnated bone. He heard friction, too, in inflammation of the tendon sheaths, and here I should be more disposed to agree with the term. Questions were asked about gouty joints, as to which Dr. Garrod had nothing to say. Other questions related to extraneous sounds, but he thought with practice it became easy to discriminate these.

In the same section Dr. Essex Wynter had a paper on the absence of abdominal respiratory movements as an indication of pericarditis. He did not assert that every case of pericarditis would show such absence, or even loss of such movement, but observers had to a great extent considered it only in connection with acute abdominal lesions, except, perhaps, in paralysis of the phrenic nerves. In lesions of the lung and pleura the function of the diaphragm was suspended—mostly on one side only. In acute pericarditis this was the case on both sides and in the absence of obvious abdominal disease was significant, though other symptoms, such as rigidity of muscles and tenderness, were lacking. The inertness of the diaphragm was not merely inferred; it could be demonstrated by *x*-rays.

Some differences of opinion were expressed as

to the frequency of the symptom, although it was admitted that it might often be noticed. Dr. Percy Kidd had seen the abdomen motionless in some cases. So had Dr. N. Raw, and with the recti muscles also tense. Dr. Cassidy had known two cases to be diagnosed as abdominal which proved to be pericarditis. Dr. R. Hutchinson said the loss of movement could not be seen in all cases; perhaps it was most noticed when the pericardial diaphragmatic surface was affected. This suggestion seemed probable to Dr. Voelcker. Dr. John Fawcett said caution was necessary in early cases in which some were suffering from pneumococcal peritonitis, and the advent of peritonitis was a sign of further infection. Sir John Broadbent had seen a case in which slight movement in the lower part of the abdomen took place on a deep inspiration. Dr. Mitchell Bruce (president) said that in genuine abdominal cases the inflammation might spread hrough the diaphragm to the pericardium.

Dr. Wilfred Grenfell, C.M.G., of the Labrador Royal National Mission to Deep Sea Fishermen, is now here and has given some account of the terrible sufferings the party endured, as well as some of the results attained. The mineral possibilities and pulp values are attracting attention, but the fisheries are declining. The Eskimo, too, seem to be degenerating. The Moravians have been laboring among them for many years and have done as good work as in Greenland, but they seem to be losing their nomadic habits, and when they settle down in permanent huts they become indescribably filthy, though when they move about some degree of cleanliness is insured. Epidemics have been imported and hundreds have perished. A form of typhoid resembling typhus prevailed, but tuberculosis seemed the most fatal disease. Dr. Grenfell is starting a campaign to fight it with a surgeon and nurse to begin next season, and says the amount of medical work to be done is very great. He often persuaded Eskimos to destroy their huts on account of their extremely unsanitary condition. Beriberi had attacked their stations, but not to a very great extent. Appendicitis was not uncommon. He heard of no such thing as nervous prostration among the Eskimos, whom he describes as fine physical men, brave, simple, stable, and naturally religious. The mission is now building a home for the fishermen on the lines of Rowton Houses, also a new steamer for conveying stores between the several stations. If I had space to describe the hardships and risks faced by the several doctors you would not wonder that last year one of them was nearly played out, and Dr. Grenfell himself hardly escaped with life more than once.

The British Government, at the request of that of China, is sending a medical expert to assist in revising measures against the plague in Manchuria. Dr. Reginald Farrar, who was on plague and famine duty in India, 1899-1900, has been selected for this work.

Dr. Seymour Taylor ought to hear some of the comments of general practitioners respecting a speech he made at the spectacle company's dinner. He seemed to think it quite right for these tradesmen to examine patients and prescribe corrections for errors of refraction. So another branch would be set up at the expense of medical men. I will not quote the sayings of some of those who are thus to be robbed.

The first Lannelongue prize has been awarded to Sir Victor Horsley.

The new building of the Royal Society of Medicine is to be a story higher than at first intended, it having been agreed to erect a fourth.

OUR CANADIAN LETTER.

(From Our Special Correspondent.)

MEDICAL RECIPROCITY BETWEEN QUEBEC AND THE OTHER PROVINCES OF CANADA—TEETH OF TORONTO SCHOOL CHILDREN—SCARLET FEVER IN TORONTO—REPORT OF TORONTO GENERAL HOSPITAL FOR 1910—NEW BOARD OF HEALTH FOR ONTARIO—WATER SUPPLY OF OTTAWA—VITAL STATISTICS OF TORONTO FOR 1910—PURE MILK ACT FOR ONTARIO—CIVIC CHARITY IN TORONTO IN 1910—JOURNAL OF THE CANADIAN MEDICAL ASSOCIATION—RECIPROCITY BETWEEN M'GILL AND TORONTO UNIVERSITIES—QUEEN'S UNIVERSITY AND THE CARNEGIE REPORT—THE MEDICAL OFFICER OF HEALTH OF MONTREAL RETAINS HIS POSITION—THE USE OF WHITE PHOSPHORUS TO BE PROHIBITED IN CANADA—MEDICAL INSPECTION OF SCHOOLS IN TORONTO.

Toronto, February 15, 1911.

A BILL is to be presented to the Canadian Legislature by means of which an endeavor will be made to place medical men in the various provinces of the Dominion on an equal footing provided that these provinces accept medical certificates issued in Quebec. At the present time medical certificates properly registered in the United Kingdom are recognized in Quebec, but like certificates from Ontario or from the United States are not accepted. The bill has been drafted with the approval of the College of Physicians and Surgeons of Quebec. The Dental Educational Committee of Toronto have recently submitted to the management committee of the Board of Education a report which shows that the state of the children's teeth in the two schools chosen for inspection is deplorable. The most serious features of the report are as follows: That a very large percentage of the pupils in both schools could not make full use of their powers of mastication because of decayed and defective teeth. That 99 per cent. of the pupils in one of these schools were found to have pus exuding into the mouth, the same being swallowed with their food. That 29 per cent. of the pupils attending one of the schools were in need of dental treatment. There has been a considerable amount of scarlet fever in Toronto. In January, according to the Medical Officer of Health, there had been more cases among adults than for the past ten years. The medical officer ascribed the unusual prevalence of the disease to the arrival in Toronto of outsiders from places where it is not so prevalent as in Toronto. According to the annual statement of the Toronto General Hospital there has been an increase of 400 patients suffering from typhoid fever treated there during 1910. The figures for 1910 are 304 cases and 32 deaths, compared with 242 cases and 13 deaths in 1909. There has also been a large increase of insane patients, the number being 50 cases in 1910 to 15 in 1909. Cases of appendicitis have also been on the increase, there having been 200 cases last year to 258 in the previous year. Tubercular cases decreased in 1910, there having been 180 as compared with 188 in 1909. Malignant diseases likewise showed a decrease. However, the general mortality at the hospital has been small while, although anesthetics were administered on 2,250 occasions, no fatalities occurred. By an order in Council recently passed

the government of Ontario has appointed Dr. Adam Wright of Toronto chairman of the new provincial board of health. His colleagues are Dr. David B. Bentley of Sarnia, Dr. G. Clinton of Belleville, Dr. W. H. Howey of Sudbury, Dr. Paul J. Maloney of Cornwall, Dr. James Roberts of Hamilton, and Dr. J. W. S. McCullough, who has been reappointed secretary and chief health officer of the province.

After an investigation by an Ottawa civic deputation of the hypochlorite treatment of the Montreal city water supply, steps have been taken to commence purification of the Ottawa water supply by similar methods. Toward the end of January there were nearly seventy cases of typhoid fever in Ottawa, most of which are said to have been due to contamination of the water by sewage. Eight thousand, nine hundred and eight children were born in Toronto in 1910. There was a considerable increase in the number of marriages and a small increase in the number of deaths. It is stated that a bill is about to be introduced into the Ontario Legislature which will give effect to the recommendations of the Ontario Milk Commission of 1909. Among the provisions of the proposed bill there is to be one that no milk shall be sold in cities of over 50,000 population except in bottles or in other sealed packages. It is said to be also probable that pasteurization carried out under proper scientific regulations will be demanded and that all milk offered for sale shall have at least 12 per cent. solids.

The Toronto city relief officer in his annual report shows that during the year 1910 there were 2,666 applications for relief and for hospital attendance, the figures for 1909 being 2,651. The applicants for hospital admission made up 1,756 of these cases in 1910 and 1,558 in 1909. The first number of the *Journal of the Canadian Medical Association* was issued in January. This is the official journal of the Canadian Medical Association and the *Montreal Medical Journal* is merged in the new publication. Dr. Andrew MacPhail, who has for several years edited the latter journal, has been appointed editor of the *Journal of the Canadian Medical Association*. The first number contains many original articles and a very generous supply of editorial matter. Its composition both in quantity and quality reflects credit on the contributors and great credit on its editor. At the present time reciprocity seems to be in the air of Canada, not only in commercial but in medical affairs. An agreement has been arrived at recently by the medical faculties of McGill and Toronto Universities. By this agreement the examinations of one university are accepted by the other up to and including the examinations at the end of the fourth year of the five years' curriculum. According to the *Journal of the Canadian Medical Association* for January, "The agreement provides that any student who leaves either institution with a clean bill of health, academic and moral, shall be accorded without further examination the same standing that he had in the faculty he left."

The Carnegie report on the medical schools of the United States and Canada has certainly stirred up a hornet's nest. Among the schools of the two countries upon which severe strictures were passed was that of Queen's University, Kingston, Ont. In a publication issued by the medical faculty of the university in December the report in its turn is subjected to acute criticism. The faculty strongly dissents from the view promulgated by the report and which held up the medical school of Queen's University to a certain degree of obloquy. The argument is that the inspection was too cursory to be of real value. It is stated that the inspection of Queen's University by Mr. Flexner and Dr. Colwell occupied only a part of an afternoon. The publication of the medical faculty defends the points raised in the Carnegie report in detail. An attempt has been made to dismiss Dr. Louis Laberge, who has been for many years medical officer of health for Montreal on account of his affiliation with a Masonic lodge. Dr. Laberge is a Roman Catholic and many of his coreligionists resented the fact that he was a Mason. The Board of Control of Montreal had made the usual recommendation that Dr. Laberge be reelected to his post for a year, but several French Canadian Catholics objected. Eventually a motion was brought forward to dismiss Dr. Laberge, but was defeated by a majority of the City Council, every English speaking member of the Council voting against it. The Canadian House of Commons has adopted the principle of the Hon. Mackenzie King's bill to prohibit the manufacture and importation of matches made from white phosphorus. The bill was objected to by some on the grounds that its enforcement would enrich the United States "match trust," as Canadians would have to pay more for the use of the patent process. The Board of Education of Toronto has decided, at last, on a complete and comprehensive system of medical inspection for the schools. Dr. W. E. Struthers has been appointed chief medical inspector. An attempt was made to have the medical inspection department placed under the control of the Board of Health, but without success. The department will be composed as follows: One chief medical inspector at $2,500 a year, eight assistant medical inspectors at $800 a year each, one superintendent of nurses at $1,800 a year, seventeen school nurses at $600 a year each, one clerk at $600. Dental inspection, $1,200.

OUR LETTER FROM THE PHILIPPINES.

(From Our Regular Correspondent.)

INTESTINAL PARASITES—OFFICERS OF MANILA MEDICAL SOCIETY—CHOLERA OUTLOOK—ANTIVACCINATION—BREEDING FLIES IN MANILA—FAILURE OF CANCER VACCINE—PERSONAL.

MANILA, P. I., January 10, 1911.

THE regular monthly meeting of the Manila Medical Society was held last evening at 8.30 at the Philippine General Hospital. A paper was read by Dr. Willets, Assistant Professor of Medical Zoölogy, College of Medicine and Surgery of the University of the Philippines, entitled "The Statistical Study of Intestinal Parasites in the Tobacco Haciendas of the Cagayan Valley, Philippine Islands." Dr. Willets reported that he had done this work in connection with the study which was being made by the Bureau of Health for the purpose of determining the percentage of intestinal parasite infections among the general population of the Philippines. He stated that in all approximately 19,000 persons were examined and that among the first 4,000 were the prisoners at Bilibid, 84 per cent. of whom were found to be infected with some form of intestinal parasite and 52 per cent. had hookworms. The next extensive examination was made at Taytay in which 1,000 persons were examined;

95.90 per cent. had intestinal parasites in some form and 10 per cent. had hookworms. The next examination was made at Las Piñas in Rizal Province where 6,000 persons were examined, of whom 90 per cent. harbored some form of parasite and 16 per cent. had hookworms. After that it was deemed advisable to make a certain number of examinations in inland towns where the influence of the sea would not be felt and accordingly 2,594 examinations were made at Tuguegarao in the Cagayan Valley; here 74.13 per cent. were infected and 8.01 were found to have hookworms. The next examination was made at a large tobacco ranch named Santa Isabel, at which 802 persons were examined, and 86.28 were found to be infected with some form of intestinal parasite and 45.38 had hookworm. The next extensive work was done on the Hacienda San Antonio, which is probably the largest tobacco ranch in the Philippine Islands; here 4,278 persons were examined and 85.40 per cent. infected with an intestinal parasite in some form and 54 per cent. had hookworms. This examination was made at the special request of the owners of the plantation, who reported that their laborers were apparently more indolent than is generally the case in the Philippine Islands.

From the foregoing it will be apparent that with the exception of the examinations made at Bilibid and those of the Haciendas Santa Isabel and San Antonio, the average percentage of hookworm infections is about 12 per cent. Dr. Willets was of the opinion that the work so far done showed that the intestinal parasites had a most important influence on the mortality and morbidity of the Philippines.

The following officers of the Manila Medical Society for the ensuing year were elected: *President,* Major Weston P. Chamberlain of the U. S. Army Medical Corps; *Vice-President,* Dr. R. E. L. Newberne; *Editor of the Bulletin of the Manila Medical Society,* Dr. W. E. Musgrave; *Acting Editor,* V. L. Andrews; *Secretary and Associate Editor,* Dr. F. W. Bowman; *Treasurer and Business Manager,* H. D. Kneedler; *Councilors,* Dr. W. E. Musgrave for four years and Dr. V. L. Andrews for five years.

The cholera outlook in the Philippines is more encouraging at this writing than it has been for the past seven years. So far as known the disease exists now only in Naujan, Mindoro, and on the Island of Catanduanes, which is on the east coast of Luzon opposite Albay Province. There are, however, almost daily reports of suspicious cases from many of the provinces, but upon more careful clinical examination these cases so far have been finally diagnosed as negative for cholera. It is unfortunate that the facilities of the Government do not permit of thorough laboratory examinations being made of the inhabitants of communities from which such cases are reported in order to determine whether cholera organisms are present in the stools of suspected cases or whether cholera carriers are present. It would seem reasonable to infer that cholera might be kept alive between epidemics in this manner.

The difficulties under which some of the vaccinators of the Philippine Islands labor is well shown by a recent report which has been received from Capiz province. Smallpox has prevailed in that province for a great many years in spite of the extensive vaccinations which were reported to have been done. One vaccination party after another has been sent into that section, but it seemed to be impossible to eradicate the infection completely. A more thorough study of this matter shows that a fair percentage of the population in the more remote districts is opposed to vaccination and almost invariably fled upon the approach of the vaccinators so that there are still large numbers of unvaccinated persons. Public feeling against vaccination in such localities runs very high and in many instances vaccinators have been unable even to buy the necessary food with which to sustain life. Under these circumstances it is indeed not surprising that vaccinators fail to perform their duties faithfully. A study of the cases and deaths which have occurred during the past six months shows that no death has occurred in a successfully vaccinated person.

The value of modern sanitation was recently very well shown in the experience had in Manila. The parking of the new Luneta, the grounds of the new Elks Club and the Army and Navy Club, and the new Philippine General Hospital required large quantities of manure for fertilizing purposes. In order to hasten fermentation as much as possible this manure was used without being treated with lime or kerosene and therefore furnished an excellent breeding medium for flies. These bred in enormous numbers with the result that the Bureau of Health has received a veritable storm of complaints against the nuisance created by the flies. Ordinarily flies are very rare in Manila, which is probably due to the daily collection of garbage and street sweepings and the proper disposal of the same.

Several of the cases of cancer that were treated about a year ago with cancer vaccine after the method of Gilman and Coca and which were apparently cured have relapsed. Extensive metastases have occurred.

Captain Horace D. Bloombergh of the U. S. Army Medical Corps, who has been a member of the Army Board for the Study of Tropical Diseases, has completed his term of duty in the Philippines and will return to the United States upon the transport which leaves here February 14.

The Examination of the Nose and Throat in Relation to General Diagnosis. Results in Asthma Following Nasal Operation. H. Z. Giffin.

Neurological Hospitals.—P. Bailey states that to meet the task set before him the neurologist must have for the field of his activities some central workshop where he can study his patients, communicate freely with those who work with him, carry out his experiments, and impart to others his methods of work and the results of his experience. An institution of this kind should be divided into a city plant and a country plant. The former should be in the nature of a reception hospital for the purposes of diagnosis, surgical treatment, for the treatment of cases that are likely to be of short duration, and for the care of patients with wrong ideas about their health, who should be kept long enough to counteract improper psychical influences and erroneous theories on physiology. The country plant or sanatorium should be fitted up for the care of chronic and charity cases and those not suitable for the city plant. This includes those

who are crippled and those for whom outdoor life and occupations are indicated. The mental cases must be provided for chiefly in the country.

Neurological Service at Boston City Hospital.—P. C. Knapp in reviewing the first year's work of this service notes the remarkably small proportion of cases suffering from the various neuroses—less than one-seventh of the total number admitted. He believes that very many cases of neurasthenia and psychasthenia do better if they can be in the world and can do certain work therein under wise counsel than they would do within the walls and under the deadening routine of an institution.

The Youthful Psychopath.—J. W. Courtney states that from his own personal experience and observation he is convinced that psychasthenia, hysteria, paranoia, and dementia precox are identical in pathology and that in the overwhelming majority of cases they are hereditary in origin and slow in evolution. He is furthermore convinced that unequivocal clinical signs of their presence are always observable as early as the fifth year of life—in certain cases even earlier; and it is to the victims of these manifestations that he has applied the not altogether satisfactory term—"youthful psychopath."

Tumors of the Bladder.—L. Davis states that clinical evidence seems to support the theory of malignant transition of originally benign papillomata. There is a very marked tendency for papillomata to recur. These growths often reappear not upon the original sites, but at other points on the bladder wall, springing up *de novo* as it seems, in response to a general predisposition to the disease which is unaffected by the removal of any one growth. As a rule, rapidly and repeatedly recurring tumors are malignant in the end, if not from the beginning. That every recurrent papillary growth is malignant is far from true, however.

Operations for Tumors of the Bladder.—C. L. Scudder concludes, with regard to the surgical treatment of tumors of the bladder, that certain of the small apparently benign papillomata may be safely removed by the suprapubic method, but should be removed even with this approach by a good margin of excised, healthy tissue. The transperitoneal approach to the bladder will enable the surgeon to successfully attack cases of malignant tumor of the bladder which, without this approach, might be forced to a more dangerous extraperitoneal cystectomy. Watson's proposed cystectomy and double nephrostomy should be employed only when a partial cystectomy done transperitoneally is inapplicable. The transperitoneal approach to the bladder will care for many cases that otherwise would have to be treated by Watson's method of cystectomy. Tronsperitoneal cystotomy is a procedure that has come to stay. Its employment should lower the percentage of recurrences in tumors of the bladder of all grades of malignancy.

Intravesical Operations for Bladder Tumors.—H. Binney states that the results of the reported intravesical operations, numbering something over 200 cases, may be summarized as follows: Mortality, ½ of 1 per cent. or less, there being but one fatal case in the whole number; hemorrhage, severe enough to require control by suprapublic cystotomy, in three cases; cure for at least three years has been established by cystoscopic examination in 50 per cent. of the cases reported by Weinrich. The exact percentage of cures cannot be figured at present, owing to the failure of the operators to confirm an apparent cure by cystoscope. For this same reason the frequency of recurrence after the intravesical operation cannot be estimated from the reports. In the original statistics of Nitze the recurrences are given as 18 per cent., which is better than the figure stated by Rafin in his collected statistics of suprapubic operations, which was 26 per cent. In conclusion, it is stated that the published results of intravesical operations do not at present warrant the adoption of the method for the removal of primary growths except in cases of very small tumors or in patients in whom a suprapubic cystotomy under an anesthetic is contraindicated. In cases of repeated recurrences after suprapubic operations the method is to be recommended over the performance of frequent suprapubic operations.

Nose and Throat in General Diagnosis.—H. Z. Giffin notes that the patient's general condition affects the mucous membrane of the nose and throat and that abnormal nasal conditions affect the general health. The affections of the nose and throat are not being carefully considered by general practitioners. Acute headaches with fever, no matter to what part of the head the pain may be referred, are often due to sinusitis. Dull, heavy headaches of a more constant and chronic type, sometimes confined to one side of the head, are often due to nasal obstruction or sinusitis. Periodical headaches are generally of nervous origin. The association of headache or nasal obstruction with the onset of the patient's complaint, particularly if the complaint be a periodical one, makes us suspect nasal disorder. The effect of chronic fibroid tonsils upon the recurrence of articular rheumatism and other disease of the rheumatic cycle should be considered. Suppuration in the antrum is sometimes at the basis of certain obscure cases of anemia. Tumors of the face and neck, including goiter, should have nose and throat examinations for diagnostic purposes. Irritative cough, especially night cough, may be entirely a reflex matter, and sinusitis may be found. Certain forms of asthma are apparently influenced by nasal conditions. In sixty-six cases of asthma that were operated upon at St. Mary's Hospital, Rochester, during 1909, definite improvement followed in 57 per cent. and cure in about 10 per cent. On tabulating the results one finds that, in general, when the attacks become less frequent they also become less severe. The general health had improved in 33 of the 52 patients. Headache had become a symptom in 31 cases and had improved in 24. Mild stomach symptoms were elicited in 25 and had improved in 20. Of the operations upon the 5 patients who were "cured," 4 were turbinectomies and 1 the removal of polyps. Improvement followed in 3 of the 4 cases in children in which adenoids and tonsils were removed. The most unusual things will occasionally cure asthma. Looking upon the condition as a spasmodic neurosis, one would, however, expect strange cures. In reality one should not strive for cures only, but should be satisfied with any procedure which will cause improvement in the majority of cases. Nasal operation seems to do this if the patients are properly selected. And there would seem to be good logic in freeing the respiratory tract of anything which might cause reflex irritation.

The Origin of Cancer and Its Control. W. McDowell.

Neurasthenia and Acute Insanity.—C. P. Noble presents a new theory as to the nature of acute functional insanity. This is attributed to the degeneration of the units or elements, of which the protoplasm of the cells of the gray matter of the brain is composed; or else the same is true of the protoplasm of the cells in the pituitary ganglion; or it is true of both. The objective evidence of the truth of this theory is to be found in the fact that

these cells in an insane individual stain differently from the cells of normal individuals. When one violates the laws of health—by unreasonable thought, leading to unreasonable acts, by selfish motives, by unreasonable hours of labor, by the failure to secure a sufficient amount of sleep, by the failure to secure reasonable recreation, and more especially by hurrying at work, and by an unreasonable attitude toward one's work—which is called the worry habit—there result exaltation of the will and increase in the production of, first, pituitary extract, and then of thyroid extract, which leads to increased liberation of nerve force in the cortex cells, also of increased metabolism in the body—hence it necessarily follows that the production of fatigue toxins is increased. This means that if the bad habits, previously related, are continued from day to day, and from week to week, chronic toxemia and chronic hyperthyroidism and the supersecretion of pituitary extract result. This constitutes the pathology of neurasthenia.

Twilight Talks with the Doctor.—G. F. Butler emphasizes the importance of optimism in the practice of medicine. The most extensive of all the morbid conditions which reflect themselves so disastrously on the human system is the state of fear. It has many degrees of gradations, from the state of extreme alarm, fright, or terror down to the slightest shade of apprehension of impending evil. But all along the line it is the same thing—a paralyzing impression upon the centers of life which can produce, through the agency of the nervous system, a vast variety of morbid symptoms in every tissue of the body.

Phrenology.—J. Knott states that there are few names whose owners have been so thoroughly misunderstood or misrepresented as has Franz Joseph Gall, the founder of phrenology.

Subphrenic Abscess.—H. Roth concludes that a subphrenic abscess is, in the great majority of cases, secondary to a perforation or inflammation of some intraabdominal organ; occasionally it results from injuries of the thorax or upper abdomen and very rarely from a primary infection of the subphrenic space. The abscess may be extraperitoneal, but the majority are intraperitoneal. More than half of the subphrenic abscesses secondary to appendicitis are intraperitoneal. A subphrenic abscess secondary to perforation of a gastric ulcer usually occurs on the left side of the suspensory ligament, while an abscess secondary to lesions of the liver or appendix is usually on the right side. The most important routes by which infection spreads to the subphrenic space are the lymphatics and blood-vessels, the subperitoneal tissue, and the peritoneum. Gas is found in about 25 per cent. of the cases, and of the bacteria present in the pus, the *Bacillus coli communis*, the streptococcus, and staphylococcus are the most important. The complications of subphrenic abscess are principally thoracic, namely, pleurisy with effusion, empyema, pneumonia, abscess of the lung, and pericarditis. The onset of subphrenic abscess may be either acute or insidious. Rapid loss of weight and strength with a high temperature, remittent or intermittent in character, may be the only symptoms present. Physical signs develop late and vary according to the presence or absence of gas with the pus. These are at times very characteristic and may enable one to make a correct diagnosis. Exploratory puncture of the chest is of the utmost importance. It may be the only means by which a diagnosis can be made before operation. In making a diagnosis of subphrenic abscess, a history of a preceding intraabdominal or pelvic disease is very valuable. If all other diagnostic means fail exploratory incision should be resorted to. Most patients who are not operated upon die from sepsis or sudden perforation into the pleura, pericardium, or peritoneum. The mortality can be reduced only by early diagnosis and appropriate treatment. The proper treatment is by incision and drainage, the site of the incision depending upon the location of the abscess. If the abscess is low down in the epigastric or hypochondriac regions it is most readily reached through an incision in the median line or one below and parallel with the costal margin. Retroperitoneal abscesses can be opened through a lumbar incision. An abscess higher up in the chest is best treated by transpleurodiaphragmatic thoracotomy, or, better still, by Elsberg's subpleurodiaphragmatic thoracotomy. Occasionally a combination of these methods is necessary.

Intestinal Putrefaction and Neuralgia.—J. Funke concludes that a limited number of cases of neuralgia are due to putrefaction products, that these neuralgias are not due to the indican, that the mere presence of indican does not signify that a disease exists, and that it is only when the precursors of this substance are not oxidized to indican that disease results. Before one can draw any conclusion as to the relationship between potassium salts and neuralgia he believes a good deal more experimental work must be carried out.

Postdiphtheritic Paralysis of Accommodation.—J. Clothier states that the eye may be and frequently is the seat of a postdiphtheritic lesion, which occurs usually in the form of a partial or complete paralysis of either the intrinsic or extrinsic muscles. The favorite seat of the lesion is the ciliary muscle which controls the accommodative apparatus, and paralysis of the accommodation is after paralysis of the velum palati, probably the most common of the various palsies that follow an attack of diphtheria. It is, furthermore, a condition that may be readily overlooked, especially in its incomplete form, for the external appearance of the eye tells one nothing as a rule, and the loss of vision which the patient may complain of may be looked upon as due to a weakness of the accommodation that may follow any wasting disease.

Technique for Preparing Salvarsan.—A. J. Hart describes his method of preparing salvarsan in oily suspension. It is claimed that the advantages of this method are that every bit of salvarsan is utilized. The syringe used to administer the drug being used also as the triturating graduate allows of accurate measurement and therefore accurate dosage. The small number of sterilized parts, *i.e.*, the syringe and a stirring rod, insures perfect sterilization. A minimum amount of exposure of salvarsan to the air is obtained.

Origin of Cancer.—W. McDowell believes that the cause of cancer is excess of food constituents in the blood, which dominate anabolism of epithelial cells; this obviously implies deficiency of (or interference with) elements which would promote catabolism of epithelium.

Teeth and Facial Development.—F. B. Noyes discusses the growth of bone as affected by the teeth, and the relations of the latter to the development of the jaws and face. The bone is produced in response to mechanical stimuli furnished by the growth of organs inclosed in or surrounded by the bone as the most important factor. Abnormal conditions may affect the formation of the jaws and face. If the occlusion of the teeth is normal the forces are perfectly balanced and a harmonious and symmetrical development is the result. In proportion as the occlusion deviates from the normal, there is a disturbance of the harmony of development. The preservation of normal occlusion, therefore, is necessary not only for the proper mastication of food but for the proper development of the face and a normal function of respiration and swallowing.

Electric Resuscitation.—L. G. Robinowitch discusses the subject of resuscitation by electricity in cases of apparent death from anesthetics and electricity. The method of resuscitation consists in causing artificial blood-pressure and respirations by means of rhythmic electric excitations until normal function is restored. The electric current of choice is a direct current, interrupted from 6,000 to 8,000 times a minute, period 1/10. Next in value is a direct current interrupted from 25,000 to 40,000 times a minute with her triple interrupter. If these two cannot be had an induction current obtained with her special model of induction coil, the special feature of which is the diameter of the wire, 1.2 mm. for the primary and 0.6 mm. for the secondary coil. In cases of grave forms of apparent death, currents supplied by coils with fine wire will kill the animal if not already dead. The physiologic effects of anodal and cathodal stimulation are different; the former are especially dangerous in the pulmonary and cardiac area when the current is obtained from a secondary coil, the wire of which is finer than 0.6 mm. Alternating and direct currents are deadly to cellular life, especially during apparent death, but if nothing else can be had rhythmic excitations may be used with these currents rather than make no effort to save life.

Ventrosuspension of the Uterus.—By D. T. Gilliam. See MEDICAL RECORD, Vol. 77, page 1075.

Surgery of Retroversion of the Uterus.—By E. C. Dudley. Se MEDICAL RECORD, Vol. 77, page 1075.

Lunatics and Habeas Corpus.—F. A. Fenning points out the abuse of privilege in the obtaining of this writ by lunatics and those acting in behalf of such persons. In so far as applies to the issuance of the writ in cases of lunatics, he argues for a limitation of such use. It must be realized that the lunatics applying for discharge by habeas corpus are in nearly every case adjudged lunatics. They are not suspected individuals who have been summarily confined, but are those who have had their day in court and have been found, in orderly manner by competent tribunals, to be in need of treatment for mental disease.

Sodium Cacodylate.—H. J. Nichols gives the results of the application to sodium cacodylate of the experiments which demonstrated the destructive action of salvarsan on the spirochete of syphilis. They consist, first, of the determination of the tolerated dose of a given substance in a normal rabbit, and, second, of the determination of the curative dose for rabbits infected with *Spirocheta pallida*. The results are expressed in the form of a ratio, C.T. The interest excited in this country by Murphy's observations with sodium cacodylate have caused others to employ it, and the results have not been uniform. The experiments are reported and the results show that sodium cacodylate has no spirillicidal action on infected rabbits in doses short of seriously injuring or killing the animals. Of course, facts gained by experiments on animals cannot be transferred directly to human medicine, but much of the knowledge of salvarsan has been obtained in that way. Dawes and Jackson have shown that the therapeutic effect of sodium cacodylate is really due to decomposition and reduction products, such as cacodyl, arsenious and arsenic acids. The amount of reduction depends largely on personal idiosyncrasy and this introduces a very uncertain element. For all practical purposes salvarsan should be regarded not as an arsenical compound but as a new substance not specifically related to ordinary arsenic. While there is no indication from experimental evidence for the use of sodium cacodylate in syphilis, it does not interfere, as has been suspected, with the action of salvarsan used subsequently. At present it may be taken for granted that salvarsan is a specific against syphilis, and the important question now is, what is the best dose and what is the best method of its administration in a given stage of the disease? There is considerable evidence to show that the size of the dose should vary inversely with the duration of the disease. Alt's original method of injecting intramuscularly seems to hold its own for certainty of results. The Wechselmann method has been somewhat discredited by the slow absorption and liability to necrosis of tissue. A single intravenous injection in some cases seems to be too brief in action, but further experience is needed on all these points.

Experimental Poliomyelitis.—R. B. Osgood and W. P. Lucas report experiments made in the transmission of the virus of poliomyelitis from the nasal mucosa of paralyzed monkeys after the acute stage had passed to other monkeys. These show that it is possible to transmit from monkey to monkey a typical poliomyelitis from the filtrate of the nasopharyngeal mucosa of two monkeys dying without other discoverable infections, respectively, six weeks and five and a half months after the acute stage of the disease. In one case they were able to transmit the disease from the nasopharyngeal mucosa of a monkey dying in the acute stage. They were unable to transmit the disease from monkey to monkey by intercerebral inoculations of the cord and brain of these recovered subjects or from filtrates of the nasopharyngeal mucosa of a monkey in apparent good health which had received a previous intracerebral inoculation of an active virus with only questionable prodromal symptoms, but which had lived in closest contact with monkeys in the acute stage of the disease. They have noted no case of transmission from monkey to monkey except by direct inoculation, though the animals were exposed both by contact and the use of the same feeding utensils.

The Stomach in Diabetes.—J. J. Gilbride reports the results of tests of the gastric contents in seven diabetics. It has been known for some time that the gastric motility has usually been increased in diabetes while the gastric secretion is frequently diminished. The object of the study was to test the secretion of pepsin, and eighteen tests were made, of which detailed accounts are given. The total acidity and amount of free hydrochloric acid were determined and tests were made for lactic acid when hydrochloric acid was absent. No lactic acid was found. The total acidity was high in three cases and free hydrochloric acid was high in four. Hydrochloric acid was absent in three. The tests show that this absence in diabetes mellitus, as in other diseases, does not mean an absence of pepsin, and a high percentage of the acid does not indicate a good pepsin digestion. While general conclusions are not deducible from these few cases, it may be said that the pepsin secretion is frequently reduced and sometimes absent in this disease, and this may be added to the other

well-known fact mentioned in the beginning of the article, viz., that the motility of the stomach is increased, together with the frequent diminution of the gastric secretion.

Nitrous Oxide Anesthesia.—R. C. Coburn points out the advantages of the use of the nitrous-oxide-oxygen combination for general anesthesia in preference to the usual anesthetics employed. It is a mistake to think that it is better adapted for minor surgery and short operations than for major work, for the longer this anesthesia is maintained the better it becomes in every way. The author has used it in difficult and complicated operations lasting over four hours, and he quotes the testimony of other surgeons to the same effect. The destructive action of ether and chloroform on the blood and the consequent greater liability to infection by destruction of leucocytes are noticed as well as the irritant effect of ether on the organs of respiration. It is the remote effects of these other anesthetics that seem most to be avoided. With nitrous-oxide-oxygen these are absent and he assents to the statement of Gatch that very ill patients with rapid pulse and quick shallow respiration actually seem benefited by this form of anesthesia. He quotes the testimony of a patient that anesthesia by this method was like a pleasant dream as showing how much it describes the discomfort to the patient.

Gastric Sarcoma.—O. W. H. Mitchell reports a case of sarcoma of the pylorus in an aged woman. The diagnosis was carcinoma, and at the autopsy a firm annular tumor, five inches in diameter, was found involving the pyloric end of the stomach. There was no evidence of metastatic growths and the patient did not look especially cancerous, but microscopic examination showed the tumor to be a small round-cell sarcoma.

Administration of Salvarsan.—D. W. Montgomery states that one-third by weight of salvarsan is arsenic. Therefore in administering 0.6 gram, the ordinary dose, one is giving the patient 0.2 gram of arsenic or many times the toxic dose in ordinary pharmaceutical preparations. Great care should, therefore, be observed in giving it. It is put up as a dry powder in glass tubes, and in this form seems to be stable. In solution, however, it quickly decomposes, especially if the solution is alkaline. It is given suspended in oil or as a solution and must be made up fresh each time. The author has never seen it given in oil, but it has been so given by Neisser, who recommends oil of sesame. The acid watery solution is very painful when injected and should be made either alkaline or neutral. The trouble and care required have induced various modifications of the technique, but the author has seen the best results by comparatively simple methods. If Ehrlich's ideas as to the sterilization of the body are correct, the intravenous method is the only correct one, and it has the further advantage of being painless. Montgomery gives in full detail the technique for the preparation of the solution for intravenous injection and the technique of the method as carried out by Schreiber of Magdeburg, following more closely that of the latter. He specially emphasizes the importance of having the solution perfectly clear with no undissolved particles, the assurance of the fact that the needle is in the vein, and the importance of the injection of a small quantity of normal salt solution just before and after the salvarsan injection. The injection should be slow, taking five or six minutes, so as to avoid sudden overloading of the circulation. All instruments should be most carefully sterilized and cork stoppers should be avoided and glass ones used instead. If it is desired to neutralize the fluid for injection after it has been made alkaline it is best done by adding, drop by drop, a 1 per cent. glacial acetic acid solution, testing the neutral point by letting a drop of the fluid fall from the tip of a glass rod on litmus paper.

Treatment of Drug Addiction.—A. Lambert states that his later experience has confirmed his former views. He has endeavored to simplify the method, however, and has succeeded in some measure, and he repeats the details of the treatment as modified. The belladonna mixture of 2 parts tincture of belladonna, 15 per cent., and 1 part each of the fluid extracts of hyoscyamus and xanthoxylum is essential in the treatment and seems to have some special properties rendering it useful in combating the desire for the drug. The bottle containing the mixture must be kept well corked and should be shaken before using. The active purgation described in his former article is also employed in his modified treatment. He finds the morphinists generally desirous of getting rid of their habit, and with them the cure is generally permanent. With the alcoholics the case is different. The social temptations are a constant danger and total abstinence the only safety. In spite of this, however, the treatment is the best he knows of for eradicating the desire for alcohol.

Salvarsan.—O. S. Ormsby reports his experience with salvarsan in eight cases under observation for more than three months. The most striking results were obtained in a patient with deep gummatous and ulcerative lesions involving bones and deep structures. In none of the cases could a positive cure be claimed. The series emphasizes the facts shown by others, which are summarized as follows: Recurrences and recrudescences commonly happen after a single injection, which indicates repeated injections or resort to older methods to complete the eradication of the disease. A marked and profound effect is immediately produced, which makes one indication clear for its use, viz., a rapidly spreading malignant case in which ulceration threatens vital or useful structures, and an immediate result is imperative. The effect in promoting increased nutrition is marked, especially in cachectic patients, thus placing the patient in a better physical condition to normally combat the invading organisms. Admitting the value of salvarsan in syphilis, the author thinks that it cannot be admitted that it replaces other treatment to any great degree. It is the consensus of opinion that its greatest value is in the malignant cases and in those which have resisted other well-known remedies.

Support for Thigh Elastic Stockings.—C. C. Johnson, to prevent these from rolling down at the top, recommends the following device: Four or five ordinary dress stays are sewed at varying intervals around the top of the stocking in the longitudinal diameter. It will be found that this ends the trouble. The author, however, suggests that the manufacturers weave small whalebone stays in the stocking in the same manner; this would make a more durable and attractive article.

Nephrolithiasis.—W. P. Willard reports a case of this condition in which there was repeated temporary relief from ureteral catheterization.

Clinical Aspects of Emotion and Action.—T. C. Shaw states that physicians in active practice are often brought face to face with cases where things go wrong in the family, where one feels sure that the conduct of one or other of the parties is giving much trouble, and yet where the plausibility of the protagonist in the difficulties and his, or her, general intelligence and conduct in other matters are such that one deems it hopeless, and indeed impossible, to prove legally that a real mental disturbance

is at the root of the trouble. There is apparently nothing wrong with what is called the intellect, the ordinary relations with friends are kept up, strangers see nothing different from usual, and yet a formerly peaceful home is made a hell through a change in one element of a mental content—namely, an alteration in feeling or emotion. Or a patient may be observed to be doing things which tend to compromise himself and to imperil his family prospects—all the while that he talks like an angel, professes the best of motives, and shows to the world around him no sign of impairment of intellect which entitles his friends to the protection of the law, and so he is allowed to pursue his career because those responsible for him are afraid of the legal consequences of trying to stop him. On the stability of emotion we build our social fabric; we shape our ends as regards individuals on the basis that their sentiments and emotional tones are the same as they ever were—not their ideas, but the emotional tone of their ideas. The benevolent man is the prey of the harpy and the extortioner; the miser is left to his niggardliness, despised and ridiculed. If the man of hitherto fixed mental trend surprises his friends by appearing in a new character, if from being a lively Autolycus he becomes a cross-gartered Malvolio, the first question asked is as to his sanity, and herein lies a great truth, the fact that change in the emotional tones is not the precursor merely of mental instability, but it is a sign that the mischief is actually there—that disease has already begun. The general practitioner as a practical psychologist, trained by experience in the school of observation, is the man in whose hands lies more than in any others the determination of the real nature of these disturbances of emotion and action, he is constantly at work in the human laboratory of causes and effects, and if to his never-ending school of phrenology he can add the analysis that training in psychology gives, one has all that is required for the proper appreciation of what man is intended to be—a machine to think and to act. It is above all things necessary in treating cases of emotional alteration to place them in new surroundings, away from family influences, to persist in methods calculated to arouse new ideas with their own peculiar emotional tones, so as to let the old ones starve by inanition—not so much to leave the individual to fight his own morbid thoughts (a process which often tends to emphasize the disordered function, because the very fact of trying to overcome it keeps strongly in consciousness the one thing which one is seeking to weaken)—not to leave the patient alone to struggle with his obsessions, but to take away ourselves the weight from him, to release him of the burden which he vainly tries to shuffle off. It is in this way that suggestion becomes a powerful agent, not by poohpoohing certain painful feelings and saying that they do not exist, but by ignoring them and setting up other strong tones, while time will aid one in subduing old influences. The patient must be kept going in new tracks, while the old footsteps are gradually made faint, not by his own scattering of oblivious sand, but by a gradual and final desuetude. This is the rationale of Freud's treatment, and it is easy to perceive how long and tedious the cure may be.

Color Vision and Color Blindness.—F. W. Edridge-Green states that in the construction of a test for color blindness the following facts are of practical importance: Most color blind make mistakes with certain colors, but are correct with regard to others. The color blind name colors in accordance with their color perception, and thus show definitely to which class they belong. Colors may be changed to the color blind while leaving them unaltered to the normal sighted. The phenomena of simultaneous and successive contrast are much more marked for the color blind than for the normal sighted. Many color blind match correctly but name the principal colors wrongly. Many color blind recognize colors easily when they are close to them or the surface is large, but fail to distinguish between them when they are at a distance or the image on the retina is small. The color blind are more dependent upon luminosity than the normal sighted, and are liable to mistake a change in luminosity for a change of color. The color blind find special difficulty with faint and dim colors. The color blind who have shortening of the red end of the spectrum cannot see reds reflecting or transmitting only rays corresponding to the shortened portion. The color blind find more difficulty in comparing colors when different materials are used than when the colored objects are all of the same nature. Most color blind find more difficulty with transmitted than with reflected light. The color blind have a defective memory for colors. Colors may be changed to the normal-sighted while leaving them unchanged to the color blind. The color blind may have a sense of luminosity similar to that of the normal sighted. The dichromic distinguish between the colors of the normal sighted which are included in one of theirs by their relative luminosity and the difference of a saturation which is apparent to them.

Injuries Caused by Electricity.—Sir Thomas Oliver describes the following treatment for those injured by electricity: For slight shock followed by recovery no treatment is required. For burns the application of boric acid compresses, or charcoal poultices if there is much destruction of tissue, is called for. Where an injured workman is in contact with, or cannot lose grip of, live metal the greatest care must be exercised in touching his body, for any attempt to separate the two might be followed by a disastrous shock to the person rendering assistance. Under any circumstances the breaking of the current means a fresh shock to the individual concerned. The rescuer should have his hands in indiarubber gloves or wrapped round with thick, dry rags. If it is a live wire with which contact has been made this should be cut if possible with long iron scissors in wooden handles. Once the circuit is broken, should there be no signs of life, the body must be placed upon its back and artificial respiration immediately resorted to and continued for a considerable time. Even if there is no quick response, artificial respiration should be continued. In the author's experiments he succeeded in resuscitating animals whose heart and respiration had ceased for several minutes, and at an inquiry concerning regulations for electric power stations one of the witnesses stated that at his works in one man who had received 2,000 volts shock the doctor pronounced life to be extinct, but his fellow workmen immediately resorted to artificial respiration, and as the result of having kept this up for over an hour the man is at work to-day.

Inoculation of Tuberculin with Local Anesthetic.—H. W. Crowe draws the following conclusions: 1. There is a distinct difference in the response to an inoculation of tuberculin in phthisis if eucaine be combined with the dose. 2. The chief proof of this rests on the form of opsonic curve which follows such doses as compared with doses in which no eucaine was given. 3. There is a possibility that an inoculation of tuberculin produces its effect in part by stimulating the central nervous system. 4. Such stimulation may take place at the site of inoculation.

Pantopon Anesthesia.—C. L. Leipoldt refers to the recent works of Burgi, who found, what was already known clinically, that two narcotics introduced simultaneously or shortly after each other have a much more powerful effect than when a total quantity of one narcotic, equivalent in strength to the combination, is administered. This triple or quadruple increase of action is greatest when the two narcotics have different cell receptors, and a dose of one drug acts much better when it is given in relatively small quantities, with an interval between each administration, than when it is exhibited at once. In the

early part of 1909 Sahli of Berne, experimenting with the various alkaloids contained in crude opium, concluded that the most effective narcotic was a definite, stable solution of these alkaloids, in which the relative strength of the various constitutents was definitely known or could be accurately measured. This, briefly, is a mixture of the soluble chlorides of opium in which the relative strengths of the following are claimed to be known: morphine, narcotine, codeine, papaverine, narceine, thebeine, hydrocotarnine, codamine, laudanine, laudanidine, laudanoeine, meconidine, papaveramine, protopine, lanthopine, cryptopine, goscopine, oxynarcodine, xanthaline, and tritopine. The ideal combination for pantopon, so far as surgical anesthesia is concerned, is with gas and oxygen as a general anesthetic. This method demands a somewhat complicated apparatus.

A New Method of Administering Nitrous Oxide.—N. S. H. Warner describes a special form of inhaler, which he calls a nasooral inhaler and which has two separate parts—a nosepiece and a mouthpiece. A metal attachment is adjusted so that two rubber tubes are in connection with the ordinary "gas bag." These tubes pass one each side of the patient's head, and are joined to a hollow metal T-piece, which rests against the forehead. The vertical or lower part of the T-piece has a wider bore and is joined to the top of the nosepiece by a short piece of rubber tubing.

The History of Yellow Fever in West Africa. Sir Rubert Boyce.

Choice of a Diuretic.—E. Smith states that digitalis is a safe and efficient promoter of diuresis, but it is not to be depended on under all circumstances. It acts by causing contraction of the peripheral blood-vessels—those of the kidney excepted—and increasing the force of the cardiac systole. But in renal disease the blood pressure is often raised already, and to raise it still more is to force an excess of work upon diseased organs. Caffeine and diuretin have an action directly upon the secreting cells of the tubules, and indirectly on the renal vessels, which in some measure they dilate. But in acute renal dropsy when the cells are more or less seriously diseased the use of these remedies is calculated to lessen secretion instead of to augment it and is apt to be productive of harm. The saline diuretics, the citrates, acetates, and tartrates of soda, potassium and ammonia increase the osmotic pressure of the blood and draw water from the tissues into the blood stream. They do not irritate the kidneys and may be used without fear—even when the organs are acutely inflamed. By the use of the hot air bath, or the hot pack, the activity of the skin is promoted and the kidneys are relieved of part of their work. The sparing use of protein in the food relieves the overburdened kidneys. The beneficial results which sometimes seem to ensue from an exclusive milk diet are not improbably dependent upon moderation in the quantity prescribed, a liking by the patient himself for this form of nourishment, and the greatly reduced intake by this means of common salt, for milk contains no more than a grain and a half of sodium chloride to the ounce. When the acuteness of the attack subsides and the complaint begins to settle down into a chronic course, one may venture discreetly to widen the choice of remedies and bring into use some of the special drugs which act directly upon the secretory apparatus. Of these the remedies which increase blood pressure and hasten the circulation through the kidneys are of more service at this stage than drugs which stimulate the secretory cells of the tubules. Therefore, if blood pressure be not unduly high, digitalis is to be preferred to diuretin and caffeine. The next step, as improvement advances, is cautiously to make use of remedies which have a stimulating effect upon the kidney cells, such as caffeine, diuretin, spirits of juniper, and tincture of cantharides. In the choice of a diuretic in a case of cardiac dropsy one must bear in mind that the cause of the edema lies primarily in the chest, and not in the abdomen, and that remedies which act only upon the kidney are of little or no value unless combined with others which strengthen the action of the heart. Although as a cardiac tonic digitalis is the remedy most valued, its efficacy as a diuretic may be further enhanced by giving it in combination with other drugs which promote diuresis by different means. The citrate of caffeine is perhaps the most useful of these drugs in ordinary cases. This remedy, like digitalis itself, has the power of compensating for valvular insufficiency and improving the rhythm of the heart, and it has also its own special endowment of stimulating the kidney cells of the tubules. The combination is further strengthened by the addition of sweet spirits of niter as dilator of the afferent vessels of the kidney, in doses of 30 to 60 drops. A dram of the infusion of broom-tops given in conjunction with a dram of infusion of digitalis, 30 to 60 drops of spirits of nitrous ether, and 60 to 90 drops of the acetate of ammonia solution, is a diuretic of great value both in cardiac dropsy and in that which results from renal disease after the acute stage is at an end. When progress seems at a standstill, there are two drugs, either of which will often bring about a welcome change in the situation. One of these is tincture of cantharides. The dose may be 2 or 3 to 10 minims, according to the age, given several times a day. The tincture can be used in combination with any other remedy, and may be usefully added to a mixture containing caffeine, tincture of strophanthus, and spirits of niter. The other remedy which in obstinate cases can often be given with conspicuous success is mercury. Either calomel or blue pill may be employed. This remedy is well known as a useful addition to digitalis and squill, when these drugs are prescribed for their diuretic action, but it is when given alone that the effects of blue pill are most strikingly manifested.

The Serum Treatment of Diphtheria.—E. W. Goodall points out the advantage of the early use of antitoxin in diphtheria. In one-third of the cases in which this is used there appear symptoms of serum sickness, namely, fever, urticaria, or a variety of erythema multiforme, and arthritis. These symptoms rarely appear before the end of a week following the injection of antitoxin. They constitute what is called the "normal reaction." Besides this, there are other reactions due to serum, which have been called "abnormal reactions," because they differ very widely in their appearances from the normal reaction. In some cases the difference is rather one of degree than kind; but in others the phenomena are totally different from those of an attack of ordinary serum sickness. It was some time before these abnormal reactions were recognized and the circumstances under which they arose defined. They may be divided into two main classes—the one in which the patient has previously been injected with serum, the other in which he has not. The first class may be subdivided into three groups. The first, in which the symptoms appear after the usual incubation period of not less than one week, but they are unusually severe. In the second group the symptoms may or may not be of extraordinary severity or character, but the characteristic feature is that, while there is an incubation period, its duration is shorter than usual. Instead of being seven

days or more it may be twelve hours to six days. This is the "accelerated reaction" of von Pirquet and Schick. In the third group the symptoms of the serum reaction occur within a few minutes or five or six hours of the injection of serum. This is the "immediate reaction" of von Pirquet and Schick. An abnormal reaction may occur after a first injection. The symptoms in this class of cases are usually intense dyspnea, with failure of respiration and collapse. Very occasionally there is a rash, which is usually urticaria. One very important fact remains to be mentioned with regard to the second class of cases, namely, that the sufferers have many of them been the victims of asthma or some allied disorder. In some cases they have been persons who have had a peculiar idiosyncrasy to horses. The author is quite averse from using antitoxin as a prophylactic. Not only might it happen that the person treated was especially and peculiarly susceptible to the action of serum, even if he was not known to be asthmatic, but supposing that he was not naturally susceptible, it would not be unlikely that by the injection one would render him artificially so, in which case, if subsequently it were found to be necessary to use antitoxin remedially—a by no means unlikely event in these days of serums and vaccines—he would run the risk of undergoing a very unpleasant illness. The next question is, whether it is advisable to give antitoxin to persons who are only suspected to be suffering from diphtheria. The answer to this is that it is partly a matter of probabilities and partly one of the age of the patient. As a rule, doubtful cases of diphtheria are not severe cases, and in the cases of individuals over 10 years of age a delay of a day or two will clear the case up and not prejudice the patient's chance of recovery. In patients under 10 there is only one class of cases in which the diagnosis is doubtful and the disease dangerous—namely, the laryngeal cases.

Argyll-Robertson Sign in Cerebral and Spinal Syphilis.—J. M. Clarke states that the Argyll-Robertson phenomenon is to be regarded as an example of the selective action of a poison upon the central nervous system, inasmuch as a special group of neurons having a definite and restricted function is picked out and put out of action. So far as the author's cases go, they entirely support the contention that this sign is not a symptom found in pure cerebrospinal syphilis, and that its presence is an index of a degenerative process at work in the nervous system. The contrast with tabes and general paralysis, in which the sign is present in about 70 per cent. or over of the cases, is too striking to call for further remark. The author refers throughout to the fully developed Argyll-Robertson sign only, because merely sluggish pupils, although in certain connections suggestive, have not the same clinical significance. Further, it is now certain that in recent cases and under efficient mercurial treatment an absent light reflex may sometimes be regained. There are one or two other conditions under which the Argyll-Robertson sign may be present, but the associated symptoms should prevent any error in diagnosis. Thus the sign is present in cysts of the third ventricle and in tumors of the optic thalamus extending to the corpora quadrigemina. It has also been noted in lesions of the corpora quadrigemina, but it does not invariably accompany them. It is also present in optic atrophy, but not in optic neuritis.

Tuberculin Dispensaries.—A. M. N. Pringle expresses the conviction that the present state of knowledge does not incline him to the view that the establishment of a tuberculin dispensary under such conditions as proposed is an advisable procedure. He believes that the value of tuberculin will be best shown in a proper institution where the patients can receive that skilled control which the vast majority of authorities are agreed is essential to the safe and proper administration of the remedy.

Color Vision and Color Blindness.—By F. W. Edridge-Green. See MEDICAL RECORD, February 25, 1911, page 356.

Yellow Fever in West Africa.—Sir Rubert Boyce concludes that a comparatively large number of deaths and mild cases have occurred from yellow fever in the past, which have been attributed to malaria—chiefly the "bilious remittent fever." Most authorities upon yellow fever are agreed that in a very large number of instances "bilious remittent fever" is another name for yellow fever.

Berliner klinische Wochenschrift.

February 6, 1911.

Tobacco Psychosis in a Boy.—Pel of Amsterdam reports a rare case of a tobacco psychosis in a boy aged thirteen who worked in a cigar factory and smoked cigars continuously. The patient was very moody, restless, sleepless, and suffered from hallucinations and weakness of memory. Symptoms believed to be characteristic of nicotinism were absent (headache, tobacco-heart, amblyopia, etc.); nevertheless, the author chooses to regard nicotine as the cause of the psychosis, the patient's extreme youth possibly accounting for the predominance of psychical over somatic symptoms. Further, tobacco poisoning differs greatly in its symptoms with the individual. The psychosis in the present case showed its toxic character, and causal moments other than tobacco could be excluded. Nicotinism is very common in Amsterdam, and its diagnosis is often difficult because of the great individualization of cases.

Tetany, Epileptoid, Convulsions, and Psychosis.—Saiz of the Trieste Insane Asylum relates to a very complicated case which may be summed up as follows: There was severe chronic tetany with cataract formation, polydipsia, waddling gait, skin pigmentation, brittleness of nails, falling of the hair, epileptiform convulsions, etc. The hair and nail lesions indicated disturbances of nutrition. The psychosis resembled that of the epileptic twilight state, as do most of the tetany psychoses. There was confusion, followed by stupor and consecutive amnesia. There was evidently a close connection between the tetanic spasms and the convulsions. The author thinks that dementia precox can be excluded. Tetany is very rare in Trieste. The author seems to have little doubt that the affection is due to congenital functional weakness of the parathyroids.

Rickets as a Cause of Spinal Curvature.—Böhm's study of this subject leads him to two conclusions which he regards as highly important. In the majority of cases these curvatures are either congenital or due to rickets. Habit or school-scoliosis, on the other hand, seems to be due to mechanical causes acting on a normal spine. In the congenital and cachetic forms treatment must be begun at the earliest possible period. The author does not refer to prophylactic measures, but curative resources applied as soon as the diagnosis is manifest.

Peculiar Complication of the Pasteur Antirabic Treatment.—Frugoni and Gargiano report that soon after an injection a painful swelling developed *in situ*, something like a large wheal, and attained a maximum of development in 24 hours. The authors thought that such a lesion would presage a stormy general reaction, but it remained local throughout. However, in the given case, a similar lesion developed after each injection. This occurred in a certain per cent. of all cases treated. The authors are not yet agreed as to the nature of this phenomenon. It is not due to local infection. Possibly it is related to the so-called Arthus phenomenon.

Münchener medizinische Wochenschrift.

February 7, 1911.

White Pox.—According to Rudolph, a Brazilian practitioner, there exists a disease in both Africa and South America known to sea captains, missionaries, etc., as the

"white pox," which resembles variola very closely, but is not dangerous. The author describes a recent epidemic in Sao Paulo, Brazil, which he witnessed. He, with others, first diagnosticated it as variola, but on account of the extreme mildness of the affection the diagnosis was changed. Naturally varioloid must be thought of, but both vaccinated and unvaccinated have been attacked alike in the same degree. Varicella must also be borne in mind, but in some epidemics there has been a slight mortality, and a diazo reaction is present in most cases tested. There is nothing like a secondary suppurative fever. The affection differs from varicella in that the face suffers greatly. Typical pock marks were never noted, nor was there a true umbilication of pustules. Nevertheless, the disease is at times confluent, naturally in the face. The scarring is superficial and mostly disappears in a few months. There is no acquired immunity worth mentioning. The disease has not yet been successfully inoculated into animals. It has not been thought justifiable to inoculate human beings. Corpuscles are recoverable from the pus, which resemble those seen in variola and vaccinia, but thus far they cannot be cultivated. Ordinary vaccination does not take until about six months after the disease has elapsed. In brief, we appear to have here a new member of the disease group which includes variola, varioloid, vaccinia, and varicella.

Group Disease from Eating the Intestines of Pigs with Swine Plague.—Certain pigs developed an acute intestinal affection, with meteorism, anorexia, constipation, enlarged mesenteric lymph nodes, etc. This affection was proved to be the intestinal form of so-called swine plague or erysipelas. The owners used the intestines to make blood puddings, etc., and all those who ate of these products developed a typhoid-like condition. The chief symptoms were abdominal pains associated with obstinate constipation and meteorism, prostration, angina, dysphagia, high fever, etc. Some meal was first accused, as both the human and animal victims had eaten of it; but it was found to be wholesome. It appears, therefore, that the *Bacillus suipestifer* is able to produce a train of symptoms not unlike paratyphus fever and under similar conditions of eating infected flesh.

Haudek's Syndrome of the Penetrating Gastric Ulcer.—Holzknecht refers to the characteristic bismuth spots seen in the radiograph, which were wrongly interpreted until 1910, when Haudek showed that these were due to the filling of a cavity made in the investing tissues with bismuth. In an appended note Reiche defends the predecessors of Haudek, who were Jollasse and Hemmeter, in stating that these men worked under entirely different conditions from those of Haudek. The stomach was empty when the bismuth suspension was introduced, and the latter substance only adhered to the ulcer. Their interpretation was therefore correct. When the cavity is filled with bismuth the shadow greatly magnifies its actual size.

Aphthous Dermatitis.—Under the heading "dermatitis fibrinosa facies" Moro describes an eruption which he believes to correspond with aphthous stomatitis. Since there are a number of affections which may attack the skin and mouth and throat simultaneously, he would place aphthæ under this head. Some confustion with impetigo cutis is unavoidable, but the latter, as we understand it, does not affect the buccal mucosa. The cutaneous aphthæ are quite analogous to those of mucous site. They occupy the chin chiefly, and next in order the upper lip. The affection is of minor importance, but must be excluded in connection with impetigo.

Deutsche medizinische Wochenschrift.

February 9, 1911.

Diagnosis and Treatment of Secretory Disturbances in the Stomach.—Von Tabora gives a clinical lecture on this subject which in the main contains nothing new. He, however, lays great stress on certain practical points. He prefers to classify the secretory anomalies into initiative and depressive, the former characterized by increased, the latter by diminished secretion. Many cases of achylia (including hypochylia) gastrica are accompanied by chronic tendency to diarrhea. Such stools show an abnormal degree of putrefactive decomposition. In such cases protein food must be reduced to a minimum, and, generally speaking, in all the depressive anomalies there are two prominent indications: first, a preponderance of carbohydrates in the diet and, second, a restoration of the normal gastric juice. Pepsin alone is untrustworthy because often inert from age. Dilute HCl is indicated in theory and does good service in practice. It is antiputrefactive and is believed to rouse the latent gastric secretion to action. But superior to simple HCl is one of the recently introduced combinations of pepsin with solid substances containing HCl in loose combination. Several such are in the market. It is known that acid albumin or syntonin, which represents the first product of proteid digestion, may be so manipulated as to retain a large proportion of its acid when dried. This dried preparation may be mixed with active pepsin if necessary. The author finds that such a combination gives all the good results once universally believed to follow the simple exhibition of a pepsin HCl solution. Loss of faith in the latter seems to have been due largely to flooding the markets with inert pepsin and to the teaching of the modern gastrologists that pepsin is seldom indicated (because the propepsin already in the secretory cells is readily activated by HCl). To a certain extent the treatment of the initative secretory disturbances is diametrically opposite that of the depressive forms. A liberal diet, rich in proteid and fat, alkalies to neutralize excess of acid, and in certain cases atropine, are indicated.

Experiences with Salvarsan.—Heuck and Jaffé, dermatologists, sum up their experiences with salvarsan as follows: One or, at most, two injections in any stage of syphilis give results not only fully equal to those from the use of mercury but often far superior. There is no evidence of a sterilisans magna; the Wassermann reaction disappears too slowly to admit of such a possibility. Furthermore, relapses are sufficiently common to preclude the likelihood of such a claim thus far. The authors have seen no serious collateral or after effects, and of the number recorded by others it is as yet too soon to account for them satisfactorily. Contrary to the experience of many others, the authors find the remedy to act most potently and constantly in the earliest stage, and from this down to the latest and most malignant forms the action becomes progressively weaker and more variable. Under salvarsan infectious secretions soon dry up and spirochetes rapidly disappear. Mercury and salvarsan are good synergists and something might be expected from a prophylactic use of this association.

Local Tuberculosis from the Bacillus of Bovine Tubercle.—Heuser, after calling attention to the incompleteness of all extant case reports of this character, describes a personal case which is unobjectionable from any point of view. The patient was a slaughterer who injured a finger while dressing the carcass of a sick cow. A lesion developed *in situ* severe enough to prevent the man from working at his trade. A lymphadenitis developed in the axilla. When the patient first came to consultation he was also found to have a chronic lymphangitis of the arm, with here and there a nodule. The primary lesion showed all the properties of a tuberculosis verrucosa cutis. General condition quite normal. The tumors along the thickened lymphatics were extirpated or destroyed *in situ* with the cautery. Bacteriological studies and animal inoculations showed conclusively the presence of the bacillus of bovine tuberculosis. Reaction to human tuberculin was negative.

Book Reviews.

American Red Cross Abridged Text-Book on First Aid. Industrial Edition. A Manual of Instruction. By Major Charles Lynch, Medical Corps, United States Army, and 1st Lt. M. J. Shields, Medical Reserve Corps, United States Army. Prepared for and Indorsed by the American Red Cross. With 49 Illustrations. Philadelphia: P. Blakiston's Son & Co., 1910.

This industrial edition on first aid is intended for the worker in the industrial field. It is stated that it will appear in Polish, Lithuanian, Italian, and Slovak, as well as in English, so that it may be read by the majority of miners. In view of the large number of industrial accidents occurring annually, the value of a succinct manual such as this, which emphasizes the importance of the prevention of accidents, cannot be overestimated. The authors are to be commended for their skill in concentrating a vast fund of valuable information within the narrow limits of this book, which deserves a wide circulation among the soldiers of the industrial army.

Gynécologie Opératoire. Par Henri Hartmann, Professeur de Médecine à la Faculté de Médecine. Avec 422 figures dans le texte dont 80 en couleur. Paris: G. Steinheil, 1911.

This is the first work that has appeared in France dealing exclusively with the therapeutic aspects of gynecology. It is not solely an operative gynecology, as its title would indicate; it also takes up the non-surgical methods of treatment, as presented in the general chapters on the treatment of metritis, of diseases of the adnexa, of uterine deviations, etc., and in the chapters on minor gynecology and on the various methods of treatment by means of mineral waters, electricity, vibration, and massage. The operative procedures that are rarely performed are rapidly passed over, while the common surgical measures are presented in detail, with the aid of many illustrations, of a high order of artistic merit, many of which are colored. The author, in treating of the indications and results of each operation, seeks to show the reciprocal influence of the operation upon subsequent pregnancy, and of pregnancy upon the operation. This is an important point in determining the choice of operation.

Besteht ein Ätiologischer Zusammenhang zwischen parenchymatoser Keratitis und Verletzung? Von A. Vossius in Gieben. Halle, a. S.: Carl Marhold, 1910.

In this small brochure Dr. Vossius reviews the literature and also gives his observations on the excitation of parenchymatous keratitis in some syphilitic individuals by trauma. The proposition is apparently substantiated. The same process follows in the fellow eye, apparently by a form of sympathy.

The Extra Pharmacopœia of Martindale and Westcott. Revised by W. Harrison Martindale, Ph.D., F.C.S., and W. Wynn Westcott, M.B. (Lond.), D.P.H., H.M.'s Coroner for North-East London. Fourteenth Edition. 12s. London: H. K. Lewis, 1910.

Organic Analysis Chart. By W. Harrison Martindale, Ph.D. (Marburg), Pharmaceutical Chemist. A Supplement to the "Extra Pharmacopœia." Fourteenth Edition. 3/6. London: H. K. Lewis, 1910.

The successive editions of this unique work appear with almost the regularity and the frequency of a year book. That the editions are real editions, and not mere reprints, is made evident by the constantly increasing bulk of matter. To accommodate the additional material without increasing unduly the thickness of the volume the thirteenth edition was printed on such thin paper that the impression showed through, seriously interfering with the comfort of the reader. In the present edition the size of the page has been enlarged slightly and the paper, while thin, is opaque. The book is, however, just as handy to use as before, and the clearness of the printing makes it once more a delight to the reader. The work is adapted to the U. S. Pharmacopœia as well as the British, and is therefore just as useful to physicians in America as to those in the country of its publication. The new international atomic weights are noted and new sections have been introduced treating of the lactic acid bacilli, the organic arsenic compounds, iontophoresis, and radium, while a large number of new compounds and proprietary remedies are mentioned. There is no work containing a greater amount of practical information on materia medica and therapeutics in so compact a form as this, for it treats of the pharmacopœial as well as the extra-pharmacopœial preparations. It contains, in fact, more really necessary information than any dispensatory or treatise on materia medica, and all in a book 6½ inches in length, 4¼ inches in width, and 1 inch in thickness. The Organic Analysis Chart is of the same format, but thin, and contains full directions for the recognition of many chemical preparations employed in therapeutics. It is invaluable to the pharmacist and laboratory worker.

Andreas Vesalius: The Reformer of Anatomy. By James Moores Ball, M.D. Price, $5.00. St. Louis: Medical Science Press, 1910.

This is an example of book-making such as is seldom seen in medical literature. Of quarto size, printed in type of exceedingly pleasing cut on a heavy vellum paper, and very profusely adorned with reproductions of early anatomical and other drawings, it is the mechanical excellencies and beauties of the work that first attract attention. The text is no less noteworthy, however, and fully deserves the attractive dress in which it reaches the reader. Its production has evidently been a labor of love, and the introductory chapters form a most delightful series of essays on the history of the study of anatomy from its inception in Egypt and Greece to medieval times. Then follows a very thoughtful discussion of the influence of the Renaissance on the development of research in medicine, and a review of the work of Vesalius' predecessors in the field of anatomy. The remainder of the work, devoted to the great anatomist himself, is a fascinating recital of the achievements of the founder of modern anatomy, and a summary of his chief publications, the Tabulæ Anatomicæ, the Fabrica, and the Epitome. Too much praise cannot be given to author and publishers for having produced this delightful volume, which must appeal most strongly both to the bibliophile and to the student of medical history.

Interne Klinik der bösartigen Neubildungen der Bauchorgane. Von Priv.-Doz. Dr. Rudolf Schmidt, K. K. Primararzt am K. K. Kaiserin Elisabeth-Spital, Wien. Mit einer farbigen Tafel. Price, Marks 14. Berlin, Wien: Urban und Schwarzenberg; New York: Rebman Company, 1911.

The diagnosis of malignant growths of the abdominal organs is not yet as satisfactory as it should be, especially if the cure of the patient is to be considered. For, after all, the question is largely in making a diagnosis for the surgeon, and there is still a suspicion that that important personage makes many of his diagonses after opening the abdomen. However, this to a certain extent is necessary, because if an abdominal section is delayed long enough to enable the clinician to make a positive diagnosis of a malignant new growth, the patient is generally beyond any but palliative procedures. Further improvement, therefore, in our diagnostic armamentarium is of the utmost value, and such a book as this, which not only collects the important procedures, but also adds the results of a very wide clinical experience and keen judgment of its author to the illumination of such physical and chemical methods as are of value, should be in the hands of every practitioner of medicine. The arrangement adopted is in general and special parts. The general part contains a very full discussion of methods of physical investigation of the abdominal organs, including the *x*-ray and the various chemical and microscopical tests which experience has shown to be of real value. Especially full and satisfactory are the portions which treat of occult blood tests and those concerning the diagnostic value of the flora of the stomach and intestine. The special part takes up, seriatim, cancer of the stomach, of the large intestine, of the liver, of the gall-bladder, of the pancreas, and of the kidneys. A large number of illustrative case histories are appended, which are of interest because of the thorough discussion of the operative or autopsy findings on the patient as illuminating the symptoms and physical signs previously obtained.

Physician's Pocket Account Book. And Practical Advice for Professional Success. By J. J. Taylor, M.D. Philadelphia: The Medical Council, 1910.

This is a convenient little volume, bound in leather. It is designed as a physician's complete financial record, which by a special ruling and printed headings is so constructed that a complete legal entry of a charge can be made with very little writing. It also contains various business items, such as a table of fees, instructions for billing and collecting, the statute of limitations, forms for wills, dying declarations, saving and investing, treatment of poisoning, etc. There can be no doubt that this book fulfills all the requirements of medical bookkeeping in a most simple manner.

Society Reports.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

236th Regular Meeting, Held January 6, 1911.

THE PRESIDENT, DR. H. M. BIGGS, IN THE CHAIR.

Hydronephrosis of the Kidney as a Result of a Long-Standing Calculus.—Dr. C. L. GIBSON reported this case, which, he said, was due to a long-standing calculus. For at least ten years the patient had been passing purulent urine without intermission, and suffered also a great deal of pain on the right side. For some years his trouble had been diagnosed as a tuberculous kidney. The diagnosis of hydronephrosis of the kidney, the speaker said, was at once obvious. A very large mass occupied the entire right lumbar region; the other kidney could be felt, and it was obviously not tuberculous, as symptoms of cesical irritation were lacking for years. He never had any hematuria. The radiograph, too, showed the condition very clearly. The operation of lumbar nephrectomy was performed and the kidney removed, the whole leaving a very large cavity. The recovery was uneventful, and the patient is now fully restored to health.

Dr. L. A. CONNER asked how, if there had been enough obstruction to produce a hydronephrosis, could there have been a free discharge of pus from that kidney into the bladder.

Dr. GIBSON said that there had not always been free exit, but enough obstruction to prevent its escape, and that he had a large kidney on the other side. The speaker also stated that it had not been from obstruction alone that the hydronephrosis had developed. The patient had had an infection, but where it had come from he did not know. He had had a certain amount of hydronephrosis to begin with, and later he had become infected. The pus had been under considerable tension and had to come away.

Intradural Section of the Posterior Spinal Nerve Roots (Dana's Operation).—Dr. ROBERT ABBE read this paper (see page 377).

Dr. C. L. DANA thought that the operation, as Dr. Abbe had said, had come to stay, and that it would be much more extensively and much more widely applied for the relief of pain. Dr. Jacoby had reported a similar operation for the relief of pain with perfect result. The operation had been employed for relief of pain in the crises of tabes and had been satisfactory, and, so far as the speaker knew, permanent. In late years the operation had been performed for spastic conditions, and Drs. Taylor and Clark had employed it in Little's disease with some success. In paraplegia, too, it had been used with some relief. The first fatal case in the speaker's experience was in the case of a child six years old, who had been operated on for Little's disease. Cutting the posterior roots, Dr. Dana said, was much more rational than cutting the posterior branches of the cervical nerves which he had never seen produce good results. The operation, too, had been performed on other forms of trouble, such as pains in locomotor ataxia, where the pains were absolutely localized.

Dr. M. A. STARR said that the first case reported was one that he had had under his own observation. The patient had impressed him as having had a decided psychical element in his pain, and, as he recalled it, he had not been much benefited by operation. He stated that he would like to put on record a case that seemed to him to have been particularly suitable for this operation, but which it had failed to relieve. The patient was a French Canadian, who had been sent to him about one year and a half ago by Professor Raymond of Paris. This patient had been seen by physicians in Paris and Canada, and he did not appear to have been neurotic. For six years he had suffered the most violent pains in the domain of the sixth intercostal nerve on the left side, and so excruciating had been the pain that morphine had been employed sparingly, although Dr. Starr was very much averse to its use. Every therapeutic method had been considered, until the only thing left to be done was an intradural division of the nerve. The fifth, sixth, and seventh dorsal nerve roots were cut. As a result of this division of the three nerves a band of anesthesia about three-quarters of an inch wide around the surface of the thorax had been established, but there had been no relief from the pain, which has continued down to the present time. Another case in which Dr. Starr had recently advised operation was a man who, in addition to his locomotor ataxia pains, had suffered for two years excruciating pains in the intercostal nerve on the left side. While it seemed theoretically of value and had been of service, Dr. Starr said that he had been impressed by the lack of result of this intradural section of the nerve roots in these cases. Immediate relief was secured in trigeminal neuralgia by cutting the Gasserian ganglion. The patient never had any pain after the operation. This was not the case in division of the dorsal nerve. The speaker said that there were some kinds of pain in which there was a good deal of central pain of unknown origin set up in the brain rather than in the spinal cord or peripheral nerve. He felt that where the patient had not been relieved by the operation, but had cried out spontaneously, it was an example of central pain rather than an irritation of the nerve or nerve roots. Dr. Starr said that it was difficult to distinguish central from peripheral pain.

Dr. DANA said that in no case was pain relieved by the section of three roots; that to bring about this result more had to be cut.

Dr. ABBE closed the discussion by saying that in one of his cases, when the patient was not under ether, when the posterior columns of the spinal cord were touched, the patient cried out that "he could not stand it," whereas the roots alone could be touched without eliciting pain. In answer to Dr. Starr's comment that in these persistent neuralgias not relieved by root section there was in his mind a feeling that the pain origin was in the brain, Dr. Abbe felt that the diminishing pain during seventeen and twenty-two years after operation on the spinal roots argued against central disease, at least so far as tumor growth or other progressive changes could go.

Sodium Cacodylate in Syphilitic Iridochroiditis.—Dr. M. ALLEN STARR said, in reference to a successful case of this nature reported at a former meeting by Dr. C. S. Bull, that he had had a case in which employment of sodium cacodylate had been without result.

Dr. C. S. BULL said that he had had a fourth patient with chorioretinitis syphilitica under treatment to whom he had given eleven injections of sodium cacodylate without the slightest improvement. This patient had previously been through a thorough course of treatment by mercury and potassium iodide without benefit.

Bilateral Nephrolithiasis.—Dr. C. BOLTON BANGS reported this case (see page 394).

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held February 2, 1911.

THE PRESIDENT, DR. WILLIAM M. POLK, IN THE CHAIR.

Some Recent Decisions of the Courts in Suits for Alleged Malpractice.—Dr. STEPHEN SMITH made this address. He said that the civil obligation which the surgeon assumed when he undertook the practice of the art of surgery might be traced to remote antiquity, and its development had been along the lines of progress in the organization of civil government. The first recorded method of treating the sick was to expose them in public places in order that any passerby who had been affected

with a similar disease and had been cured by some special remedy, could give the sufferer the benefit of his experience. At a later period those who had been cured of diseases were required to deposit in the temples a votive tablet which contained a detailed account of the symptoms of their respective ailments and a minute statement of the remedial agents which had proved most beneficial. This collection of votive tablets became popular as records which the sick could consult with great certainty that each would find his own case described and the appropriate remedy prescribed.

In the course of time these records became very voluminous, and there were misinterpretations and remedies were misapplied. This led to the withdrawal of the records from public scrutiny, and the priests had entire control of the recorded facts and monopolized the practice of the healing art. The records were next reduced to a system by collating the facts in the form of a code of practice. Later these records, revised and collated, were regarded as of such public importance as to be published under the title of "The Sacred Book." This book was the undeviating guide to medical practice for centuries. The practitioner who departed from its precepts did so at the peril of his life. All questions of practice were determined by this code and every violation of its sacred aphorisms was punishable by death. The influence of the "Sacred Book" could be traced through all subsequent ages. It was still held, nearly in the language of the sacred text, that any deviation from the recognized principles and methods of practice shall be deemed sufficient to charge the surgeon with malpractice in case of an injury arising to the patient. This rule admitted the adoption of new remedies and modes of treatment when their benefits had been demonstrated, or when, from the necessities of the case, the surgeon was left to the exercise of his own skill and experience. While it was necessary to recognize some standard, it was evident that no kind of standard could have permanent value as a just criterion established by custom, public opinion, or general consent, for art was progressive and the principles which governed its practice changed from time to time with the advance of science and experience. These changes took place gradually. In order to determine the standard of the practice of surgery in any given case, it was necessary to consult the opinions of its acknowledged authorities and public exponents at the particular time, and in places similar to that in question. On this fundamental legal principle rested the civil obligations and responsibilities of the surgeon in the practice of his art.

Dr. Smith showed how the courts had established the principle that a physician, unless he was an officer of the government charged with specific duties which he thereby violated, could decline to take charge of a particular case. When the surgeon took charge of a case the relation of surgeon and patient was established and mutual obligations existed either in express or implied terms. The consulting surgeon did not stand in the relation of surgeon to patient. Cases were cited in which the principle had been established that the surgeon was responsible for this agent, but the evidence must establish the fact and relationship of agency. The Supreme Court of Missouri had upheld the principle that the examination of a patient without treatment might establish the relation of surgeon to patient. A surgeon duly appointed to a hospital holds the relation of surgeon to each patient admitted for treatment, of whom he assumed the care, either personally or through his subordinates. The surgeon who assisted in applying dressings stood in the relation of surgeon to patient. A decision of the Court of Appeals of New York had determined the status of the surgeon when services were refused by the patient. The court held that when one was sick unto death and was in fact treated by a physician as a patient, even against his will, he became the patient of the physician by operation of the law. The same was true of one who was unconscious and unable to speak for himself.

The speaker discussed the term "contract" when called an express contract and when an implied contract, and said that the failure of surgeons to realize the existence of the obligations of a contract whenever they assumed the treatment of a case had often resulted in the neglect of details in its management that might readily have been avoided. This neglect became an action for malpractice. So much importance had latterly been attached to the contract as a protection against prosecutions, that surgeons had been advised to adopt the practice of artisans, and in all severe and complicated cases to make attendance contingent upon an express contract, written and signed.

The consent to an operation by a patient or some responsible person was too often disregarded by surgeons. A review of the cases brought into court for alleged malpractice showed that where specific consent was not obtained prior to the operation, authorizing the surgeon to use his discretion in the treatment of unforeseen complications and conditions which might be met in the progress of the operation, the position of the operator might become exceedingly embarrassing. Consent might be expressed or implied.

A number of cases were cited, illustrating the confusion and serious misunderstandings which were liable to occur when the consent was verbal, among which was the following: An action was brought to recover damages for the wrongful operation by a surgeon upon the patient, the claim being that the surgeon was employed to operate on the right leg, but after putting the patient under the influence of chloroform he operated upon the left leg, thereby causing the patient great pain and suffering. The plaintiff testified that both legs had troubled him for several years; sores came out on the shin bones and were healed; the right leg continued to be sore. He consulted the defendant, who treated him for several months without improvement. The defendant then advised him to be operated upon. He went to the hospital on crutches, using his left leg. The following morning the nurse prepared him for operating by shaving his right leg from the knee down, as the operation was to be on the shin bone; nothing was done to the left leg. The nurse testified that the plaintiff had a swelling of both legs and the witness asked him which leg was to be operated upon and he said the right leg, so he prepared that leg. A brother of the plaintiff testified that he was present at the operation, that he had swelling of both legs, and that when the plaintiff was placed upon the operating table both legs were exposed to the defendant, who said, "See here, you fellows have made a mistake; you have prepared the wrong leg for operation." The defendant asked him which leg he wanted operated upon and the brother replied that he was confused and did not know, but could telephone his folks so as to be sure; the defendant consented to wait, but the father came in the meantime and said it was the left leg. The father testified that he arrived at the hospital after the plaintiff had been put upon the operating table; that they showed him both legs, and defendant said, pointing to the right leg, "Is that the right leg?" "No," I said, "the other leg. I had my mind on that leg all the time." The court directed the verdict in favor of the defendant, stating that the case turned upon the question of whether or not the doctor was negligent in operating upon the left leg instead of the right. There was nothing in the case that would warrant the jury in finding a verdict on the theory of negligence. After reciting further facts the Appellate Court decided that the case should have been submitted to the jury for their determination whether the defendant exercised the degree of care which, under the circum-

stances, he was bound to exercise, and the judgment was reversed and a new trial granted. The Supreme Court said there was no claim that the doctor did not have the skill and knowledge necessary for the operation. The declaration averred negligence on the part of the defendant in operating on the left instead of the right leg. They did not agree that there was no evidence tending to establish the fact that there was negligence on the part of the defendant.

Another case was cited in which the surgeon operated upon the left ear when he had obtained consent to operate upon the right. After anesthetizing the patient the surgeon had discovered that the left ear was more seriously diseased than the right and operated upon that. The defense claimed that the patient by putting herself in the surgeon's hands had tacitly consented that he might do so if he deemed it advisable in the exercise of his best judgment. The judge who presided at the trial held that no such consent could be implied from the circumstances of the case, and that the defendant was at all events liable for a technical assault. The jury gave the plaintiff a verdict for more than $14,000. On a retrial of the case the plaintiff again recovered verdict, but this time for $3,500. The trial court granted the defendant's motion for judgment notwithstanding the verdict for the plaintiff, and from that order the plaintiff again repealed. The reported cases show that doubts and difficulties arose chiefly when the consent was verbal or implied and thus emphasis was given to the value of the written contract which had been advocated.

The modern practice of surgery had resulted in leaving substances in the wounds and suits for malpractice had followed. In many of these the verdicts had been in favor of the plaintiffs. There was a widespread sentiment in the medical profession that the courts showed but slight appreciation of the peculiarly difficult conditions under which the practisers of that art were compelled to perform their duties, and that the legal rules governing the trial of cases of alleged malpractice were applied with marked discrimination against the defendant. This sentiment had no just foundation. It had its origin in an unfamiliarity with, or a misconception of, the rules governing the admissibility of evidence which had had the sanction of the most noted jurists for centuries. On the contrary, there was ample evidence that the courts had uniformly recognized the medical profession as devoted to the most sacred of callings and had shown a proper appreciation of the manifold difficulties which daily beset the surgeon in the performance of his duties. Judges had shown commendable judgment in protecting him from hostile treatment provided it appeared from the evidence that he had brought to the treatment of the case ordinary learning and skill and had exercised proper care and diligence in applying that learning and skill. It was equally true that these decisions showed that the courts had judiciously discriminated between the legitimate practiser of surgery and the mere pretender, and that charlatanism in every form had received severe rebuke when its practices had come within the purview of legal tribunals.

Dr. Smith also reviewed several cases in which negligence in the use of the *x*-ray was claimed. In one instance the court charged that the jury could not find the defendant guilty of negligence unless it could find in the proofs some particular act of negligence which caused the burn. To punish the defendant because he could not explain the cause of the burn was not necessarily to punish him because he had done wrong, but might be to punish him because he did not know something which science could not find out, or had thus far been unable to find out. That would be manifestly unfair. The rule of liability in these cases was the same as that applied in other actions for malpractice and one of ordinary care and prudence.

PELLAGRA AS WE SEE IT IN ITALY; OLD AND NEW THEORIES; WITH REPORT OF CASES SEEN IN NEW YORK CITY.*

By A. CACCINI, M.D.,

NEW YORK.

FORMERLY OF THE HOSPITALS OF ROME AND INSTRUCTOR OF MEDICINE IN THE ROYAL UNIVERSITY OF ROME; ASSISTANT AT THE CORNELL UNIVERSITY MEDICAL CLINIC; PHYSICIAN TO THE HARLEM TUBERCULOSIS CLINIC OF THE DEPARTMENT OF HEALTH.

In view of the interest recently shown in the study of pellagra in the United States, the primary object of this article is that of describing the disease as we see it in Italy, where it is quite an everyday experience, and of showing that it occurs more frequently in this country than is generally believed; cases of it may be found in New York City itself, provided the disease be kept in mind and looked for, particularly among large classes of foreign patients. In Italy, where there are 100,000 registered cases, and a most productive literature, the disease does not develop with such acute symptoms and cutaneous manifestations as in the United States. Doubtless it will later be accorded its importance as an element in the economic development of the United States, as well as given a place in North American medical literature, as has been the case with the Southern European nations. Modern textbooks on medicine in the United States devote only a few lines to this disease, and recent reports on pellagra in the United States limit to three the number of cases of the disease in the entire State of New York.†

"Pellagra" is a word of the dialect of Bergamo, Italy, where the disease first appeared, and is a compound of the words "pelle" (skin), and "agra" (rough). Foreign writers erroneously derive it from one Latin and one Greek word, viz., "pellis" (skin), and "agra" (a seizure). Particularly in view of the recent discussions as to the etiology of the disease, I believe that a good definition of it is still that of Bouchard: "La pellagre est un maladie générale chronique, à exacerbations vernales, caractérisée par des désordres variés du tube digestif et de l'axe cérébrospinal et par un érythème qui siège sur les parties exposées aux rayons solaires." (E. Gaucher, *Traité des Maladies de la Peau*, Vol. 1, page 124, Paris, 1895).

Lombroso, from the testimony of Barnino, Maffei, and other writers of the sixteenth century, gathers a description of a condition similar to that of pellagra, affecting the North American Indians, who fed on damaged corn. Spanish writers of the same period describe a disease that was frequent in Mexico, affecting horses which fed on corn (paretic or tabetic conditions, with loss of intelligence and hair). Since 1735 Consal observed pellagra among the peasants of the Asturia provinces of Spain. He described it only in 1765, and called it "mal de la rosa." Italian observers described cases somewhat before Frapolli (1771) published a description of it differentiating it from other diseases. There is reason to believe that it had long before existed and that it was simply overlooked, by the fact that in 1789 it had so vastly spread throughout the northern part of the country that the government of Joseph II had to open a special hospital at Legnago. It travels very slowly, for we see that after a lapse of two centuries since it was first described in Italy, it is only now beginning to invade the central and southern provinces.

Interesting observations were published in Italy by Zanetti, Gherardini, Odoardi, and Fanzago in the eighteenth century, before Consal's work became popular; it was Fanzago who, in 1789, revealed the identity of the new disease in Italy, with the "mal de la rosa" of Consal. Hameau in France, in 1828, communicated to the Académie de Médecine of Bordeaux cases observed by him ever since 1818. About 1850 it was discovered in Roumania, Poland, and Greece. Roussel, in his "Traité de la Pellagre," Paris, 1866, describes cases in North Africa. At present the disease is limited to certain portions of the northern provinces of Spain, the western and southern provinces of France, northern and central provinces of Italy, and the Danubian and Balkan States—Moldavia, Walachia, Roumania, Greece, and Poland. It occurs frequently in Egypt and occasionally in India, Mexico, and South America. Dr. Sandwith presents statistics of 500 cases at the Kasr-El-Ainy Hospital of Cairo.

In the United States the disease has been described only lately, occurring sporadically; and after the publication of cases seen by Gray of Utica, N. Y., and Tyler of Somerville, Mass., no case was recorded in the North American medical literature until 1883, when Sherwell, and later Harris of Atlanta, Ga., described one case each. It was not until 1907, after the observations of E. J. Wood, R. H. Bellamy, and J. B. Wright, all of North Carolina, that the disease attracted much attention in the United States. In 1908 J. J. Watson and J. W. Babcock of South Carolina identified the disease as the Italian pellagra. At the present time, although in small number, cases are discovered all over the country.

Owing to some peculiarities of the disease in different years and in different localities, as well as to other secondary causes, it is difficult to give reliable statistics regarding it, the only true data being those obtained from hospitals and asylums. Inquiries conducted in asylums by the South Caro-

*The preparation of this article is due to the suggestion of Dr. W. G. Thompson, whom I have to thank for encouraging me to present an illustration of the cases as well as the European viewpoint of the disease.

†"Prevalence of Pellagra," by J. W. Babcock, *Journal of the South Carolina Medical Association*, September, 1910, pp. 445-449.

lina State Board of Health, in cooperation with Surgeon-General Wyman, of the United States Public Health and Marine Hospital Service, have shown that cases are present in about twenty States. In South Carolina there are about 500 cases; in Georgia, 225; in Alabama, 160, etc. As to New York State, only a few cases are mentioned in the report, these being found in the vicinity of Brooklyn.

In Italy, it seems that, while the disease is gaining in extension, it is losing in virulence. Another fact is evident from statistics, namely, that women are more susceptible to the disease, perhaps on account of debilitating elements, such as pregnancy, the puerperium, and the rearing of children. In Italy there are 100,000 registered pellagra cases in a population of about 37,000,000. Roumania has about 50,000 cases out of 5,800,000 inhabitants. In certain sections of Italy about 50 per cent. of the rural population is pellagrous. Again, in Italy, there were, in 1884, 10,000 cases in asylums. Ten per cent. of all cases in asylums are insane.

Etiology.—Every race and nationality is susceptible to the disease. It is not hereditary, but the children of pellagrins certainly show lowered resistance against the disease, and are anemic and poorly developed mentally as well as physically.

The "damaged corn theory," or "maidism theory," had been advanced long ago by Frapolli, Zanetti, Strambio, and others in Italy (1771-1794), and by Consal in Spain (1735-1750). As a result of the researches of Frapolli, the sanitary government of Milan, in 1771, and that of Venice, in 1776, enacted prophylactic regulations against the diffusion of pellagra, to the effect that no damaged corn should be sold in their territory.* But political conditions prevented further study of the subject on the part of the government until 1844, when Balardini brought the argument again into discussion, that the *Sporozoidium maidis* produced the disease. In 1864 Lombroso undertook researches in regard to the subject and came to the conclusion that maize, if harvested too early, or if not properly ripened and dried, breeds certain microscopic fungi (penicillii and aspergilli) whose toxic products, acting on the nervous centers, produce the syndrome of pellagra.† Lombroso attributed the symptoms of the disease to the combined opposite action of two toxins produced by the penicillii and aspergilli in the fermented maize; one producing the excitant action (resembling strychnine), the other having a depressing action (resembling hemlock). He reproduced the symptoms of the disease in men and animals by administering the alcoholic extracts of damaged corn. Maiocchi, Marchi, Paltauf, Meider, Vassale, Cuboni, Ceni, Besta, Tizzoni, Fasoli, Cecconi, and others have isolated and described various microorganisms, most of them at post-mortem examinations, from the nervous centers of cases of pellagra. Most of the attempts directed to find new facts in the etiology of pellagra, while worthy of consideration, are still in need of confirmation from other observers.

C. H. Lavinder (*Public Health Reports,* June 3, 1910) presents the following account of Sambon's theory of this disease: "Pellagra is not due to maize, either good or bad, because: 1. It is found in places where maize is neither cultivated nor eaten. 2. It is absent from many places where maize is the staple food of the population. 3. It has in many places either decreased or become more prevalent without any change in the food of the people. 4. Its constant and peculiar distribution does not agree with the very irregular and ever-changing distribution of spoiled maize. 5. In over a century and a half, since the maize theory was first suggested, no one has been able to prove it. The belief that the disease has everywhere followed the introduction of corn cultivation is unfounded. Pellagra was first recognized as a specific disease in the beginning of the eighteenth century, but this does not prove that it was not prevalent long before that time.

"Pellagra is a parasitic disease because: 1. For years the person affected may present some seasonal recurrences, which can only be explained by a parasitic agent with alternating periods of activity and latency. 2. It shows a constant and characteristic topographic distribution. 3. It shows a definite seasonal incidence. 4. Its symptoms, course, duration, morbid anatomy, as well as its therapy, are similar to those of parasitic diseases. 5. Of two places, almost contiguous, one may be affected, the other not.

Pellagra is an insect-borne disease because: 1. It is limited, like malaria, sleeping sickness, etc., to rural places, and more especially to the vicinity of certain water bodies. 2. It has a definite seasonal incidence—spring and autumn. 3. It affects, to a large extent, a certain class of people—the field laborers. 4. It is not contagious and neither food nor water can account for its peculiar epidemiology. 5. Within its endemic centers it affects all ages and frequently whole families. 6. Outside its endemic centers only adults who have visited the infection areas present the disease and frequently only one or two members in a family are affected.

"Pellagra is conveyed by *Simulium reptans* because: 1. *Simulium* is found in the torrents and swift running streams of all pellagra districts. 2. *Simulium* has the peculiar seasonal distribution of pellagra, spring and autumn. 3. *Simulium* is found only in rural districts. It is unknown in towns and villages. It does not enter houses. 4. *Simulium* explains most admirably the peculiar limitation of the disease to field laborers. 5. *Simulium* is the only blood-sucking insect which the British Field Commission has found in its visits to numerous pellagrous districts in Italy. 6. *Simulium reptans,* like *Anopheles maculipennis,* has a world-wide distribution and explains the wide distribution of pellagra. It is found wherever pellagra is found. 7. *Simulium* causes epizootics in animals in America and in Europe. 8. Professor Mesnil has found a protozoal organism in *Simulium.*"

This theory, like any other, can be the subject

*Most intelligent laws were enacted by which the importation of maize was carefully surveyed and mills were inspected by the "Ispettori della Sanitá." The notification of cases of pellagra was made compulsory, thus enabling the government's officials to trace the occasional smuggling of damaged corn. Severe were the penalties for such crimes as the importation, the selling, or even the keeping of rotten corn. The priests were required to join the educational campaign by explaining these laws in the churches. It is certainly interesting to note this display of Yankee ingenuity in the middle of the eighteenth century.

†The immature corn is shrunken and whitish; the outer part being mother-of-pearl like; the embryo is visible through it and it is surrounded by a cavity. The damaged ripe corn is entirely different; the color is yellow, but there are visible green or black spots showing where the colonies of moulds started. The cuticula is cracked. The embryo is lesioned and often black. The tissue contains cavities filled by the powdery spores of the different moulds that have penetrated into the grains through the skin. The damaged corn has a characteristic and frequently very offensive smell, and the meal has a decidedly bitter and unpleasant taste.

of many a criticism, as none of the points can be considered of more account than those of any other theory. It could be objected that, like *simulium*, many other insects have the same habitat and habits, and that researches, if at all undertaken for *simulium*, should be similarly conducted for any one of the others.*

Fig. 1.—Facial expression in two cases of Italian pellagra. (From a photograph kindly sent by Dr. J. W. Babcock of Columbia, S. C.)

The latest theory on the subject has been furnished by J. D. Long, Past Assistant Surgeon, Public Health and Marine Hospital Service, Washington, D. C., in the *Journal of the American Medical Association*, August 27, 1910, and is as follows: "Pellagra is a disease resulting from an injury to the intestinal mucous membrane, produced by the ameba. As a result of the ulceration there is an inflammatory process, extending throughout the alimentary tract, which interferes with the absorptive power of the intestine and the manufacturing of the digestive ferments normally produced in the intestines. Later, owing to long-continued inflammation in the intestine, the pancreas and liver undergo inflammatory change which interferes with the quality and quantity of the digestive juices that they produce, with the result that the food ingested is improperly digested. The presence in the intestine of undigested food favors fermentation and putrefaction of its elements, with the production of certain toxins, ptomaines, and intermediate products of digestion which are harmful to the body.

As it has been shown by Herter that the *Bacillus acrogenes capsulatus* is present in the intestines of carnivora, and readily ferments proteid matter, it was decided to look for it as one of the possible causes of the fermentation. The fermentation of the carbohydrates could be accounted for by the colon bacillus.

"The insanity of pellagra was assumed to be due to the severe and long-continued toxemia. The lesions on the hands, neck, feet, face, and genitalia were assumed to be due to two factors: 1. The mechanical pressure on the nerves at their exit from the spinal canal, and 2. The degeneration of the nerves themselves as a result of toxemia. The degeneration of the cord was assumed to be due to the long-continued mechanical pressure on the posterior roots of the spinal nerves, which would tend to have the same effect as section of the nerve. It was assumed that the seasonal recurrence of the disease was due to the extremes of atmospheric temperature which exist during the so-called pellagra season, namely, March, April, and May, and September, October, and November. This assumption was not formulated until I had been in Columbia some time and had noted the changes myself."

Professor G. Alessandrini has just published the result of his investigation on the basis of Sambon's theory, that pellagra is a disease resulting from inoculation. (*Il Policlinico*, Supplement, May 15, 1910, and June 26, 1910.) From his investigations the author reaches the following conclusions: 1. There is a very strict connection between pellagra and drinking water. 2. Pellagra exists with a tendency to increase where the water of shallow and unprotected wells, or of cisterns, is used, and is absent, or diminished, when the drinking water is properly protected by mains, or taken from well-protected wells, either natural or artesian. 3. In the unprotected water, or in the superficial wells, there can be found larvæ of nematoda, belonging to the family "filaria," which produce the disease.

Pathological Anatomy.—While so many lesions are to be found at post mortem examinations and no organ may be found normal in cases of advanced pellagra, still these lesions are to be referred largely to the state of general cachexia. The characteristic lesions are to be found in the nervous system, particularly in the spinal cord. The meninges are opaque and thickened, often adherent with osteomata (*arachnitis ossificans*), particularly in the dorsolumbar region and in the medulla almost exclusively on the posterior or lateral posterial faces. While sometimes there is an evident anemia of the meninges, still when there are in life spastic symptoms (particularly in cases of pellagrous typhoid), there is a hyperemia of the dura mater and arach-

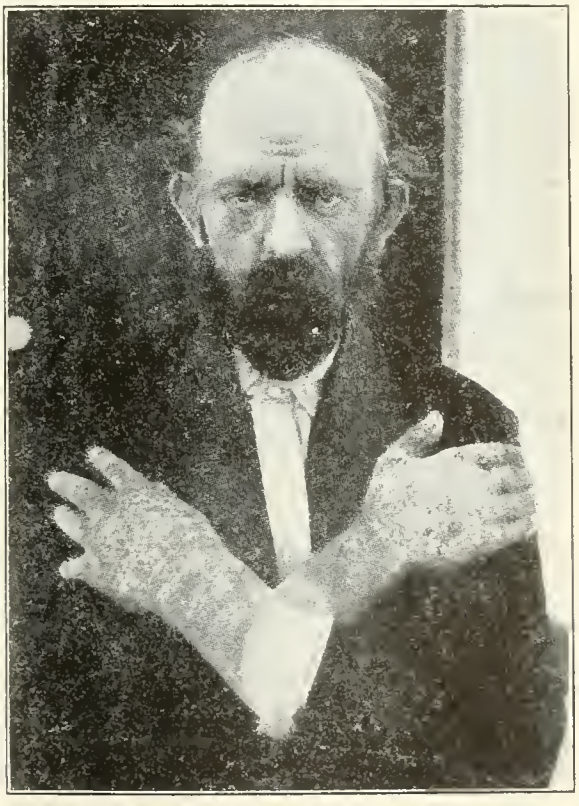

Fig. 2.—Showing characteristic facial expression in a case of American pellagra. (Dr. J. I. Watson.)

*The study of disease-carrying insects still has in store great surprises. It is only recently that the so-called "three-days fever" (a disease the symptomatology of which strictly resembles that of dengue) was discovered to be transmitted by the *Phlebotomus pappatasii*. Previously the disease was attributed to other causes, such as the dust from certain country districts where the disease is common (Durelli e Cevaschi), to the *Bacterium coli* (Mennelle e Mendes), to the hemp pollen, or to an ameba circulating in the blood.

noid with increase of the cerebrospinal liquid, which is often turbid or hemorrhagic. There are in the medulla acute and chronic lesions, and the acute are associated with the chronic in cases of pellagrous typhoid. The acute lesions are acute meningomyelitis, showing abundant infiltration of leucocytes in the meninges and in the medulla, dilatation of the vessels and sometimes hemorrhages in the medulla with destruction of fibers. The chronic ones show microscopically constant asymmetry of the two sections of the medulla, particularly the gray substance, general hyperemia, diminution of weight, softening, particularly of the dorsal and dorsolumbar section, with edema and anemia. (Tonnini and Belmondo.) Microscopically, there is an almost constant degeneration of the *fascia pyramidalia cruciata*, varying from a slight diminution of the transverse section of the fibers and destruction of the myelin substances, to the rarefaction and most intense sclerosis that affect the microscopic structure of the medulla. Also characteristic is the degeneration of Goll's column, generally limited to its cerebral portion. Belmondo describes a similar lesion of Burdach's column, a lesion found by Tuczek, but very rarely. The most typical cases showing such lesions correspond exactly to the description of incipient tabes, only that, contrary to what happens in tabes, the lesions are all above the lumbar section of the cord. There is atrophy of the ganglion cells (pigmentary atrophy) (Tonnini and Belmondo). This particularly is the case in the cellular elements of the anterior cornua. Tonnini, Tuczek, Lombroso, Marchi, and Barezzi have found such a degeneration in the sympathetic and spinal ganglia. Information concerning the lesions in the brain is yet very uncertain.*

The gastrointestinal tube shows the lesions of a common chronic enteritis. Vassale isolated a germ from the intestine in which the glands of Liberkühn were almost destroyed. The spleen and liver are generally reduced in size. More important is the friability of some bones, viz., the ribs. This Lombroso attributes to an eccentric atrophy and medullar hypertrophy. The skin of the hands shows the lesions of erythema, sclerosis of the bloodvessels of the papillæ and derma, and an atrophy of the corneal strata.

Pathogenesis.—The clinical observation of the disease seems to indicate that the conception of an intoxication will better explain the different manifestations of the disease than that of a defective metabolism. It seems reasonable to admit that the principal cause of the disease is the introduction into the circulation of a substance poisonous in character for the whole body, but particularly for the nervous system. The selective character of this substance for some territories of the nerve centers would explain certain alterations. (Belmondo.) As to the origin of the spinal lesions which characterize the disease, it is generally admitted that they are to be referred to a primary degeneration of the nerve fibers, rather than to a preceding hypertrophy of the sustaining tissue of the spinal cord with the alteration of the vessels, or to a meningeal inflammation with diffusion to the spinal cord, and secondary degeneration of the nerve fibers.*

Symptomatology.—Following the classical distinction of Roussel, pellagra can be divided, as to its duration, into three periods.† First period: Generally speaking, there are two different moments to be distinguished during the first period: (a) initial pellagra, preceding the cutaneous eruption, (b) pellagra conclamata, comprising all the full developments of the disease, together with the erythema.

Initial pellagra: Generally at the beginning of spring, sometimes in the early autumn, the disease starts with a prodromic period, the patients

Fig. 3.—Pellagra eruptions on face, neck, elbows, hands and knees. (Dr. J. J. Watson.)

*In the acute cases the cortex shows the reparable lesions: swollen nerve cells with nucleus showing increased affinity for stains and the protoplasm disintegrated. The nucleus of the motor cells of the cortex is displaced to the periphery; the cells are rounded, the processes are atrophic, and the center of the cells is pallid; the nucleus toward the center of the cells shows small accumulation of chromatic substance. These same lesions are found in like acute disorders (delirium tremens and many cases of amentia). In cases of pellagrous dementia there are lesions of a chronic nature like sclerosis, proliferation of neuroglia and lymphocytosis.

*Tanzi classifies into five groups the many interpretations of the theory based on the toxic nature of pellagra: (1) That of Roussel in France: Corn is always poisonous by itself, like other grains that give symptoms similar to those of pellagra. In contrast to this interpretation there is the fact that in some countries corn is used and pellagra is unknown.

(2) Only unripened corn is poisonous like the Quarantino and the Cinquantino. In contrast to this interpretation stands the fact that the disease is common where these varieties are neither used nor grown nor imported.

(3) Corn is rendered poisonous by the action of some unknown recurrent secretions. This interpretation is at least too vague.

(4) The poison is formed in the body only from damaged corn, which would seem to be the vehicle of substances that become poisonous after ingestion. This interpretation lacks at least precision as to the place and the means of formation of the poisonous substance.

(5) Only damaged corn is poisonous (Ballardini and Lombroso). Pellagra thus being an intoxication from a diseased grain, the parasites of corn are not infective to animals.

†Needless to say, this division, like any other, is an artificial one. It is based on the intensity of the symptoms, not on the duration of the disease. For this reason the various symptoms are described, remarking when necessary the difference between the various stages, which is based on the intensity of the symptoms.

complaining of indefinite malaise and an unusually tired feeling, which makes ordinary occupations too burdensome. These prodromes are often overlooked: they are malaise, eructations, thirst, and dryness of throat and esophagus, dizziness, itching

Fig. 4.—Italian type of erythema.

all over skin, pain along the spinal column and in the limbs, ringing in the ears, diminished eyesight, sleeplessness, and headache. Patients become melancholic, losing ambition for work, and sometimes becoming susceptible to emotional disturbances. The dryness and burning of the esophagus, which soon diffuse to the stomach and become a genuine pyrosis, and severe thirst constitute the most characteristic symptoms of initial pellagra, never being absent. The duration of this period is calculated by Zanetti and Gherardini to be from twenty to thirty days.

Pellagra conclamata: The pellagrous attack may end at this point without any further manifestation, and may perhaps leave doubt as to the identity of the syndrome, but this is rarely the case. It is generally at this time that the appearing erythema confirms the diagnosis.

The Erythema: Although there are cases of pellagra without erythema, still this is the most characteristic sign of the disease. The erythema, symmetrical in distribution, is usually preceded and accompanied by itching and swelling in the affected parts, and with the erythema there is a recrudescence of the various disturbances already mentioned. Although it may appear in autumn, still the season of the pellagrous erythema is springtime, between the middle of February and the end of May, as soon as the sun's rays become warm. It develops during the summer and gradually disappears at the end of autumn. All the unprotected parts may present it, so that while it is always visible at the beginning, on the arms and hands, it may later extend to the neck, upper part of the chest, the feet and legs, according to the calling of the patient and his way of dressing. On the arms and legs it begins on the extensor surfaces, later involving the flexor, but never the palmar and plantar regions. Its development on parts of the skin unprotected by the clothing clearly shows that the actinic rays of the sunlight play the greatest part in its development. The erythema begins with a very well marked puffiness and redness of the skin, generally on the back of the hands, followed by a burning and itching sensation. The redness and swelling disappear at the finger's pressure, but return as soon as the finger is taken away. Often the redness is followed by blisters (wet pellagra) very much resembling those of a burn. Later the blisters dry up, the skin cracks, and drops off in scales.* Later on the skin assumes a brownish color and the pigmentation remains some time after the first attack. If others follow, the skin becomes thickened, assuming a yellowish, or old brownish, color, becoming hard and rough and losing its elasticity, the natural folds becoming deeper. The skin is then hard, thick, dry, rough, and exfoliated. In the more advanced stages the skin becomes atrophic, thin, losing its elasticity, showing whitish streaks like the *striæ gravidarum*.

There is little or no elevation of temperature. The symptoms relating to the nervous system increase in intensity, particularly the vertigo, and the various alterations of the sensibility, pyrosis, burning sensation, and itching. The disturbances of sensibility become intolerable. They are described by the patient as an intense burning in the plantar and palmar regions, which feel as if they were set afire. There are neuralgic pains, occipital headaches, muscular cramps, and pronounced burning feeling on micturition, often accompanied by ischuria. Common symptoms are loss of energy and bulimia not proportionate to the loss of strength. Loss of memory and irritability are the main psychic symptoms. Of some interest is the development of the characteristic stomatitis. The mucous membrane of the mouth and the tongue assume a cardinal red color, with desquamation, aphthæ, and eruption, herpes-like around the lips. The tongue in the first period is, as a rule, thickly coated, the salivary secretion increases, while the patient loses oftentimes the power of gustatory differentiation. These symptoms last generally from the early spring until autumn, or from the early autumn until winter, increasing in intensity at each attack, while the general condition grows worse. The patient passes from one attack to another, so that the disease loses its intermittent character.

Second Period: The pathological disturbances in relation to the nervous system help in pointing out

Fig. 5.—American type of erythema. From "Symptomatology of Pellagra." (Dr. J. J. Watson.)

*"The skin of the back of the hands begins itching and burning, becomes slightly swollen and red, much resembling a light erysipelas. To this cutaneous phlogosis, lasting only a few days, is added the raising of the epidermis that sometimes forms bullæ, but generally dries up, and cracks, to drop off later on in scales." Fanzago: "Paralleli fra la pellagra e le altre malattie che più le rassomigliano," Padova, 1799.

the difference between the second and the third stage of the disease. A characteristic nervous triad appears on the scene, namely: (a) tonic and clonic convulsive accidents instead of the light spasmodic phenomena; (b) progressive weakness, particularly of the lower limbs, sometimes having the intensity of a real paralysis; (c) cerebral disturbances serious enough to constitute a real psychosis, melancholia, with anxiety that may end in dementia, persecutory ideas, suicidal tendencies, rarely maniacal attacks. There is always a general muscular weakness that may be accompanied by increased muscular tone with remarkable accentuation of the reflexes, which is largely voluntary; in fact, it disappears during sleep, or when the patient's attention is distracted. (Tonnini and Bonfigli.) These symptoms are more marked on the lower part of the body. The gait assumes a particular character, either paretic or paretospastic. The patient moves with small steps, his knees half bent, while the legs are spread apart to increase the sustaining base. In the third stage walking is possible only by the help of a cane or a person. The feet are lifted very little, or not at all. There may be a certain degree of ataxia or tremor. Both are more pronounced in the upper limbs. The tremor may extend to the head, and the tongue is always tremulous as in general paralysis.

During the second stage of pellagra the skin of

Fig. 6.—Pellagrous lesions in the spinal cord.

the parts affected by the erythema becomes thick, hard, rough, and brown, particularly on the back of the hands, where it assumes the appearance of the *pellis anserina* (goose skin). The desquamation persists during the remission of the symptoms in autumn, when the skin becomes hypertrophic and cracks easily. The gums are inflamed, bleeding easily, as in scurvy. The tongue loses its coating of the first stage, assuming the characteristic appearance of the "pellagrous," or "cardinal tongue," so called from its intense redness, being brilliant here and there, escoriated, particularly at the borders, and resembling the tongue of a typhoid fever or smallpox patient. It becomes smooth on the surface at touch, feeling like velvet. This sign is so peculiar to the disease that it can be taken as decisive in doubtful cases. One of the members of the permanent Commission on Pellagra in Italy, Professor Ballori, in using this criterion of diagnosis of cases in the hospital of San Spirito, of Rome (when the first cases appeared in the province of Rome, 1808), recommended its use to me, for it is so constant a symptom that the Commission used it as a diagnostic criterion in the judgment of doubtful cases.

The anorexia increases often to the point of sitophobia, favored by the increased difficulty of gastric digestion, due to the diminished sensitiveness and motility of the stomach, to the diminution of hydrochloric acid, which may be altogether absent, to the consequently increased amount of mucus, and to the organic acids of fermentation. The pellagrous diarrhea now displays its characteristics. It is unaccompanied by pain, although being very violent and often uncontrollable, strongly contributing to aggravate the condition of the general nutrition to the point of the extreme emaciation of the third stage. The urine is generally scanty, pale, alkaline, and of low specific gravity. Diminished is the percentage of urea, of the chlorides, and phosphates, and increased are the alkaline salts. These alterations persist even after the patient's diet is properly regulated and taken care of, thus showing that the power of assimilation is deeply disturbed.

Third Period: As I said before, the division of pellagra into stages is artificial. There is no new symptom in the third stage, but those already described become more aggravated. The patient is in a state of general cachexia, with the appearance and marantic expression of a case of "general progressive paralysis," particularly characterized by the diarrhea, which is in the foreground. The diarrhea becomes now colliquative, most offensive, and accompanied by spasmodic disturbances of the intestine and bladder, and by peritoneal sensibility beyond control. It is important now to notice that the parts once affected by the erythema assume during the last stage a brownish color, are smooth, dry, thin, and unelastic; the cellular subcutaneous tissues disappear, showing white cicatricial lines.

We have here the usual picture of a marantic case with loss of strength, muscular atrophy, anemia, and loss of resistance to intercurrent diseases. Tuberculosis of the lungs, pneumonia, or septicemia from decubitus (bed sores), heart weakness, pulmonary edema, or other causes end the scene.

Pellagrous Insanity: The alterations in the psychic sphere play an important rôle from the beginning of the disease, under the form of a very slight general depression, together with a slowing of the power of formation of ideas and lack of disposition to think and to act. These symptoms follow physical disturbances step by step, and while they increase with them, they also progressively decrease with the decrease of the pellagrous attacks, to return again upon the appearance of a new attack. In advanced cases they become more imposing in character, reaching the condition of a real psychosis parallel with the physical phenomena. Sometimes the psychosis becomes at once chronic and then progressively fatal.

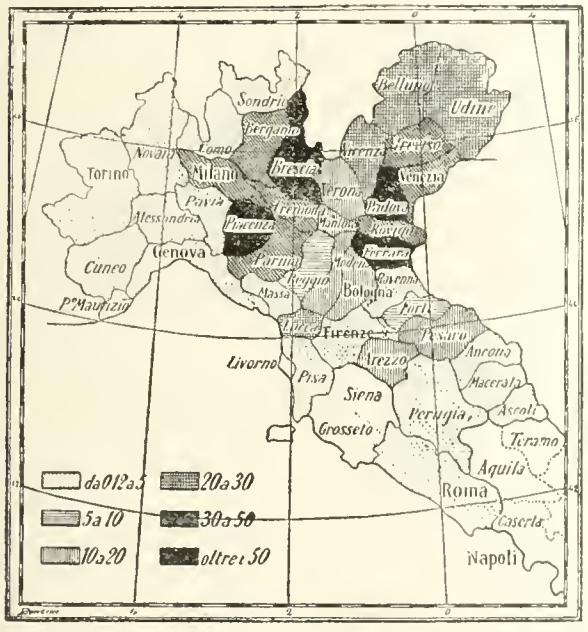
The pellagrous psychosis is quite characteristic. Common symptoms are: Serious depression, suicidal ideas, rarely distinct delusions or hallucinations, retarded thoughts, loss of insight, apprehension, morbid fears, especially fear of small things (micromania), some confusion and weakening of the memory, torpor without disorientation, but rarely complete stupor. In Italy, contrary to what seems to be a frequent occurrence in the asylums in America,* maniacal excitement and mental exaltation are rare, and rarer still are cases of systematic delirium which, when occurring, is associated with persecutory ideas.†

*"Pellagra, a Précis," by Passed Assistant Surgeon C. H. Lavinder, p. 16.

†The characteristic form of the psychosis is that of amentia that increases acutely, with loss of sense of place, loss of memory, confusion, hallucinations, and pares-

It is easy to trace some mental confusion and weakness of the memory that differentiates the mental conditions of the pellagrins from classical melancholia, mania, or paranoia. A very frequent manifestation is the tendency to effect suicide by drowning. Lombroso explained the prevalence of such a form of suicide by referring it to hydromania (morbid desire for water), the consequence of pyrosis. Bonfigli, instead, found the reason in the fact that much less energy and resolution are required for this form of suicide, together with the fact that the element for suicide is at hand in the rural districts. Where water is not at hand suicide is committed by hanging, or in other ways. There is often sitophobia (morbid aversion to food), due to the depressing condition and loss of energy caused by the pellagrous psychosis. Pellagrous insanity generally disappears in the first attacks with the disappearance of the physical symptoms, but later acquires the character of a permanent psychosis.

Typhoid Pellagra: It is often in the third stage that this fatal occurrence is noticed. The name is merely to point to the condition of the patient,



Distribution of pellagra in Italy in 1881 before the enforcement of preventive sanitary measures based on Lombroso's theory.

Distribution of pellagra in Italy in 1899 after the enforcement of preventive measures based on Lombroso's discovery.

which much resembles the classical description of typhoid fever cases. Although there are several theories to explain it—that which considers it as an expression of a common typhoid fever, as an intercurrent disease, to that of Lombroso, who regards it as a uremic, or ammoniacal, poisoning—it is now generally looked upon as nothing more or less than a sudden exacerbation of the morbid process.

The scene begins with a sudden sinking of the patient's condition and the appearance of accentuated hallucinations, mental confusion, general excitability, with disordered loquacity and carpology, often alternated by a real delirious condition, or par-

parthesias, with morbid impulses and delusions (Tanzi). It is often depressive, thus simulating melancholia, or it is accompanied by exaltation, thus simulating mania. As above stated, the pellagrous psychosis is intermittent, and if the patient falls again into his previous way of living the symptoms and reparable lesions of amentia are substituted by the symptoms and irreparable lesions of dementia (Tanzi). Pellagrins have never the lucidity of the non-delusional melancholic, lacking his errors, the coherence of the melancholic delusions. They show, if exalted, more fear than rage, more confusion than gayety (Tanzi).

tial stupor. The muscular system is almost in a condition of tonic contraction. Speech is drawling and tremulant, often inarticulate. Owing to the contraction of the muscles of the neck and back, the body may lie in a state that may go as far as opisthotonus. The face may present the usual anxious expression of stuporous conditions. Reflexes are exaggerated to clonic contractions. Characteristic are the profound prostration and the bed sores all over, the dry tongue, and the offensive breath. Fever is very high, especially at night. There is no splenic tumor, the spleen being often small. Roscola is lacking, too. The condition does not last over one or two weeks, and generally ends with the usual hypostatic pneumonia. As an expression of the altered trophism, about the fourth day, ulceration of the cornea appears in one and often in both eyes.

Although some authors, as we said, would not identify the pellagrous typhoid as a particular entity, yet it would be very difficult not to differentiate it from typhoid fever, or typhus. The sudden onset, the irregular and atypic fever (although with exacerbations), the rapid sinking of the patient, the short duration, the lack of splenic tumor and petechiæ, the general reaction, and expression of the patient that reminds one of a delirious, hallucinative syndrome, of an alcoholic with delirium tremens, rather than the stuporous condition of an ileotyphus, the general tetanic condition, the lack of the characteristic feces of typhoid fever, the rapid formation of decubitus the ulceration of the cornea, and the end constantly fatal, all these facts taken into consideration will avoid any possible error.

It is probable that pellagra is not as rare in the United States as has been generally supposed; probably, also, it is often overlooked or confused with other ailments, owing to the fact that the practitioner's attention has not, so far, been called to it, and that, appearing mostly in foreigners, the difficulty increases as a natural consequence of the difficulty in dealing with their language and the consequent inability to understand their ailments. The patients observed by me were all foreigners but one. In none of the cases in my private practice was

the disease even suspected before; one of them was referred to me by an American colleague to see if I could not get the patient deported by the Italian Consul, "as he was affected by neurasthenia with intestinal disorders" that made him unfit for the strenuous life here. Another case (a girl about 16) died of typhoid pellagra, and I did not succeed in persuading the physician in charge that it was not a case of typhoid fever, but one of pellagra at the last stage, with the usual complication of a galloping pulmonary tuberculosis. I also know of another case which was referred by an American physician to my friend Dr. Risicato because the patient could not speak English and the physician could not easily help him out in his gastrointestinal disturbances and neurasthenia. On examination, the case proved to be one of pellagra, and his family had all the degenerative characteristics often met with in such cases.

Since considerable attention is paid in recent times to investigations of pellagra in this country, I feel encouraged to report the history of the few cases observed by me in New York. Four belonged to the Cornell Clinic, one to the Health Department Clinic for Consumptives (Harlem Italian Clinic), and three to my private practice. Of the four cases seen at the Cornell Clinic, two were Italians, one an Austrian Jew, and one a Greek. The others were all Italian. Of all the cases, only one was a woman, the girl I have mentioned.

Case I.—B. L., male, age 24. From Sondrio Valtellina. One year in America. Always well, excepting for attacks of malaria contracted years ago while in the rice plantations. Well for three years before being taken ill with pellagra. About the end of December, 1905, while working in Florida, patient was attacked by weakness and diarrhea, attended by lack of energy. The diarrhea became severe and weakened him considerably. About April, 1906, the pallagrous erythema appeared on hands, neck, and feet; was very painful and associated with remarkable muscular weakness and salivation. Not being able to attend work, patient was brought to New York to his friends. On examination, he appeared emaciated; the pellagrous eruption more characteristic on hands than on neck and feet. It extended on the forearm up to the elbow. The patient had a marked melancholic appearance. Physical examination did not show any lesion of inner organs, outside of a discrete splenic tumor; the blood examination showed double generation of tertian malarial parasites. The patient's mental condition was such that he scarcely noticed the daily attacks of fever, which, having been rather mild, could have been referred to other causes. In fact, he came with a diagnosis of intestinal fever. The mucous membrane of the mouth was red and inflamed with tenacious, abundant saliva, the tongue was very smooth at touch, like velvet. Reflexes were exaggerated, small pupils; tenderness along the spinal column, urine scarce and alkaline. After prescribing quinine in accord with the sporulation of the two generations of tertian parasites, the elevation of temperature disappeared entirely, but the general condition did not improve. I secured for him passage back to Italy, for I did not believe that his general and social conditions would warrant keeping him here, hoping for improvement. Upon questioning the patient, I found that he used, both in Italy and America, a great deal of Indian corn as food, and was often made to drink cheap whiskey and liquors during his attacks of malaria and the first gastrointestinal disturbances.*

Case II.—L. S., male, aged 35 years. Italian laborer. Resident of America five years. He was well while working in Long Island for one year, then went to work in South Carolina, where conditions of shelter and food were very unfavorable, and where he contracted malaria. Under these conditions, patient says he had a relapse of gastrointestinal disturbances with pyrosis, loss of appetite, and diarrhea, symptoms which had already disturbed him slightly the last two months he was in Italy, but which had quickly disappeared while on the ocean and during his first year in America. The erythema on the hand appeared about March, 1907, with weakness, sialorrhea, and loss of ambition with it. When the eruption appeared patient came to New York for he suspected he had pellagra. He was referred to an American physician who did not understand the case and sent him to the Cornell clinic for advice. Here the patient gave a clear and full history of pellagra; the disease evidently began previous to his departure from Italy before the appearance of erythema, and had improved with better surroundings and food. As is common in the farming districts of Italy, Indian corn had been the base of his food in the form of "polenta." Physical examination did not show any lesion of the inner organs. The erythema, localized on arms and forearms, was brownish in color, with tendency to desquamation. The tongue and buccal mucosa were very red, the tongue being soft at touch; saliva abundant and tenacious. Patellar reflexes exaggerated, particularly on the right side; contracted pupils. Along the spinal column there was remarkable sensitiveness at touch and percussion. General appearance that of a very indifferent person. The patient stood the examination without appearing to have any interest in it.

Case III.—H. O., male, an Austrian Jew, aged 43 years. In America for two years. Had a very difficult life abroad and often poor food, the base of his feeding being Indian corn in various forms. For two months previous to coming to the clinic (March, 1907), patient had felt pain in both arms, particularly at the right side. The territory of the radial nerve was mostly affected. After one month the usual gastrointestinal disturbances appeared with a pronounced pyrosis and salivation and later the erythema, which was characteristic. At the time of examination patient's mental, as well as physical, capacities were greatly impaired. The physical examination showed a very poorly developed chest, sensitiveness on the spinal column, exaggerated reflexes; both pupils contracted; patient had vertigo during examination. The tongue was cardinal red and desquamated; the buccal mucosa inflamed. After the first examination the patient was lost sight of.

Case IV.—August 25, 1908. M. Z., a Greek, aged 37 years. About a year in America. On account of the language data were difficult to gather, but the patient was able to state that he noticed the erythema before leaving his country, where he was fed very poorly, mainly on Indian corn. The erythema had appeared during the spring before his leaving Greece, and was preceded by diarrhea, salivation, and weakness. These symptoms disappeared almost entirely

*Recent information from Italy tells me that this and the following case were there diagnosed as pellagra. I am also informed that both patients are doing very well.

during the autumn and winter following, only to come again in the spring, together with the erythema. General physical condition not much affected. Patient said that the syndrome was not as severe as the first time it appeared in Greece. He attributed this to better food. Suspecting pellagra, he came for advice as to the gastrointestinal disturbances, the general itching of the skin, the pain along the spinal column, and the persistent insomnia (provoked as he explained by the pyrosis). Physical examination: well built and nourished, lungs and heart normal, abdominal organs normal. Palpation of the spinal column revealed quite a sensitiveness, particularly of the lumbar regions on both sides. The tongue was red, flabby, and smooth on the surface at touch; buccal mucosa but slightly inflamed and desquamated, but abundant thick saliva. Pupils were both dilated, particularly the right one. At time of examination there was slight contraction to light. Reflexes were exaggerated, particularly the patellar; Romberg symptom decidedly present. The erythema was visible on hands and arms to the elbow, and on the neck was clearly limited at V with the angle on the sternum where the shirt was left open during work, brown in appearance and scaly, the skin dry correspondingly. There were slight traces of erythema on the dorsal regions of the feet, but not so pronounced as to attract the attention of the patient.

Case V.—Harlem Italian Clinic, No. 101. E. H., about 35 years of age, born in America and lived in New York all his life. He came to the clinic because of extensive tuberculous involvement of both lungs. He showed evident pellagrous erythema on hands, forearms, face, and feet. Patient stated that for about six years the erythema had appeared in the early spring. The first time it was preceded by pain, itching, and burning sensation. He had been ill with all the characteristic symptoms of the disease ever since the erythema appeared. His physical condition had not been very much affected excepting that he noticed a pronounced loss of ambition to attend to his work. The main symptoms beside the erythema were intestinal disturbances and salivation. The pulmonary tuberculosis dated back to about 1907. Physical examination showed his appearance to be that of a man much older than his real age; no lesions of the heart or abdominal organs, tongue of a characteristic cardinal red, desquamated, and smooth. His pupils were dilated, reflexes exaggerated, and tenderness was evident along the spinal column. There was a very extensive tuberculous lesion of both lungs. In this case it was impossible to trace the source of pellagra, for the patient had no more chance for eating Indian corn than would anyone else in New York. The man had been in several institutions for the treatment of pulmonary tuberculosis, but always at the end of winter and throughout the spring he would notice the appearance of the erythema on hands, neck, and arms, although his hands and feet were protected against the rigid weather by warm gloves and shoes.

Case VI.—P. C., male, a laborer, aged 30 years. He was referred to me in the autumn of 1907 as a case of chronic enteritis. Patient had never been ill until just two years before coming to America, when he contracted malaria while harvesting Indian corn. The spring following he was taken with diarrhea, salivation, and erythema on the hands, face, and neck. His case was diagnosed as pellagra, and upon proper treatment and improved surroundings and food he recovered entirely. He came to America fully one year after his recovery and was well for two years, but after working under very unfavorable conditions in different places in the South, especially in Florida, he became ill with malaria (mild tertian) for two months. Soon after and during the winter of 1907 he fell ill with cough, beginning to lose weight. In the spring the pellagra symptoms reappeared and he came to New York for advice. The main symptoms were diarrhea and gastric pyrosis. The erythema gave but little trouble, although being quite pronounced, and extending to his elbows. Mental depression not very pronounced; it was rather a lack of physical strength, following prolonged malarial attacks, of which he complained. Physical examination showed emaciated body, heart with anemic murmur at apex, lungs with signs of a probably healed tuberculous lesion at left apex, and upper lobe, at the lower border of which there were signs of recent infiltration; spleen still enlarged and hard. Pellagrous eruption on hands and forearms to the elbow, very pronounced; less on the neck; tongue inflamed and desquamated, saliva thick and abundant; dilated pupils, faint reaction to light, and eyes very sensitive to artificial light; exaggerated tendinous reflexes all over, tender to percussion of the spine and palpation of large nerves (sciatic and brachial). General condition was good; patient answered questions very intelligently, remembering particulars of past life very well, but was indifferent to the things and persons surrounding him, a fact often met with in the poor emigrant, who, after exhausting diseases, has decided to go back to his own country.

Case VII.—P. A., male, aged 27 years. Was sent to me for advice from Altoona, Pa., where he had been working in the coal mines. In America four years. His pellagra history was very much like that of Case VI, only that the symptoms began in America fully one year after his arrival, when he contracted malaria in Louisiana while working under very unfavorable and inhuman circumstances, under a system worse than peonage, poorly sheltered, and badly fed by the "boss," mainly on Indian corn and bad water. After suffering with malaria several months and still being underfed, he had diarrhea and was taken with attacks of severe weakness, which were often accompanied by painful feeling and sensation of weakness along the spinal column. These symptoms he attributed to malaria, but later the eruption came on the hands and feet and with it the sialorrhea and a progressive weakness that prevented him from working. These symptoms continued until autumn, when they disappeared and the patient improved. In the following spring they returned, although less severe; in the meanwhile he had changed his surroundings and was living in better circumstances; he improved again in autumn. The symptoms, however, returned in the spring, and the patient, recognizing the disease himself, came to New York for advice, and with the intention of returning to Italy. Examination showed patient fairly well nourished. His heart was normal; lungs with evident signs of dry pleuritis at the left base posteriorly; abdominal organs negative; pellagrous erythema on arms and legs quite extended. Buccal mucous membrane red and desquamated; thick saliva; tongue flabby and smooth; pupils not dilated, but not sensitive to light. Reflexes exaggerated all over; spinal column sensitive to pressure. Psychic condition very good. The patient was in good spirits and hoped to be cured by the native air and surroundings.

Case VIII.—C. M., girl of about 16 years. Her

ailment was diagnosed by me as pellagrous some two years before being taken ill with the final accident. She had shown symptoms of the malady ever since she was a child, before coming to America. There had been several cases of pellagra in her family abroad, the disease being very common in the village of her origin. Two years before death occurred I found her very emaciated and undeveloped for her age, being then about fourteen, and scarcely having the appearance of being ten years old. She clearly showed the triad of the malady; viz., erythema, digestive and nervous disturbances with psychic depression. She did not improve after coming to America, in spite of the better surroundings and food, particularly after the development of pulmonary tuberculosis (five years before death). In fact, it was just on account of this trouble that she was referred to me when I made the diagnosis of pellagra. Early in the summer of 1909, after suffering from the yearly recurrence of the pellagrous erythema, the patient's general condition suddenly became worse and within a week she was unable to leave the bed; high fever appeared and the gastrointestinal disturbances became more pronounced; increase of offensive movements, the breath fetid, tongue dry and cardinal red. Delirium with delusions soon appeared. At this moment I was called by her father in consultation. Patient was in a recumbent position and rigid, clearly showing muscular tremor on the face and limbs, the head retracted in a violent spastic condition; facial expression contracted to a suffering appearance that contrasted greatly with the stupefied indifference of the patient to questioning. Her legs were forcibly extended; feet in the position of plantar extension; carpology, as if following the delirious idea; and there were visible muscular tremor and slight ataxia; reflexes were exaggerated and clonic contraction of legs very pronounced. At the moment of examination patient was in profuse perspiration, and I learned she had been so, continuously, ever since her general condition became worse. She showed decubitus on the sacral region, between the knees, and on the scapulæ (she was in bed only seven days), corneal ulcer, quite severe, with protrusion of the iris in both eyes. Fever 104.3. From the physician in charge I learned that the patient had had fever ever since her condition became worse, that the stupefaction and delirium increased progressively, and that the corneal ulcers appeared on the third day she was in bed. The delirium was often very accentuated and the patient talked about a fire and her drowning in water; at times she would get obstreporous, but never had strength enough to jump from the bed or even to try to leave it. Gastrointestinal disturbances and vomiting were often uncontrollable. Physical examination showed in both lungs signs of diffuse hypostatic catarrh at bases. Both apices and right upper lobe showed no improvement of the old tubercular lesions and signs of cavity were in the right upper lobe. Heart was feverish; no splenic tumor nor roseola. In this case I found myself authorized to make a diagnosis of pellagrous typhoid on the basis of the existing pellagra of several years' duration, the sudden aggravation of the symptoms, the temperature, the absence of splenic tumor, absence of roseola, rapid appearance of the trophic disturbances (corneal ulcers and decubitus), and the general appearance of the patient, who rather gave the impression of the delirious syndrome with hallucinations of an alcoholic in delirium tremens than of the stupefied condition of a typhoid fever case. The patient, sinking rapidly, died ten days after my visit.

Important points on these cases are: 1. All of the cases but one were males, they being all foreign laborers. 2. Six out of eight were relapse cases. Only in one instance did the disease develop in New York, and this only can we call a real autocthonous case [No. 5]. 3. The use of damaged corn as a possible element in the etiology of these cases was found in six instances. In Case V, in which the disease developed in New York, the etiological element could not be found, nor could it reasonably be traced to the use of damaged corn; in this case the disease seemed to follow the description of cases studied in Europe, that is, of a disease of a very chronic character. 4. Case VIII showed the degenerative signs often to be found in the children of pellagrins. 5. All the cases had a very chronic development, and the erythema, too, never was as intense as it is generally described as being in the cases originating in the United States.

Conclusions.—(1) The essential cause of pellagra is still unknown.

(2) While we should follow with keen attention the new theories and the result of the researches on the etiology of pellagra conducted through new lines far apart from the theory well established by Lombroso, based on the use of Indian corn, and to its late modifications, we must still be cautious in casting aside the result of careful investigations (based on well established data coming to us from the history, statistics, epidemiology, and the clinic, as well as from the laboratory) to embrace in our enthusiasm mere suggestions of young observers.

(3) Sambon's and Alessandrini's theories that would tend to make of pellagra a disease of protozoal or parasitic nature, respectively, are yet to be considered as mere suggestions, rather than theories or even intuitions of a new theory.

As to the development in the United States, we may conclude that:

(1) Pellagra has been present in the United States in sporadic cases for a long time, but it has lately been diffused everywhere in the different States, assuming an epidemic character.

(2) In the United States the disease assumes a more acute course in contrast to its characteristics in Europe, and particularly in Italy, where, although very common, it has always the character of chronicity and the erythema never assumes the severe character which it does in the United States.

(3) The disease is relatively frequent among the well-to-do class in America, while in Europe it is essentially limited to the poor farming population.

A NEW VARIANT FOR VENTRAL HERNIOPLASTY.

By ARPAD G. GERSTER, M.D.,

NEW YORK.

SURGEON TO MOUNT SINAI HOSPITAL.

The principle of overlapping redundant aponeurotic material in ventral hernioplasty, thus adding to the thickening and strength of the reconstructed abdominal wall, has long since been advantageously employed in surgery. The main difficulty lay often in deciding what was or what was not fit material for lasting effect; what was to be excised and discarded as worthless, and what could be utilized in building up durable and resistant parietes. Filmy, extremely distended cicatricial membranes are naturally useless for any plastic work; but where the

cicatrix is massive, containing a goodly component of either old aponeurotic or newly formed fibrous elements, there the preservation and skilful use of such elements will tend to insure durability of the work of repair.

It is advisable not to proceed by rote or by haphazard, but, in view of the varying aspects of the local-

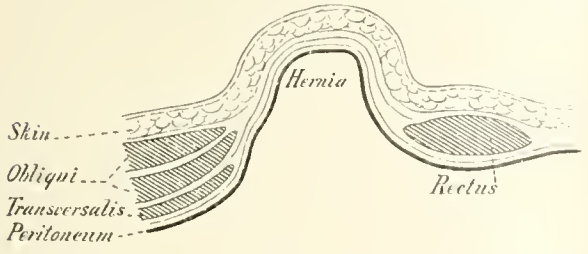


Fig. 1.

ity, size, and nature of the ventral hernia, to evolve a well planned line of action, utilizing every factor offered by the individual case in question. The following case may illustrate the principle:

Anthony R., butler, age 40, was admitted January 22, 1910, to Mt. Sinai Hospital with acute gangrenous perforative appendicitis, complicated with an ill-defined collection of fetid pus filling the right iliac fossa and Douglas's pouch. The appendix was deeply attached in the pelvis, and much care had to be exercised to mop out all the pus, and then to remove the brittle organ, filled with fecal matter, without further lacerating it, and thus dispersing its septic contents. To do this a Kammerer in-

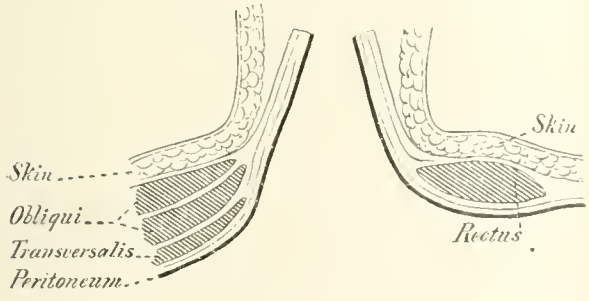

Fig. 2.

cision three inches long had been made, and the vessels and nerves traversing the field were not cut but drawn up and down out of the way by blunt retractors. Tube drainage of the pelvis was employed. The severe chill which had signalized the destruction of the appendix did not recur, and the patient made a smooth though slow recovery, and was discharged cured on May 5. He was readmitted October 18 with a large ventral hernia of the character of a wide diastasis between the right rectus and the musculo-aponeurotic limits of the oblique muscles, easily admitting the closed fist. Evidently there were no adhesions, as all the con-

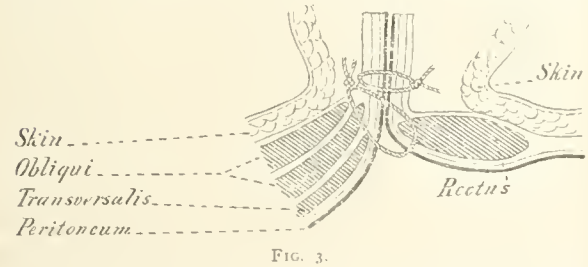

Fig. 3.

tents could be easily replaced. The distended cicatrix was, except in its center, underlaid by rather thick and tough material, hence it was decided not to excise all, but to utilize most of it. The dimensions of the hernia were 6 by 5 inches at the polar and equatorial diameters. On October 25 an oval portion of the central area was excised as far as it was found to be thin and anemic, then the hernial aperture in the parietes was dissected out until the aponeuroses of the rectus and the oblique came into view under the laterally detached skinflaps. After this seven sutures of quadruple stout chromic catgut were used to approximate and keep in contact the edge of the rectus and the musculo-aponeurotic line of the oblique muscles, the sutures passing through the sheath of the rectus (Fig. 3). Above this a second row of single catgut sutures was superimposed, widening the surfaces of contact. All this, especially the deeper row of sutures, had to be done with the exercise of a great deal of tension, fortunately very well borne by the tissues.

Thus we had formed two redundant, cockscomb-shaped flaps of aponeurosis and stout cicatricial material, that met with their peritoneal faces above the stout sutures. Of these the external one was twice scored, being thus scalloped into three digits, the inner one receiving three corresponding stabs, which would form three slits comfortably admitting the

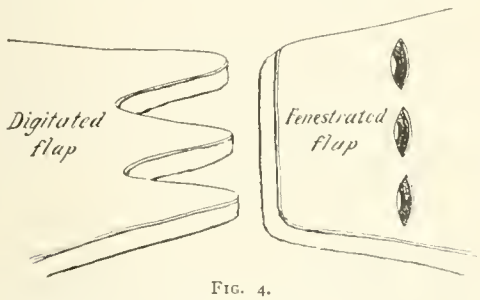

Fig. 4.

three fingerlike processes (Fig. 4). Each process having been passed through its corresponding fenestrum was sutured at its extreme end to the underlying fascia of the rectus; the inner square edge of the fenestrated flap being likewise sutured to the aponeurosis of the underlying external oblique muscle (Fig. 5) by six or seven stitches. Over all this the skin was brought together and sewed with interrupted fine silk sutures. A rather long rubber tube was brought out through a stab near the base of the external skinflap, draining the extensive hollow situated between the skin and the underlying parietes. No general or local disturbance followed, and, what was most gratifying and fortunate, no meteorism put the solidity of the sutures to a hazardous test. Large quantities of serum were brought to the surface by the rubber drain, which was left *in situ* for ten days. Even after this much serum escaped through the drainage hole. The wound healed throughout without a drop of pus, and the

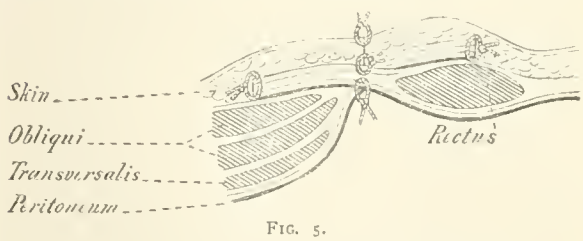

Fig. 5.

patient was discharged cured on November 20. It remains to be seen whether the cure will be permanent or not. On January 11, 1911, the patient was presented before the New York Surgical Society in good condition.

34 East Seventy-fifth Street.

HYPODERMIC INJECTIONS OF SALICYLATES IN RHEUMATISM.

By AUGUST SEIBERT, M.D.,

NEW YORK.

PROFESSOR OF PEDIATRICS, NEW YORK POLYCLINIC; VISITING PHYSICIAN, ST. FRANCIS' HOSPITAL.

That the salicylates often do not act promptly enough to prevent irreparable damage to the heart and more often are not thorough enough to destroy the less accessible rheumatic organisms in the body tissues when given by mouth is well known, aside of the fact that the disturbance of digestion and toxic symptoms frequently compel the physician to stop their use reluctantly. This dilemma prompted the author four years ago to introduce salicylate of soda into the blood current by hypodermic injection.

Mendel, Essen (*Therapeut. Monatschefte,* 1904, IV.) had given intravenous injections of an 18 per cent. solution of this drug in chronic rheumatic joint affections with good result. Obviously intravenous medication is not practicable in acute cases where the drug must be given at least twice in twenty-four hours.

My first attempts at hypodermic injection of salicylate of soda were made in the case of an otherwise healthy man of forty years, a private patient in the German Hospital, whose rheumatic left knee and right wrist joints had resisted the largest possible doses per mouth (up to thirty grains given six times daily) for two months. Baking in hot air and Bier's stagnation, tried during four weeks under the supervision of one of the attending surgeons, Dr. F. Torek, had given but negative results. Twelve c.c. of a 20 per cent. sterilized watery solution of fresh salicylate of soda were injected under the skin of the outer thigh twice daily. Although painful, the patient reported the first night without pain the next morning. Continued injections, without other medication, during the next two weeks succeeded in destroying the organisms lodging in the periarticular tissues, brought the temperature and pulse rate to the normal, and permitted passive and active movements, massage and electricity, to be used, so that a month after the beginning of the injections the patient could bend his knee to a right angle, walk with a cane, and write long letters. But some of the affected muscles had become atrophied during the three months of inflammation before the injections were resorted to, so that the patient had to resign his command as captain of one of the well known transatlantic liners. Earlier injections would certainly have prevented this.

In the next case, a Japanese private patient in St. Francis' Hospital, weighing 110 pounds, the left ankle and the right wrist joints had been in a state of marked rheumatic inflammation for two months. Twelve c.c. of a 20 per cent. salicylate of soda solution, injected twice daily for a week, once daily during the next, and three times during the third, resulted in complete recovery.

The next trials were made in three cases of severe rheumatic chorea; two of these were patients in St. Francis' Hospital, the third in private practice. Violent involuntary motions, marked mental affection (lacrymosity, etc.), thick speech and constant dribbling of saliva. Two had endocarditic murmurs, one slight albuminuria. Duration of illness from two to three and one-half months. Ages, 12, 15 and 16 years, respectively. All three had been on Fowler's solution for many weeks without result. The first effect of the injection, given in the two older ward patients (12 c.c. of the above-mentioned solution) was to start quite a commotion on account of the pain, but after the fourth injection the violent motions ceased, and after the twelfth injection all symptoms of chorea had disappeared with the mild fever and the albuminuria. Ten to fifteen grains of aspirin, given thrice daily during the next few weeks, prevented recurrence.

In the next private case, a lady of 35, who had been operated by Dr. Bodine on account of malignant breast tumors, and some months later suffered from daily recurring neuralgic pains in the lower limbs (suggesting the possibility of metastatic involvement of the spinal cord) the same injections were given once daily as a last resort to exclude the possibility of rheumatic infection, to the surprise of all concerned with good result. The first injection shortened the next neuralgic attack from four hours to thirty minutes, and the following six caused disappearance. In this case it occurred to me to add one-eighth grain of cocaine to the solution. This reduced the duration of the pain to two minutes. Although this was an improvement, the procedure invariably appeared somewhat brutal and therefore was not likely to become popular.

My experience with large hypodermic injections of the 20 per cent. camphorated oil during pneumonia (*Münch. med. Wochenschrift,* September 7, 1909), which are practically painless, suggested the mixing of salicylic acid with oil. Tests made in the laboratory of Mr. Otto Amend (of the firm of Eimer & Amend) showed that salicylic acid would dissolve in olive, cotton seed, or sesame oil in only five parts to one hundred. Such a solution would necessitate an injection of so large a volume as to make it impracticable. The amount of salicylate in a 5 per cent. solution, in 12 or 15 c.c., would be too small to be of value.

After many trials, Mr. John Seitz succeeded in producing a 10 per cent. salicylic acid solution in sesame oil by adding 5 per cent. of pure alcohol. When injected this solution caused the same amount of pain as the watery 20 per cent. salicylate of soda solution. While examining the condition of a highly nervous man of 30 years in the ward of St. Francis' Hospital, who had been admitted with fresh rheumatic arthritis, endocarditis, and hemorrhagic peliosis of the lower limbs, it occurred to me to first inject a small watery solution of one-eighth grain of cocaine under the skin in the spot where the salicylate solution was to be deposited; to wait until the subcutaneous tissue had been rendered anesthetic and then to inject the salicylate. This plan proved to be effective, for the 25 c.c. of the 10 per cent. salicylic acid in sesame oil, to which 20 per cent. of gum camphor had been added, were injected without pain.

This case had been selected to see how far one large injection would cause improvement, as his ailment had lasted but a few days. The man's temperature was normal in three hours, all pain (excepting a soreness at the point of injection) had left him the next day, and the hemorrhagic spots and the swelling of his joints had disappeared in a week. Only the one injection was given.

This experience proved that a salicylate solution could be injected hypodermically without discomfort to the patient and that a sufficiently large injection of salicylic acid or salicylate of soda could destroy the vitality and inhibit the pathogenic action of rheumatic organisms in the human body in a few hours without causing symptoms of salicylic poison-

ing. None of the injected patients presented symptoms of heart depression, ear-buzzing, or profuse sweats.

During the last year the following rules have been adhered to by the author: In *acute rheumatic infection* of joints, heart, pericardium, pleura, and central nervous system (chorea), 10 c.c. of a 20 per cent. sterilized solution of fresh *salicylate of soda* to 100 pounds of body weight are injected *fifteen minutes* after an appropriate cocaine solution has been injected under the same spot. If the injections are made earlier than this the solution will cause pain. This is repeated every twelve hours. In severe cases, with many localizations of the rheumatic process, the dose may be increased to 15 c.c. of the solution to 100 pounds of body weight. I consider it essential to the success of this treatment that the above doses be used. Smaller doses will be without effect.

The effect may be noticed within three hours after the first injection. Joint stiffness, pain, fever, and pulse rate diminish and the general feeling of the patient improves. If the injections are continued regularly every twelve hours the improvement also continues; if they are omitted for twenty-four hours in severe cases the symptoms will grow worse; but in milder cases the improvement may continue, proving that a sufficient amount of the salicylate had already been injected to destroy all rheumatic organisms in that case.

In *chronic* cases 10 c.c. to 100 pounds of body weight of the following oily solution are injected every twenty-four hours: acid salicylici, 10 grams; olei sesami, 80 grams; alcohol, pure, 5 grams; gum camphor, 5 grams. This mixture is sterilized before the alcohol is added, but must not be exposed to the air, as the alcohol will evaporate and the salicylic acid crystals will precipitate.

This 10 per cent. oily solution of salicylic acid acts better in *chronic* cases than the 20 per cent. watery solution of salicylate of soda, most likely because it is less quickly absorbed from the point of injection and less speedily eliminated by the kidneys. For the same reasons the 20 per cent. watery salicylate of soda solution is more suitable for *acute* cases where prompt and strong germicidal action is required.

The effect of the injection in *chronic* cases is noticed sooner where multiple localizations of the rheumatic process are present than where but one joint is affected. In the former, pain and stiffness usually improve after the first, in the latter, after the third injection.

The addition of camphor (5-20 per cent.) has been found beneficial in stimulating the heart, especially in peri- and endocarditic cases. The weaker the heart, the more camphor was given in the oil. Like in my experience in pneumonia patients, overstimulation or other toxic symptoms from the camphor were never seen, although as much as 45 grains of pure camphor have been injected in one injection, and this repeated daily for a week.

The entire absence of all the toxic symptoms which are sometimes seen when salicylates are given by mouth, is one of the pleasantest features of this method of treatment.

Technique.—A spot outside of the median line of the thigh is disinfected by a few drops of fresh iodine tincture. Through this, the sterilized cocain solution (⅛ grain in 30 drops) is injected *under* the skin. After waiting fully 15 minutes the salicylate solution may be injected, the skin being raised high up with the left hand, so that none of the solution is pressed into (instead of below) the skin, which might cause sloughing.

The watery solution must be boiled directly before the injecting; the salicylic oil remains sterile after the first boiling.

The small as well as the large syringe must be boiled directly before using. The large syringe must be entirely of glass (Luer) without rubber washers, which become brittle on coming in contact with oil. The standard 10 c.c. Luer syringe will hold 15 c.c. When injecting the oil a larger caliber needle is necessary, and the syringe must be carefully cleaned with ether after using, to remove all particles of the solution adhering to the barrel and piston and insure smooth gliding during the next injection.

Abscesses are due to faulty sterilization, and sloughing of the skin to faulty technique. The author has not seen either.

THE TREATMENT OF ACUTE MANIA.

By CHARLES P. NOBLE, M.D., Sc.D.,

PHILADELPHIA.

I WISH to present to the profession a new treatment of acute mania, based upon a theory of functional insanity, the nature of which, I believe I have worked out. This is that functional insanity, so called, is due to the degeneration of the protoplasm of the cortex cells, and of those of the pituitary ganglion, which degeneration I have called molecular degeneration—as it is the degeneration of the units, or the elements, of which the cells are made up, as shown by the difference in the reaction to staining agents in these cells as compared with normal cells. (Vide, "The Nature of Neurasthenia and Acute Insanity," by Charles P. Noble.)

The process whereby the molecular degeneration is produced is that of autointoxication, together with hypesecretion of pituitary and of thyroid extracts. The intoxication is the result of the increased metabolism brought about by hyperthyroidism. The thought is relatively aberrant and unvolitional, and the will is relatively exalted and is not under the control of the individual; he has, relatively, lost self-control, or, in other words, the power of inhibition.

It has been found that the principle and process are the same in both neurasthenia and in acute functional insanity. It is a question of degree, and not of kind. The irritation stage of neurasthenia may be termed chronic unvolitional irritability, or chronic involuntary anger. Mania is the same thing, exaggerated "an hundred fold." Anger is the obverse of righteous indignation; that is, the one is immoral and the other is moral. It is a disorder of the will, or the spirit, or the soul of man. The irritation stage of neurasthenia consists of unvolitional chronic irritation, or chronic anger. It manifests itself when the individual is acting, or doing, in outbursts of irritability, or of anger, which is relatively beyond the individual's control—relatively, he has lost the power of self-control, and his thought is aberrant, in that in the irritation stage he is optimistic and in the stage of depression he is pessimistic, although he is rational.

When the course of living—the environment—which has caused the neurasthenia is persisted in the degeneration of the cells becomes progressive, and their function becomes more and more morbid. The

reserve vital force in the cells is more and more exhausted, and the potential energy has about all become actual.

If now the individual continues to force himself to do his work the overworked, degenerated, and exhausted cells react violently, and there is an explosion, called mania.

The vicious circle consists of the following: Of too much work, increased metabolism, chronic autointoxication, irritability, and relative exhaustion of the will; increased secretion of pituitary extract, increased secretion of thyroidin, followed by increased and aberrant thought, and progressively increasing autointoxication.

The form of treatment which I have to suggest is that when mania first develops the subject shall be given a hypodermic of morphine sulphate—about one-third of a grain, repeated if necessary. This will temporarily quiet the patient, when he should be anesthetized with nitrous-oxide gas and oxygen. If this is administered properly the subject can be kept asleep without risk for an indefinite period. The colon should now be filled with, approximately, three quarts of normal salt solution, and at the same time hypodermoclysis should be employed—filling the subcutaneous connective tissues with, approximately, two quarts of normal salt solution.

If a suitable apparatus is employed, using three Y-tubes, four needles can be inserted at one time, and in this way the salt solution can be administered very promptly.

This process can be repeated from time to time, as the condition of the patient indicates. There can be no objection to the refilling of the colon every eight hours, and at first the hypodermoclysis may be employed once daily. After two or three days it is probably better to intermit the employment of the hypodermoclysis lest pressure necrosis of the connective tissues ensue.

The patient should be kept in a drowsy condition, or else asleep by means of the administration of hypnotics—sulphonal, trional, the bromides, morphine, hyoscine, etc.

The object of the treatment is to break the vicious circle—to put the will in abeyance, whereby no nerve force shall be set free in the pituitary gland, and cause the secretion of the extract, and thus in turn, as this extract shall fail to stimulate the thyroid gland, thyroidin will not be produced, and thus in turn it will fail to reach the cells in the cortex of the brain, and thus the aberration of the thought so characteristic of acute mania will not be produced, and hence this thought, this judgment, or this form of nerve force, will not set free that form of nerve activity which is called the will; hence the will will no longer be accelerated, but, on the contrary, as the patient should be kept in a drowsy condition, or else actually asleep, he will be will-less.

If this treatment shall be kept up for several days the kidneys will be enabled to get rid of the accumulated toxins and the patient will therefore become rational. The condition of acute mania will have been reduced to the period of convalescence from the irritation stage of neurasthenia.

It is not my purpose in this communication to supply the data in my possession. It is my desire to present this method of treatment to those who are engaged in treating the insane, in order that they may try it for themselves. I can state that the form of treatment, if used with reasonable discretion, is without inherent danger.

UNILATERAL CHYLURIA CAUSED BY THE FILARIA SANGUINIS HOMINIS TREATED BY 606.*

By PAUL M. PILCHER, M.D.,

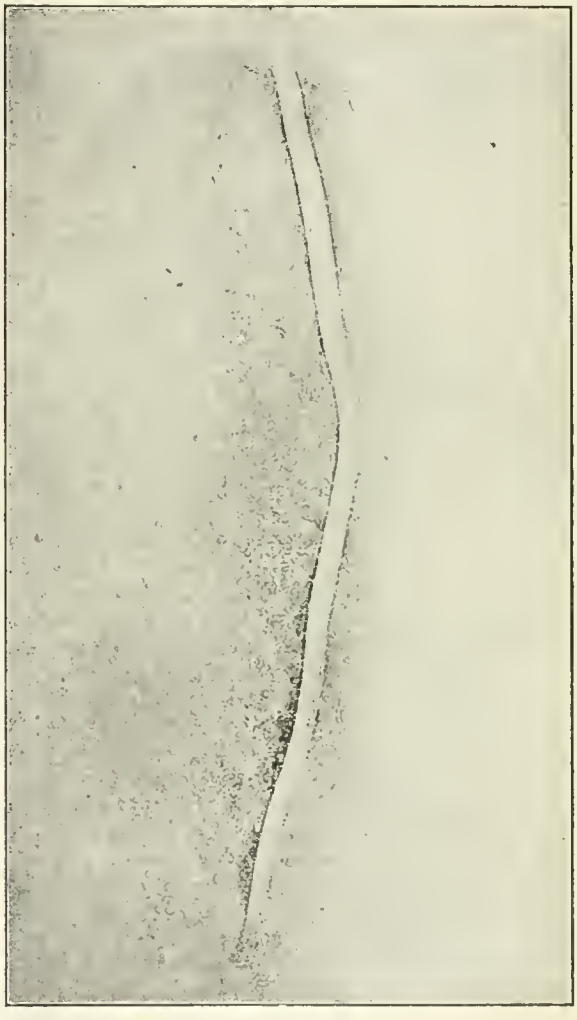
AND

JAMES T. PILCHER, M.D.,

BROOKLYN, NEW YORK.

We wish to present this preliminary report of a case of *Filaria sanguinis hominis* presenting the symptoms of unilateral chyluria, treated by an injection of 606.

The patient, referred to us by Dr. H. F. Williams, was a female, aged 35, white, married; was a native of British Guinea, where she resided until



Photomicrograph of filariæ recovered in smear taken at 12:30 midnight.

five years ago, when she came to Brooklyn. Seven months ago (*i.e.* after an interval of four years from the time she left the tropics), without other subjective symptoms, she began passing milky urine. This has continued up to the present time, varying only in degree, the only complaint being the distress consequent to the passing per urethram of the large curds which formed at times in the bladder.

On examination of many hundred smears taken hourly during succeeding nights, filariæ were found to be present only in those taken between 11:30

*Read before the American Urological Association, New York, February 1, 1911, and the Brooklyn Gynecological Society, February 3, 1911.

P.M and 12:30 A.M.; the blood during the day was negative, nor were any filariæ to be found in the chylous urine; blood was, however, constantly found. A photomicrograph of the form obtained in these night smears is shown herewith.

By cystoscopic examination and ureteral catheterism we determined the absence of lymphatic varices in the bladder, a normal functional reaction to phenolsulphonephthalein in both kidneys, and further, that the chylous urine was being secreted from the left ureter only.

Six-tenths gram of 606 was administered hypodermatically for us by Dr. James Winfield. The reaction was evidenced only by a rather severe headache and a general sensation of tingling, especially in the fingers, lasting two days. After this injection the urine remained unchanged for the first 24 hours; during the succeeding 48 hours the urine became perfectly clear for the first time since the inception of the complaint, seven months before. Suddenly, however, from the sixty-eighth to the seventy-second hour, the urine became markedly chylous and contained large numbers of seemingly dead filariæ of both embryonic and adult forms, the latter so large as not to need a microscope for demonstration, resembling white threads in appearance; after the seventy-second hour the turbidity ceased until at the time of discharge only an intermittent opacity was present, and no filariæ were demonstrable.

Blood smears taken continuously from the twenty-fourth hour after injection with 606 to time of discharge; that is, for one week, were all negative as far as finding any filariæ was concerned, whereas before the injection there was no trouble in finding the filariæ in the midnight specimens.

We wish to submit this as a preliminary report only, on this method of treatment of this hitherto untreatable infection, with the hope that it may stimulate more conclusive opinions from those who meet so many of these cases.

One interesting observation was that with the disappearance of so many filariæ from the blood, whether lifeless or not, there was no marked shock or reaction on the part of the patient.

145 Gates Avenue.

ARTIFICIAL MUSCLES IN THE EARLY TREATMENT OF INFANTILE PARALYSIS: A NEW METHOD.

By ROLAND O. MEISENBACH, M.D.,

BUFFALO, N. Y.

The prevention of deformity in infantile paralysis should be undertaken as soon as the febrile and acute symptoms have subsided. The teachings until recently have not emphasized this point; there has been a tendency to wait in the hope that many of the affected muscles would regain their power. That some of these do regain their power is the rule, but the period in which they regain their power is problematic, extending over weeks and months. During this waiting time much valuable opportunity for preventing deformity is lost, even though massage and electricity are employed. The process of restoration is slow and inadequate to overcome the contractions of the unaffected muscles which are rapid. This fact is amply verified by the many cases of deformity which are met with and which have had electricity and massage.

Electricity and massage may or may not be valuable, but are not sufficient to prevent deformity by themselves. This is especially true when the foot, knee, or hand are involved. Orthopedic treatment should be instituted early—this does not necessarily mean that heavy braces should be applied. In the early stage such braces may defeat their own purpose. Steel braces are most valuable after it is evident that the paralyzed muscles will not regain, and preparatory to tendon transference. The recent work of Flexner, Lewis, Sachs, and others has suggested that the period of waiting before tendon transference is undertaken should not be eighteen months or over, as has been the custom, but at a much shorter period after the acute attack. If early orthopedic measures are instituted tendon transference will be even more successful in the future than in the past.

Artificial Rubber Muscles Taking the Place of Paralyzed or Weak Muscles.—For the past year I have been treating many of my cases of weak feet occurring in children and young adults, cases in which rigid apparatus was counterindicated by means of reinforcing the weak and flabby tibialis postiacus with a rubber muscle especially constructed for the particular case. Also in cases of talipes-equino-varus and valgus, this substitution as an aid to the weakened muscles was made. It was surprising to note in these cases how quickly the muscles strengthened. The rationale of this treatment is apparent—the rubber muscles simulating the normal muscular activity as a constant force. In cases of weak feet exercise alone is not adequate, from the fact that we are attempting to strengthen muscles fifteen minutes in the morning and fifteen minutes at night, as the case may be, and during the remainder of the day the muscles are being overworked and are again subjected to the weakening cause. In infantile paralysis, the same muscular inability occurs, only in a more marked degree, therefore, this method suggested itself to me in the early treatment of infantile paralysis and has been used with success in selected cases.

The Artificial Muscle.—For the construction of artificial muscles an ordinary rubber dam is used, which can be procured at any rubber store. The thickness of the rubber varies, but its strength should be in proportion to the work of the muscles which it reinforces. The dam is cut into strips from 2 to 4 cm. in width and from 12 to 24 cm. in length. At each end of these strips pieces of zinc-oxide adhesive plaster are attached, which grip the ends of the rubber to the extent of about 4 cm. and extends about 10 to 12 cm. beyond the rubber. The adhesive plaster coming in contact with the rubber should grasp the rubber on all sides and should be clasped in a vise or compressed with a mallet, so as to prevent breaking away when tension is applied. If necessary the adhesive may be slightly heated over a flame.

Method of Application.—The method is chiefly applicable to the ankle, the knee, the wrist, and shoulder joints. One end of the artificial muscle is applied over a joint corresponding approximately to the origin of the muscle and the other at the insertion of the muscle. For instance, in a simple case of infantile paralysis involving the peronei group, one end of the rubber muscle is applied on the outer border of the foot, passing over the cuboid, and the other end applied on the outer side of leg, half way between the ankle and the knee. When the tibialis postiacus is involved its origin and insertion is a guide to the application of its artificial muscle. In every instance the

rubber muscle is applied as taut as the treatment warrants. It might here be said that very little tension is necessary if the limb is held in a corrected position at the time of application. When these muscles are applied to the wrist or other joints, or when more than one muscle is applied to the same joints, the adhesive strips may be cut according to the ingenuity of the surgeon. In many cases instead of a straight piece, the adhesive plaster cut in the shape of a Y will give a better grip.

Conclusions.—1. By the use of artificial muscles the lost power may be supplied temporarily until the paralyzed muscles have recovered.

2. The force exerted by them simulates the normal better than any other method.

3. Contractures of opposing groups may be prevented.

4. The rubber over the affected muscles causes a local stimulation which is noted by active hyperemia and perspiration of the skin beneath the artificial muscle.

5. Its use does not immobolize the joint, nor does it interfere with other prescribed treatment, namely, passive motion, massage, or electrical contractions.

6. Its efficiency is continuous and its simplicity does not interfere with the clothing or bathing. It is not intended to be used in advanced cases after the contractions have taken place.

THE CLIMATIC INDICATIONS OF EGYPT IN OTOLOGY AND LARYNGOLOGY.

By DR. GOLDMANN,

CAIRO, EGYPT.

Thanks to the public security associated with the English occupation of Egypt, this country is becoming more and more popular for tourists. It furnishes the most magnificent of ancient monuments belonging to the first and following epochs of art with the picturesqueness of Oriental life, and a unique winter climate. It is for this reason that the number of visiting invalids increases every year, especially those suffering from diseases of the kidney, rheumatism, gout, and diseases of the lungs. That it also deserves to be considered by the otolaryngologist I wish to explain in the following observations which I have made during the past two and a half years:

With the exception of the coast of the Mediterranean Egypt has, in the east and west, a pronounced desert climate, and in the interior a subtropical climate. The air is dry, the sky is clear and not very cloudy.*

The mean daily temperature in the months of December, January, and February amounts approximately to that of the last two-thirds of May; and to that of September in Frankfort on the Main, or in Berlin. In addition to this, the diurnal variability being very slight, the invalid is spared the frequent and dangerous changes of temperature so characteristic of Europe. The daily cooling after sunset is so regular that one may be prepared for it.†

*During the winter months cloudiness of the atmosphere attains nearly 50 per cent. of the maximum. In Berlin during the summer months it is 57 per cent. (Engel Bey: "Das Winterklima Egyptens"). The duration of sunshine at Helouan (half an hour's ride from Cairo), is four to six hours more than that of Davos, which is reputed for its prolonged sunshine.

†The wearing of light colored clothes during the day is recommended as a means of resisting the intensity of the heat rays.

Equal to the intensity of the heat rays is that of the chemical rays; for instance, during the spring equinox in Cairo their intensity is twice as great as that in Heidelberg. To this circumstance may be attributed the fact that among the colonized Europeans, but more among the native and black population, lupus of the skin and of the mucous membrane is a rarity; this is corroborated by the dermatologists of this locality. For this reason I believe that Egypt will be noted for the cure of lupus. On account of the low humidity the number of rainy days is small, so that chilling, especially of the feet, so frequent in Central Europe, rarely occurs. The dryness of the atmosphere facilitates the absorption of the perspiration and the excretion of the water through respiration.

Probably to its unique climate with its strong bactericidal sun Egypt has to be grateful for the fact that the influenza epidemics in the winter of 1889, 1890, and 1892 attacked only a relatively small part of the population. These epidemics interest the rhinologist by virtue of the paucity of nasal and aural complications, and of symptoms referable to the accessory sinuses of the nose.*

In special groups of diseases the beneficial effects of the winter climate of Egypt, from the viewpoint of the otolarnygologist, are not so easily understood. Politzer thinks that for secretory catarrhs as for chronic adhesive processes of the ear a stay in the southern climate is indicated. I only add that Egypt fulfills this indication from the etiological viewpoint, and may remove the susceptibility of catching cold and relapsing nasal affections or diatheses as scrofula, tuberculosis, gout, rheumatism, or syphilis.

Körner has lately pointed out in the general treatment of chronic otitis the importance of residence in a southern climate; Egypt in the winter meets this indication. Here the patient has the advantage daily of many hours of sunlight without the disadvantage of lying down, and also of the exercise cures in the health resorts of Central Europe. He is protected against catching cold by the increased activity of the skin as an organ of excretion. Acute exacerbations of Eustachian catarrh are avoided.

In addition must be mentioned the favorable influence of dryness of air, which, as favoring the

*Engel Bey has informed me that he has also observed cases of accessory sinus involvement. From February 20 to March 20, 1910, I had the opportunity of observing an epidemic of acute infections of the nose, throat, middle-ear, and bronchial tubes, caused by various bacteria. The otitis occurred in patients who had already had aural affections. The epidemic began with many days of increased atmospheric pressure and a warm south wind (*chamsin*). The latter is a desert wind which, as it passes over the cultivated land, takes up moisture and becomes a factor favorable for the development of infectious diseases. Within five days this wind changed to a markedly cold north wind with the same rapid rise of the barometer. I have been able to confirm the observation already made by other physicians in Cairo that morbidity and mortality are greatest during the season of the south winds. By analogy it may be noted that in Europe the incidence of catching cold and of infectious illness is greatest after a period of prolonged warm and dry weather, when, with a cooling of the atmosphere and the precipitation of the moisture, the atmospheric pressure rises. The increased morbidity is to be attributed partly to the increased predisposition of the individual resulting from the thermic relaxation and turgescence, and the change of clothing. One of the best environments for the avoidance of infections is afforded by the dry desert places of Egypt, rich in sunshine and oxygen. Of these may be specially mentionel Helouan and the new and growing desert suburbs of Cairo and Heliopolis.

cure of suppurations of the middle-ear, is a characteristic belonging only to Egypt. Not otherwise can I explain, among many others, the following cases, which were treated in Europe for some time without success, and which in this climate were unexpectedly and quickly cured mostly by means of simple dry air treatment:

Case I.—J. B., a German brewer, forty-nine years old, suffered since the age of seven years from chronic middle-ear suppuration following scarlet fever, with difficulty of hearing and violent roaring in both ears day and night; he has had diverse forms of treatment in France, Germany, and South America without success. On February 6 his condition was as follows: There was a profuse purulent discharge from both ears. In the left ear only one-third of the drum membrane was present, the handle of the malleus was thickened and fixed to the promontory. The mucous membrane of the tympanum was covered with granulations. The long process of the incus was missing. In the right ear the drum membrane presented the same appearance as in the left. The long process of the incus was present. Test of hearing: Left, whispering voice, 3 meters; right, 0.20 meter. Audition for the lower parts of the tone scale was weakened. The treatment consisted of the use of peroxide of hydrogen, which had already been employed, and simple cleaning with cotton wool. Boric acid was discarded after one application because of the strong reaction manifested in the form of purulent discharge and a louder noise. After eight days' treatment the ears were dry. A relapse occurred the following week after a coryza. March 3 both ears were dry; April 1 the roaring in the left ear disappeared, and in the right soon afterward. By massage with the pressure probe of Lucae and the air douche, continued until April 17, the right ear was able to distinguish the whispering voice at 3 meters, and the left ear at 5 meters.

Case II.—M. L., student at the Agricultural High School in H., 23 years old, suffered since 1905 from suppuration in the right ear, which suddenly came on without any pain and was diagnosed as tuberculous. Shortly afterward he had hemoptysis, which was cured very quickly. Courses of treatment at diverse places, finally in Davos, succeeded only to the extent of changing the purulent discharge to a more mucous secretion. For a fortnight he stayed in Helouan, at the end of which time he noticed an essential diminution of discharge. Treatment: Simply drytip; the third day the ear was dry and remained so during the next ten days until his departure.

Case III.—Mr. B., manager of a local hotel, suffered since childhood from disease of the left ear, which would discharge from time to time; his hearing was poor. For four months the ear dicharged continually. His condition on October 5, 1909, was as follows: The left ear presented a bad smelling and dirty colored suppuration, with particles of choleosteatoma. The drum showed a border perforation in the posterior upper quadrant, with absence of the long process of the incus. Whispering voice, left ½ meter; right 6 meters. Tone hearing chiefly weakened at the lower threshold. For the pain only syringe with water was advised. On October 9 the ear was dry and remained so, in spite of the application of cottonwool and silver for the amelioration of hearing. Hearing test on October 15: Whispering voice, left, 1.4 to 5 meters (the numbers 100 and 5); right, 6 meters.

Case IV.—A Coptic girl, aged 13 years, suffered since the age of eight years from double middle-ear suppuration. January 10, 1909, her condition was as follows: A drum defect on both sides, involving the under half, which had smooth borders; the tympanum was granulating, had little secretion, which was bad smelling. Dry treatment with boric acid was employed. Permanent healing occurred in five days.

Whether spontaneous healing of middle-ear suppurations is more often found here than in Europe is a subject upon which I can not now form an opinion.

To these cases I can add a series of others, which were all unexpectedly and quickly cured. Only exceptionally in the case of caries of the ossicles or of the petrous bone, or cholesteatoma of a greater degree, or severely granulating middle-ear cavity, the healing required a longer period of conservative or operative treatment. In regard to the otosclerosis, the spongy transformation of the labyrinth capsule perhaps indicates a favorable influence of the climate. In spite of this, we can expect its occurrence to a certain degree, in view of its etiology (cold by Liebermann and Hartmann, syphilis by Habermann and Gradenigo, anemia by Walb, gout by Buck and others).

But more interesting is the fact that sclerosis is in Egypt among Europeans, even more than among the native Arabic population, a much rarer disease than in Europe. Among my forty-seven cases of progressive deterioration of hearing without preceding suppuration and exclusive of nervous affections, of which sixteen occurred in Europeans and thirty-one in Arabs, I could with certainty diagnosticate thirty-nine cases as chronic adhesive otitis media. Of this condition the following signs were diagnostic: (1) the state of the drum (position and mobility), and of the tube (diminished or reduced permeability), and (2) an extraordinary amelioration of hearing through the use of the air douche and the pneumatic pressure probe massage. Among the remaining eight cases of sclerosis were six Europeans and two Arabs. Among the Europeans were a German hospital nurse who had brought her illness from Europe; a Greek and a Turkish woman; a brother and sister of Jewish nationality, the latter very anemic and showing the effects of privation, and a German geometrician with syphilis in his anamnesis. Although the absolute number of my notes is insignificant, I think that the former numbers are not accidental. If the proportion of the European to the Arabic scleroses is as six is to one this explains that the illness is imported; the disproportion is also explained in other ways: Psychic, nervous, and physical causes arising from strange conditions of livelihood, and the enervating and anematizing effect of the long Egyptian summer (my patients include the less favored class, which cannot permit itself the expense of the summer stay in Europe) are active causes for the following reasons. Among the Arabic population syphilis is frequent and runs a severer course than among the Europeans; refrigeration is surely more frequent because the cold of winter is felt by them much more than by the Europeans; the same anemic states are present in the women shut up in houses. Nevertheless, the followers of Islam have in their religion and habits, in their rustic or more patriarchal way of living, and in the custom of marrying young, in addition to their strong constitutions, a sufficient counteraction for

the damages resulting from the overindulgence in tobacco and coffee and the stress of the commercial life and summer's heat.

In the introduction I have referred to the favorable conditions of the Egyptian winter climate in reference to the prophylaxis of acute nasal affections, also their quicker course, due to the higher daily temperature, which causes a derivative action through the skin. I have also referred to the relative dryness of the air. This circumstance may account for the infrequency of coryza, and of acute infectious diseases, of which not only influenza, but also measles and scarlet fever, are here less prevalent than in Europe.

It can be stated that the number of acute affections of the accessory cavities is relatively very low. For the still more striking rarity of chronic diseases of the accessory cavities I think we may see a sufficient reason in the fact just mentioned, because not only the rarity but also the more rapid course of the acute affections of the nasal cavity conserve the ciliated epithelium of the sinus, so important for the elimination of secretion.

I have been able to observe only fifteen cases of sinus suppuration, among which were ten Europeans, of whom five imported the disease. Of the five cases in Arabs there were four suppurations of the ethmoid bone, of which one was a posterior form, perhaps caused by marked adenoid vegetations. For chronic rhinitis Heymann praises the high climate of Davos; for the reasons already noted Egypt fulfills this indication better.

Politzer states that otosclerosis is frequently united with ozena. In agreement with this remark I find sclerosis in combination with ozena of postoperative and syphilitic origin, but only a few cases of genuine ozena, in spite of the prevalence of syphilis, diphtheria, and measles, which are probably all of etiological moment. Practically only one infectious disease, namely, scarlet fever, is known in Egypt. Further, one important cause, chronic inflammation of the mucous membrane through repeated attacks of coryza with consecutive atrophy, causes seeming accessory cavity suppurations to pass for ozena. Other causes are the remarkable chemical and mechanical air mixtures indoors and out of doors of the boarding and working rooms, which here are mostly under roof, or in not quite sufficiently ventilated buildings. In spite of this, I consider the healthy and strong constitution of the Arab as an important preventive against the occurrence of ozena, particularly since this is to be looked upon as a constitutional disease.

The hypertrophy of the adenoid vegetations is here decisively more rare and does not reach the dimensions which we find it attains in Europe, even in little children. Besides, enlarged tonsils are also rare. I think this is to be attributed to the relative rarity of acute inflammations of the nose and the nasopharynx. If Chiari recommends a stay in the South for the chronic inflammations of the throat and the nasopharynx, I should like to agree to this with the reservation that in every case the etiology of the affection, first in reference to the state of the nose, is sufficiently marked. Primary inflammation, as it occurs in anemic or feeble individuals with torpid metabolism as the result of thermic irritations, finds here the best conditions of cure, the excessive number of secondary affections responding to the extent that local treatment also is employed.

Egypt is better esteemed by the laryngologist in the restricted sense. For chronic catarrhs of the larynx and the deeper air passages, and for the disposition to these, it affords without doubt the best climate. The hoarse patients in my practice were cases with serious organic changes (syphilis, tuberculosis, partial or total recurrent paralysis), or with pulmonary tuberculosis appearing under the mask of an affection of the larynx. Chronic catarrhs of the larynx I have not yet seen here. The clear, loud voices of the Arabs and resident Europeans, which impress the stranger, make my negative observation comprehensible.

The sufferer from tuberculosis of the larynx finds here, in addition to the best known favorable environment for the general state of the tuberculous and feverish, the best protection against the rigors of the European winter, which he does not escape even in the health resorts of the Riveria, in Genferlake, and in Southern Tyrol. The patient who is in need of a rest cure can remain here without the warm clothes necessary in other places, which hinder the action of the skin, which is important both for the lungs and for the general metabolism. To a certain extent efficacious, and for the patient the most agreeable, local treatment with direct sunlight can here be carried out better than in any other health resort.

Without counting the cases known to me of pulmonary tuberculosis in Europeans which were cured here, one notes that they are able to work in unhygienic surroundings, often in Arabic quarters. I had the opportunity of seeing one consumptive with a most serious laryngeal tuberculosis with extensive ulcerations on the much thickened, inflamed, and rigid epiglottis, with perichondritis of the arytenoid cartilages, with strong narrowing of the glottis, and with many ulcerations and granulations of the vocal cords, and complete inability to eat and almost complete inability to drink; with strong and continued fever—in other words, a hopeless consumptive. He had come here in the beginning of February with the expectation of benefiting by the desert climate of the suburbs of Cairo, so as to be able soon after to open a little shop in Cairo and to take care of it, a fact which I would not consider possible in any other place.

The months of November to April are regarded as the most salutary months in Egypt. In the case of diseases of the lungs, larynx, nose, and ear, with the exception of otosclerosis, in which higher temperatures are not favorable, one may extend the season from October to May.

Functions of the Thymus.—E. Weill presents a study of the functions of the thymus in which he shows that it is not an exclusively lymphoid organ, and that in all its history, physiological and pathological, it presents differences from the lymphoid glands which include the role of the epithelial elements. It arises from an invagination of the layers of the entoderm at the evel of the third brachial cleft. From the beginning of the fourth month of intrauterine life until the fourth year of life its function is active; then atrophy takes place. At birth it is in great part a lymphoid organ with a distinct covering and a central reticulum filled with leucocytes. Its structure resembles that of the bone marrow. There is a true balance between the development of the lymphoid and the epithelial elements. Injection of the thymus extract causes fall of blood pressure, as does that of the lymphatic glands. But it differs widely from them in its chemical composition. Removal of the thymus in young animals causes at first obesity and a state of edema, later cachexia and atrophy. Its effect is only temporary, showing that its function can be taken up by other organs, such as the genital organs, hypophysis, spleen, suprarenals and thyroid. —*Lyon Médical.*

MEDICAL RECORD.

New York, March 11, 1911.

THE PATHOLOGY OF PAROXYSMAL HEMOGLOBINURIA.

THE cause of this exceedingly rare condition has for a long time been veiled in obscurity. All that has been known regarding its etiology is that it attacks susceptible individuals following more or less complete exposure of the body to cold. Shortly after this exposure the dissolved hemoglobin appears in the urine and there are manifested the general symptoms of the disease, namely, a chill, a rise of temperature, general malaise, weakness, and prostration. The first suggestion as to the mechanism of the production of this condition was that furnished by the transfusion of blood for therapeutic purposes. Kentzler investigated the hemolytic action of foreign blood, and attributed it to the toxic action of the foreign proteid. It was subsequently found that not only the production of hemolysins follow the injection of hetrologous blood, but also autohemolysins are formed after the injection of blood from an animal of the same species.

Landsteines and Donath were the first to demonstrate the effect of cold in the production of autohemolysins in the test tube. Fro mtheir experiments they concluded that in the blood serum of hemoglobinuric individuals there are present autohemolysins that are set free by the action of toxins or of cold, and that as a result dissolve the red blood cells. In opposition to this view, Widal and Rostaine attributed the hemoglobinuric attack to the insufficiency of the antihemolysins.

The latest contribution to this subject, based upon an intensive study of two cases, is that furnished by L. Fejes and L. Kentzler in the *Zeitschrift für klinische Medizin*, Vol. 71, Nos. 3 to 6. Their investigations showed that in the blood serum of patients suffering from paroxysmal hemoglobinuria there are present autohemolysins, which under certain circumstances are capable of dissolving the red blood cells. During the periods of freedom from the attacks the red blood cells manifest an increased resistance with respect to the hemolytic substances. There is no evidence of any antilytic action. The authors are unable to assign any cause for paroxysmal hemoglobinuria. This is thought by many to be of luetic origin. At any rate the authors regard the presence of free lysin as a toxic manifestation which results either from the disturbance of the equilibrium between the autolysins and autoantigens formed following the disintegration of red blood cells or from the increased formation of lysin whose possibility has been demonstrated in animal experiments.

THE DIMINISHING BIRTH RATE.

PROF. CHARLES FRANKLIN EMERICK, writing in the *Popular Science Monthly*, January, 1911, asks if the diminishing birth rate is volitional and deals with the arguments for and against. Biologists assert that by the stress and strain of modern life the reproductive organs are undernourished and finally incapacitated from performing their special functions. Then a sterilizing process is continually going on in members of both sexes. The medical expert frequently supplements the evidence of the biologist and emphasizes the amount of involuntary sterility induced by sexual diseases. Owing to easier facilities for transportation, density of population, greater wealth and leisure, there are more promiscuous relations between the sexes than formerly. Also, the insuâcient wages of young women workers, who are unable by the labor of their hands to adorn themselves as young women like to adorn themselves, tend to promote immoral relations.

The economist, however, takes a very different view of the question. He takes issue with the biologist and medical expert on these counts and especially does he take exception to the statement that modern conditions of life, industrial and social, have rendered both men and women less productive, or at least, so much less productive as to account for the great fall of birth rate. His argument, in part, is somewhat in this wise, that if stress in excess of the ability of the body to appropriate nourishment impoverishes the reproductive organ, why is fecundity among the insufficiently nourished, clad and housed so great? The poor are notoriously the greatest begetters of offspring, and degenerates and alcoholics very often have large families. As for the contention that extreme brain activity is a factor of importance in sterility, he says that "the excessive use of the nervous system can neither cause its own undoing nor cause the under development or atrophy of the generative organs in any considerable portion of the population." In short, the economist regards the situation from a totally different standpoint and holds the view that large families are no longer desired, and that steps are taken to regulate the size of the family. Further than this, it is argued that since woman has, to a great extent, become self-supporting and is no longer almost wholly dependent on marriage, her will is more influential in determining not only the formation, but the admission of new members to the family. Men, too, are more averse to marriage and the responsibilities which it brings in its train than was formerly the case. Also, marriage is postponed later among women both from choice and necessity, which means fewer children and, as said before, measures are taken to limit the size of the family subsequent to marriage.

Prof. Emerick is rather on the side of the econo-

mists, and the conclusion of his able article is that "the diminishing birth rate is primarily volitional and that the various factors which make for voluntary sterility are of minor importance."

Of course, the arguments on either side are by no means conclusive. It is likely that steps are frequently taken to limit the size of families, but, on the other hand, it would be idle to entirely deny the importance of modern conditions of life, including venereal diseases, when discussing the question of the diminishing birth rate. Social and industrial conditions are factors which must be considered, even if they are not the most important.

DISINFECTION OF PLAGUE SHIPS.

At the Public Health Congress, which was held in Brighton some few months ago, many matters of great public interest were fully discussed. Among such matters was that of disinfection of ships for plague, concerning which Dr. Herbert Williams, Medical Officer of Health for the Port of London, read a paper, published in the *Journal of Royal Sanitary Institute*, January, 1911.

In order to disinfect a ship on which plague has been present a lethal gas is pumped into the vessel, and such gas may be either carbon monoxide, carbon dioxide, sulphur dioxide, or a mixture of these. Williams pointed out that in Hamburg carbon monoxide and carbon dioxide are employed, also a mixture of carbon monoxide and sulphur dioxide. In Sydney, Australia, an ingenious apparatus has been brought out. This machine acts by utilizing the gas from the furnace of the ship, which is conducted by a pipe from the funnels into a chamber, where it is scrubbed and washed, so as to cool it and to remove sooty particles. The gas, which consists mainly of carbon monoxide and dioxide, is then pumped by means of a blower into the various parts of the ship. However, after all, as Williams says, the question as to which is the most desirable method of destroying rats, resolves itself into that which is most simple, convenient and inexpensive. The fleas must be destroyed as well as the rats, and carbon monoxide and carbon dioxide cannot be relied upon to destroy these insects. Further, the gas is odorless and may be harmful to human beings, while sulphur has a pungent smell and, according to Williams, has some strong disinfecting qualities.

Dr. Howe agreed that sulphur dioxide was the only available practical material for the disinfection of ships in which cholera, yellow fever, and plague had occurred, but he dissented from the view that it was effective so far as plague was concerned. The germ of plague was carried by fleas, which could not themselves, travel far, but were carried about to considerable distances by rats. The rats, therefore, must be killed, and this object was best accomplished by carbon monoxide. True, the method was dangerous to man, but in recent years good regulations had lessened the risk, while its very secrecy, which made it deadly to man, made it deadly also to rats, which were killed instead of being frightened away. Howe drew attention to the obvious fact that sulphur, on account of its searching odor and thick fumes, frightened at once, and rats were apt to escape into out-of-the-way corners of the hold, so that most unfortunately they were not all destroyed by the fumigation.

The paper and discussion at Brighton were interesting, although the findings were indefinite. How effectively to kill rats and fleas on ships in which plague has existed—and this is what is meant by disinfection of such ships—is as yet an unsolved problem. There appears to be much force in Howe's argument that with a crafty, wary animal as is the rat, a disinfecant of the nature of sulphur is of comparatively little use. Despite its dangerous qualities, provided that the risk to human life can be minimized, carbon monoxide, or a mixture of this gas with carbon dioxide, will not scare the rat and will most assuredly destroy him. The crux of the problem is to prevent plague from being carried from country to country, the only effective means of prevention is to destroy rats on ships, and the knowledge sanitarians are in search of is as to which is the most effective method to destroy rats and their fleas.

WASSERMANN AND PIRQUET REACTIONS IN SCROFULOUS CHILDREN.

As is well understood at the present day scrofula, although to some extent a clinical entity, is far from having a single cause. Tuberculous scrofula makes up the great majority of cases, but, as Cornet and others have shown, some of the very worst cases clinically are not tuberculous at all. Cornet termed this form "pyogenic" scrofula, believing it to be due to the common exciters of suppuration. Among this class were to be found enlarged cervical nodes of a quasimalignant character. Despite the rapidity of their growth and the great size attained, no central softening or caseation ever occurs. The extreme condition is doubtless to be conceived as a localized lymphadenoma, or lymphoma, which may extend into the thorax, and also threaten death by compression of vital organs in the neck. A third form of scrofula is that which has been attributed from time immemorial to parental syphilis. It will be remembered that S. D. Gross always gave mercury to the scrofulous children of the soldiers of the Civil War. Similar instances could be cited. If syphilitic parents could beget scrofulous children whose scrofula yielded to mercurials, we should regard such scrofula as metasyphilitic, even though the known metasyphilitic diseases are not amenable to specific treatment.

It appears perfectly in line with what we know to test socalled scrofula for the new biological reactions. This is what Hertz and Thomsen of Copenhagen have recently done in a great number of children. Of 228 cases exhibiting *in toto* every variety of clinical scrofula, 192 reacted positively to Pirquet's test alone. Eight cases gave a positive Wassermann reaction. The patients who failed to react to either test are assumed by the authors to have had pyogenic scrofula. One child had a malignant lymphoma, while in another the case was of leukemic origin.

The eight positive Wassermann cases were of special interest. Some three of these also gave a positive Pirquet reaction and reacted weakly to the Wassermann test, recovering under nonspecific treatment. Four cases with pronounced Wassermann reaction recovered promptly under specific treatment. The eighth case in this series seems to have been doubtful in character; it gave both Pirquet and Wassermann weak or doubtful. To sum up, clinical scrofula is seen to be made up as follows: In a total of 228 cases 196 showed a tuberculous factor; 4 only were metasyphilitic; 26 were pyogenic, and of the two remaining cases one was a malignant cervical lymphoma, and one was leukemic in origin.

A Microorganism in the Blood of Acute Cases of Poliomyelitis.

A discovery that promises to be one of the most important that have rewarded the many recent investigations into the etiology of poliomyelitis is announced from the laboratory of the Department of Health of the State of Pennsylvania. S. G. Dixon, H. Fox, and J. B. Rucker report that in examining the blood from acute cases of poliomyelitis in human beings, and also in monkeys in which the disease was produced experimentally, an organism was found, different in morphological characteristics from any heretofore described which may or may not, on further investigation, prove to be the etiological factor in the causation of the disease. Blood smears being fixed in methyl alcohol for one minute and stained with carbolthionin, the organism appears as a faintly stained blue rod with regular cell wall about 10 microns long and about 0.8 micron in width, curved at an angle of 60° to 75° at one end, occasionally at both ends. At times, the curved end is bulbous. Some of the organisms appear to have a very finely granular protoplasm when the highest amplification is employed. They may be discerned by means of a 4 mm. dry objective but their characteristics are much more satisfactorily delineated under the 1-12 oil immersion lens. They are found free in the serum as well as within the body of the red blood cell. The bloods examined were from ten different cases of acute poliomyelitis in children and were taken during the epidemic of last summer and autumn, and from thirteen cases of the disease during the acute stage, which had been produced experimentally in as many monkeys. Blood smears from three normal human beings were carefully examined and, although the search for these organisms was diligently made, none were found. Smears were made from the bloods of thirteen normal monkeys with negative results. After inoculation with the virus these same monkeys gave positive results. The blood of other normal monkeys gave negative results. Smears from the cords and brains of paralyzed monkeys and of one human case did not reveal any of the new organisms, nor were these found in the filtered virus, but defibrinated blood three weeks to two months old from two paralyzed monkeys showed the forms in increased numbers. Cultures made from the blood of a paralyzed monkey, in blood bouillon, plain bouillon, and blood agar, examined after having been inoculated three weeks, showed the presence of the organism in increased numbers. Moving organisms in fresh blood have not been detected, nor have the organisms yet been isolated.

Reinfection with Syphilis After a 606 Cure.

Syphilographers have doubtless been awaiting a crucial test for the Ehrlich cure of syphilis, to wit, a reinfection. It has not yet been claimed that any immunity results from such a cure, although technically the sudden liberation of the endotoxins of the disease as a result of the injection might produce protective antibodies. Last December, at a meeting of the Paris Medical Society (*Berliner klinische Wochenschrift*, No. 7, p. 322), Milian reported a case of extensive primary syphilis (seven chancres) which was rapidly cured by one injection of 606. Spirochetes were present in abundance, the Wassermann reaction was positive, the inguinal glands were swollen, but there was no mention in the report of secondary syphilis. The chancres vanished and the glands resolved, and the Wassermann became negative under the treatment. Soon afterward there was sexual exposure to a woman with vulval mucous patches, and the patient developed two new chancres, which upon confrontation corresponded in position to the lesions of the woman. So-called chancre redux and chancroid could be excluded. This subject of reinfection is a vexatious one. Can a man be pronounced syphilitic before a roseola appears? So-called abortive cures through excision of a chancre show the difficulty of answering this question. Some authorities further insist that reinfection is so common that it may even occur within less than a year after primary infection.

Alcoholism and Phthisis.

Dr. Thomas D. Lister writes in the *Medical Press and Circular* on certain conditions which bear on the prognosis of phthisis. He is of the opinion, which is fortified by an experience of many years, that among the most common conditions found associated with consumption is that of alcoholism. At one time, and not so long ago, it used to be the custom to give alcohol in somewhat large quantities to phthisical patients. The administration of alcohol combined with overfeeding used to be the routine practice in Nordrach Sanatorium; this, however, is now discontinued. In the opinion of Lister alcoholism is very closely allied to the causation of tuberculosis, and in the prognosis of the disease he thinks it may be accepted as an axiom that the chronic alcoholic does not materially benefit by any amount of treatment. For instance, studies of mortality statistics show that the list of occupations suffering most from alcoholism almost coincides with the list of occupations in which phthisis figures most significantly. Thus in the liquor trade the incidence of pulmonary tuberculosis is most conspicuous. In short, the abuse of alcohol conduces to the diminution of the resistance of the individual to the tubercle bacillus. Of course, the life led by the bartender is inimical in most respects to health, the confinement, the oftentimes foul air, the spitting, and the dirty habits of many of the people with whom he is thrown into contact are all factors to be taken into consideration and all tend to produce a lowered vitality. But in any occupation in which the abuse of alcohol is practised there is invariably a high mortality from tuberculosis, and the statement that there is a very distinct relationship between alcoholism and pulmonary tuberculosis, Lister claims, is fully shown by mortality statistics.

News of the Week.

The Plans for Enlarging the New York Academy of Medicine.—Since the purchase by the New York Academy of Medicine of the adjoining lots at 15 West Forty-third street and 10 West Forty-fourth street, the work of planning for the best use of the new property and of raising money for such use has been assigned to two committees, one on Plan and Scope with Dr. Haven Emerson as chairman, and the other on Finance with Dr. L. Emmett Holt as chairman. The work of the Committee on Plan and Scope has fallen under two main heads: (*a*) General plan for the construction or reconstruction upon our entire property; (*b*) details of the needs of the various activities of the Academy and estimates of the space needed.

Because of the insufficient foundations of the present building, and because of the uncertain but large expense that would result from any remodeling of the present building, as well as the waste of expensive space if additional walls were erected, the committee found itself in accord with the architects who advised strongly against attempting to use the present structure as part of a completed new building. The committee unanimously recommended that it is to the interest of the Academy, on the ground of efficiency and economy, to plan so to use the entire area in the possession of the Academy that there will ultimately be a building new from the foundations up. This, it is believed, can be done without interfering with the activities of the Academy. Without having the supporting opinion of architects the committee has offered the following as the order and general scheme of construction which they consider advisable.

To build upon the lot at 10 West Forty-fourth street a structure of eight or ten stories to hold the power, heating, lighting, and ventilating plant, the offices of administration and stack. In this building several of the lower stack stories could be used for reading room and meeting room purposes temporarily during the period of destruction and rebuilding upon the property on Forty-third street. Two years should see such a stack wing completed, and by that time it is to be hoped that ways and means will be apparent for forwarding the building on the entire Forty-third street frontage. It is the opinion of the committee that no work should be undertaken until an acceptable plan is fully matured for the entire new structure. The details of the needs of the various activities of the Academy and the space required to house them would occupy too much space to give in full in this statement.

Certain conclusions were reached after detailed studies by three sub-committees. The stack should be built to hold 300,000 volumes, so placed as to allow of indefinite expansion by superimposing extra stories. The reading rooms for general and private use should give an increase of 50 to 100 per cent. beyond the present space. The main hall should seat 1,000, without the use of galleries. The provision for meetings and offices for medical and kindred societies should be so increased as to allow of a substantial addition to the annual revenue. The total area in cubic feet which will be needed to accommodate the various activities of the Academy amounts to 631,250 cubic feet, and it seems quite likely that 1,000,000 cubic feet will be the final estimate. The Academy can build on approximately 10,000 of its 12,000 square feet. This means that there is need of a building eight or ten stories high covering eighty per cent. of the entire property.

The Finance Committee appointed to secure funds for the new building has reported that through its efforts thus far over $84,000 has been pledged by 169 persons: 57 Fellows have subscribed $1,000 each; 36, $500 each, and 21, $250 each. Two physicians, not members, have subscribed $500 each. The committee when organized decided to proceed first to secure as many of the $500 and $1,000 subscriptions as possible and thus far its activities have been mainly confined to these classes. Sub-committees have been organized through which it is hoped to reach in the course of the next few weeks every member of the Academy. It was decided by the committee not to make an appeal to the outside public until the membership of the Academy had been pretty thoroughly canvassed.

The trustees of the Academy have appointed York and Sawyer, architects, to prepare plans for the new building.

The Canal Zone.—During the month of December, 1910, there was a total of 44 deaths among employees in the Canal Zone, an annual average of 10.91 per thousand. Of these, 32 were due to disease and 12 to violence. For Decembers of previous years the death rate has been as follows:

1904	19.44
1905	43.73
1906	30.27
1907	18.11
1908	25.03
1909	13.84

The annual average death rate per thousand in Panama, Colon, and the Canal Zone, including both employees and civil population, was 25.16 for December, 1910, a slight increase over the rate for the same month of the previous year, though less than in 1908, as shown by the following table:

1904	44.75
1905	58.78
1906	39.21
1907	28.50
1908	26.15
1909	21.50

Among employees the principal causes of death were: Nephritis, 6; lobar pneumonia, 7; malarial fever, 2; hemoglobinuric fever, 1; tuberculosis of the lungs, 4; organic heart disease, 2. No cases of yellow fever, smallpox or plague originated on or were brought to the Isthmus during the month. The work of sanitation has been carried on in the city of Panama as usual. Practically all of the defective roof gutters have been remedied so far as holding water and breeding mosquitos are concerned. There have also been 169,900 feet of ditches cleaned during the month. In Colon the malarial sick rate has shown a decided improvement over 1909; very few cases of typhoid fever have occurred and the sanitary situation is generally satisfactory. The quarantine at both Colon and Panama is of necessity very rigid, as the danger of the importation of plague and yellow fever is always present. Epidemics of yellow fever are reported at Guayaquil and Caracas and there are also many cases of plague in these cities.

Overcrowding at Bellevue.—Although the normal capacity of Bellevue Hospital is less than 1,100 beds, there was during February an average of 1,200 patients in the institution. On March 1 the number was 1,296 and on the following day 1,330, the highest in years. Since then there has been a slight drop, but the number of patients is still in

excess of the proper accommodations. To provide for the excess, cots have been set up in the halls and corridors, and some patients, it is said, are lying on hospital stretchers.

Is Anything the Matter with the Doctors? is to be the topic for discussion at a meeting of the Liberal Club of New York on March 15. Lincoln Steffens, Norman Hapgood, Upton Sinclair, and Dr. William J. Robinson are among the speakers who will solve the question.

Typhoid in Erie.—The epidemic of typhoid fever in Erie, Pa., still continues, and on March 2 it was estimated that there were 1,000 cases in the town and surrounding region. Up to that date 807 cases had been reported in Erie alone. Although the source of the infection has not been determined, it is suspected that the lake water has become contaminated with sewage. Improvements in the methods of handling sewage from the towns along the lake will possibly result.

Diphtheria in Baltimore.—Sixteen city blocks under strict quarantine, five hospitals closed to the public, and seventy-six cases of diphtheria up to February 28 have made the epidemic of the disease in Baltimore appear serious. The disease was first reported in the Johns Hopkins Hospital, where also the first death, that of a child patient, occurred.

Conditions in China.—Between the famine and the plague the Chinese are facing very serious conditions and it has been estimated that at least one million deaths will occur before relief from either is obtained. The official figures put the average daily deaths from the plague at 200, but it is doubtful if these figures are correct. The newspaper reports, at any rate, give far higher averages. For political reasons the Chinese authorities are directing their efforts to control the disease chiefly to the frontiers and along the railways. The Russians have asked to be permitted to cross the frontier and institute a quarantine in the infected Chinese towns along the Amur, but the Chinese are endeavoring to control the situation themselves. Lack of knowledge of modern methods of sanitation, however, makes the outlook very dark.

Sloane Hospital for Women.—The new gynecological pavilion of the Sloane Hospital for Women, New York, was formally opened for inspection on March 1 and for the reception of patients on the following day. The new building, which with the obstetrical wards of the hospital is controlled by the College of Physicians and Surgeons, Columbia University, is eight stories in height, has a frontage of forty feet on Amsterdam avenue, and is seventy-two feet deep. It has accommodations for twenty-eight private and twenty-six ward patients, and like the rest of the hospital is the gift of Mr. and Mrs. William D. Sloane, who have also provided the endowment. Dr. Edwin B. Cragin, who is professor of obstetrics in the college, is attending obstetrician and gynecologist to the hospital.

Discussion of Medical Education.—An interesting discussion on the subject of medical education was held on March 1, the occasion being the reception tendered by Mr. C. H. Mackay to the trustees of Columbia University and of the Presbyterian Hospital to celebrate the affiliation of the two institutions. The speakers were Prof. Theodore C. Janeway, Prof. Joseph A. Blake and Prof. William G. MacCallum, of the College of Physicians and Surgeons; Prof. Graham Lusk of the Cornell University Medical College, and Dr. Max G. Schlapp, Chairman of the Section on Mental Diseases of the Academy of Medicine. President Butler of Columbia University presided at the meeting.

Protest Against a New Hospital.—At a meeting of the New York State Board of Charities on February 28 to consider the incorporation of the proposed new hospital in the Bronx, a number of physicians of that borough protested against what they termed an invasion of the borough by Manhattan physicians. Of the eighteen physicians and surgeons interested in the plans for the new hospital, fifteen are residents of Manhattan. Dr. J. W. Brannan, Dr. Abraham Jacobi, and several other physicians spoke in favor of the hospital, while the opposition was headed by Dr. G. H. Starke of the Bronx Medical Association, who attacked the motives of the Manhattan doctors. It has been proposed to establish the new hospital in the heart of a much congested district which is not convenient to either the Fordham or Lebanon Hospitals. The opposing physicians have been planing, it is said, to erect a hospital on the site of the old Fordham Hospital.

Medical Conferences.—The Educational Alliance of New York announces a series of medical conferences given with the endorsement of the New York County Medical Society and the Academy of Medicine in the auditorium of the Alliance at 197 East Broadway at 8:30 P. M. The lectures are for physicians only, admission being had upon presentation of card. The following program has been arranged: Thursday, March 2, "Medical and Legal Aspects of Abortion," by Dr. John O. Polak; Thursday, March 9, "Sanitary and Moral Prophylaxis," by Dr. James Pedersen; Thursday, March 16, "The Physician's Duty in Obstetric Cases," by Dr. G. L. Brodhead; Thursday, March 30, "Gynecological Operations by the General Practitioner," by Dr. H. C. Coe; Sunday, April 9, "Lodge and Contract Practice," by Dr. A. A. Berg; Monday, April 17, "Medical Ethics and Their Application of Practice," by Dr. W. M. Polk; Sunday, April 23, "The Secret Division of Fees," by Dr. J. Brettauer; Thursday, April 27, "Abuses of Hospital and Dispensary Practice," by Dr. S. S. Goldwater.

Dr. E. K. Browd has been appointed visiting obstetrician to the People's Hospital, New York.

Centenarians Die.—Mrs. Belle Goldberg of New York died suddenly on March 1 at the age of 107 years. She was mentally bright and active up to the time of her death and attributed her long and healthy life to her principle of "Don't Worry."

Mrs. Jane Beam, said to be the oldest woman in Paterson, N. J., died on March 3, aged 103 years.

War on Spitters.—One hundred and fifty thousand women of the State of New York will be reached by the New York State Federation of Women's Clubs and asked to assist in the work of enforcing the ordinances against spitting, particularly in the street cars, in their home towns.

Cholera Sufferers.—The American National Red Cross has contributed $1,000 for the relief of the Jewish cholera victims in Tripoli. The money has been sent by the Department of State to the American Consul at Tripoli, who had reported that the situation there, especially among the Jewish residents, was desperate. The failure of the crops has added to the suffering.

Bellevue Alumni.—The society of the Alumni of Bellevue Hospital held its twenty-fifth annual meeting on February 28, when 250 members dined together at Delmonico's. Addresses were made by Chief Justice Isaac F. Russell of the Court of

Special Sessions, Dr. Stephen Smith, who was a member of the Bellevue staff in 1850; Dr. Charles F. Stokes, Surgeon-General of the Navy; Dr. William M. Polk, Dr. Joseph D. Bryant, and Dr. John W. Brannan. Dr. Floyd M. Crandall, president of the society, acted as toastmaster. Dr. Starling Loving of Columbus, O., the oldest living alumnus of the hospital, who joined the staff in 1849, also attended the meeting.

Guarding Water Supplies.—The House of Representatives on February 27 passed a bill enlarging the powers of the Public Health and Marine Hospital Service and changing the name to Public Health Service. Among other things the bill authorizes the investigation of water supplies and sewage disposal and the compilation of data on these subjects.

St. Mark's Hospital.—At the reorganization of St. Mark's Hospital, on March 7, the following new Board of Directors were elected: Dr. Benjamin T. Tilton (president), Dr. Alexander Shulman (vice-president), Dr. Andrew von Grimm (secretary), Drs. Otto Maier, C. A. von Ramdohr, and Charles Putnam, Messrs. John C. West, Thomas W. Slocum, and Julius F. Woikum. The following were added to the Medical Board: Drs. Tilton and Putnam, visiting surgeons; Dr. Andrew von Grimm, visiting gynecologist; Dr. Otto Maier, visiting pedriatist and obstetrician; Dr. Harry G. Watson, attending physician and visiting gastroenterologist to the St. Mark's hospital dispensary. Dr. Carl Beck has resigned as visiting surgeon.

Gifts to Hospitals.—Mrs. Whitelaw Reid has made an additional gift of $60,000 to the Red Cross Guild Hospital of San Mateo, Cal., which she established in memory of her parents, Mr. and Mrs. D. O. Mills. The money will be used in constructing additions to the hospital buildings.

The Lancaster General Hospital, Lancaster, Pa., has received a gift of $10,000 from Mrs. Minnie Bachman of Sharon, to be used for the endowment of a free room in memory of her husband, the late Morris Bachman.

Charitable Bequests.—The Nassau Hospital at Mineola, N. Y., receives a bequest of $100,000 under the will of the late Mrs. Alice A. Hicks of Old Westbury, Long Island, who died recently.

The following bequests are contained in the will of the late Catherine Herron of Philadelphia: St. Francis Hospital of Trenton, N. J., the Free Hospital for Consumptives, and St. Vincent's Maternity Home, $1,000 each; St. Joseph's Hospital and St. Agnes' Hospital, $500 each.

By the will of the late Anton W. von Utassy of Philadelphia a bequest of $5,000, payable on the death of the testator's wife, is made to the Hahnemann Hospital for the establishment of a free bed in the children's ward in memory of a daughter.

The Jewish Hospital of Philadelphia receives a bequest of $500 under the will of the late Abraham Weitzenkorn of Pottstown, Pa.

By the will of the late Louis Bosse of Philadelphia the following bequests are made: Medico-Chirurgical Hospital, $500; Philadelphia Home for Incurables, $200; Jewish Hospital, $200, and St. Christopher's Hospital, $300.

Tri-State Medical Association.—At the annual meeting, held in Raleigh, N. C., the following officers were elected for the ensuing year: *President*, Dr. J. Howell Way of Waynesville, N. C.; *Vice-presidents*, Dr. Thomas A. Anderson of Statesville, N. C., Dr. W. E. Anderson of Farmville, Va., and Dr. F. H. McLeod of Florence, S. C.; *Secretary-Treasurer*, Dr. R. E. Hughes of Laurens, S. C. The next meeting will be held in Columbia, S. C., on the third Wednesday in February, 1912.

Minnesota State Medical Examiners.—The Governor of Minnesota has appointed the following members of the State Board of Medical Examiners: Dr. F. R. Weiser of Windom, *vice* Dr. Thomas Lane; Dr. Annah Hurd of Minneapolis, *vice* Dr. Margaret Koch, and Dr. R. D. Matchin of Minneapolis, *vice* Dr. F. A. Knight.

Hospital Dissension.—Because of what the hospital trustees considered open insubordination, seven physicians and two internes, all women, on the staff of the Mary Thompson Hospital for Women, Chicago, were dismissed recently.

Boulder County (Col.) Medical Society.—The following officers were elected at the annual meeting on January 5: *President*, Dr. G. H. Cattermole; *Vice-President*, Dr. Clay Griffin; *Secretary-Treasurer*, Dr. Darbon Gillett.

Sangamon County (Ill.) Medical Society.—The following officers were elected at the annual meeting on January 9: *President*, Dr. George F. Stericker; *Vice-President*, Dr. W. A. Young; *Secretary-Treasurer*, Dr. O. H. Delchman.

Clark County (Ohio) Medical Society.—At the annual meeting on January 9, at Springfield, the following officers were elected: *President*, Dr. H. L. Heistand; *Vice-President*, Dr. C. W. Evans; *Secretary*, Dr. Arthur Dietrick; *Treasurer*, Dr. W. C. Taylor.

Spokane County (Wash.) Medical Society.—at the annual meeting on January 5 the following officers were elected for the ensuing year: *President*, Dr. E. D. Olmstead; *Vice-President*, Dr. W. W. Mackenzie, and Dr. H. P. Marshall; *Secretary*, Dr. Frank Hinman; *Treasurer*, Dr. C. M. Doland; *Corresponding Secretary*, Dr. X. L. Anthony.

Butte County (Cal.) Medical Society.—The annual meeting was held at Chico on January 10, officers for the ensuing year being elected as follows: *President*, Dr. D. H. Moulton; *Vice-President*, Dr. C. L. Browning; *Secretary-Treasurer*, Dr. Ella Gatchell.

Kankakee County (Ill.) Medical Society.—Officers for the year 1911 have been elected as follows: *President*, Dr. H. Wheeler of Grant Park; *Vice-President*, Dr. J. H. Gernon of Kankakee; *Secretary-Treasurer*, Dr. H. S. Spencer of Kankakee.

Mannington (W. Va.) Medical Society.—The following officers have been elected to serve for the ensuing year: *President*, Dr. W. J. Leahy; *Vice-President*, Dr. M. F. Hamilton; *Secretary*, Dr. W. R. Andrews; *Treasurer*, Dr. Phoebe Moore.

Central Oklahoma Medical Association.—At the annual meeting in Enid on January 12 officers were elected as follows: *President*, Dr. F. H. Clark of El Reno; *Vice-Presidents*, Dr. E. B. Ebright of Enid, and Dr. C. E. Thompson of Kremlin; *Secretary-Treasurer*, Dr. M. M. Roland, Oklahoma City.

Southern Surgical and Gynecological Association.—At the meeting of the association held in Nashville, Tennessee, on December 14 and 15, the following officers were elected: *President*, Dr. Rudolph Matas, New Orleans; *Vice-Presidents*, Dr. Guy L. Hunner, Baltimore, and Dr. J. Garland Sherrill, Louisville; *Secretary*, Dr. W. D. Haggard, Nashville; *Treasurer*, Dr. W. S. Goldsmith, Atlanta. The next meeting will be held in Washington, D. C.

South Georgia Medical Association.—The an-

nual meeting was held in Cordele on December 7. Officers for the ensuing year were elected as follows: *President*, Dr. A. B. Heyward, Warwick; *Vice-President*, Dr. J. S. McKenzie, Cordele; *Secretary-Treasurer*, Dr. T. E. Bradley, Cordele.

North Texas Medical Society.—At the meeting held at Dallas on December 14, the following officers were elected: *President*, Dr. C. R. Gray Bonham; *Vice-Presidents*, Dr. H. G. Harris, Plano, and Dr. H. K. Beall, Fort Worth; *Secretary-Treasurer*, Dr. Leslie Moore, Dallas. The next meeting will be held at McKinley in June, 1911.

South Texas Medical Association.—The annual meeting was held at Port Arthur on December 8, when the following officers were elected: *President*, Dr. W. F. Thompson, Beaumont; *Vice-President*, Dr. H. R. Dudgeon, Galveston; *Secretary-Treasurer*, Dr. E. F. Cooke, Houston. The next meeting will be held in Galveston on the second Thursday in June, 1911.

Obituary Notes.—Dr. William Worrall Mayo, father of Drs. William and Charles Mayo of Rochester, Minn., died at his home in that city on Monday of this week. His strength had been failing for a year and his death is ascribed to the infirmities of old age. He would have been ninety-two years of age on May 31. Dr. Mayo was born in England, but came to this country in early life. He was graduated in medicine from the Medical Department of the University of Wisconsin in 1854. After graduation he moved to Leseur, Minn., where he practised his profession until he went to Rochester in 1863, having been appointed provost surgeon. He retired from practice several years ago. In 1873 he was elected president of the Minnesota State Society, of which he was one of the founders. He organized the Olmstead County Medical Society twenty-nine years ago and had been a member of the American Medical Association for fifty years. He served the city of Rochester several times as Mayor.

Dr. Homer Baxter Sprague of New York, a graduate of the Bellevue Hospital Medical College in 1881, a member of the New York State and County Medical Societies, the Physicians' Mutual Aid Association, and the Lenox Medical and Surgical Society, died at his home of pneumonia on February 25, aged 51 years.

Dr. Daniel A. Currie of Englewood, N. J., a graduate of the University of Buffalo Medical Department in 1864, a member of the New York Academy of Medicine and of the United States Association of Military Surgeons, and the first Mayor of Englewood, died at his home suddenly on February 28, aged 70 years.

Dr. Walter Remsen Brinckerhoff, assistant professor of pathology in the Harvard Medical School, Boston, died at his home of pneumonia after a short illness on March 2, aged 36 years. Dr. Brinckerhoff was graduated from Harvard University in 1897 and from the Medical School in 1901. He served as assistant pathologist at the Boston City Hospital from 1901 to 1903, and as assistant at the Medical School from 1903 to 1906, and was made a fellow of the Rockefeller Institute in 1904. In 1906 he became Director of the Leprosy Investigation Station, Hawaii, of the United States Public Health and Marine Hospital Service, remaining there until 1910, when he returned to the Harvard Medical School as assistant professor of pathology. He had also served as physician to the Carnegie archeological expedition to Trans-Caspia in 1905, and was a fellow of the American Association for the Advancement of Science and a member of the American Association of Pathologists and Bacteriologists, and of the Boston Society of Natural History.

Dr. M. James Galloway of Philadelphia, Pa., a graduate of the Philadelphia College of Medicine and Surgery in 1873, died at his home on February 28, aged 73 years.

Dr. Caleb Horace Closson of Altoona, Pa., a graduate of the Jefferson Medical College in 1872, and the first secretary of the Altoona Board of Health, died at his home on February 25, aged 62 years.

Dr. James M. Patterson of Verona, Tenn., a graduate of the University of Nashville, Medical Department, in 1859, a member of the Tennessee State and Marshall County Medical Societies, died at his home on February 18, aged 82 years.

Dr. Thomas R. Mask of Wilmington, N. C., a graduate of the Leonard Medical School, the medical department of Shaw University, Raleigh, died at his home on February 19, aged 48 years.

Dr. Philip A. Austin of Muscatine, Ia., a graduate of the Homeopathic Hospital College, Cleveland, O., in 1856, died at his home of pneumonia on February 15, aged 77 years.

Dr. Lee W. Fulton of Alexander, Ill., a graduate of Rush Medical College, Chicago, in 1869, died at his home after a long illness on February 18, aged 73 years.

Dr. Emmett Densmore of Brooklyn, N. Y., a graduate of the New York University Medical College in 1885, died at Cassadaga, Fla., on February 19, aged 73 years.

Dr. Uranus O. B. Wingate of Milwaukee, Wis., a graduate of the Dartmouth Medical School, Hanover, N. H., in 1874, a member of the American Medical Association, the American Medico-Psychological Association, the Wisconsin and Massachusetts State Medical Societies, the American Public Health Association, the New York Medicolegal Society, and the Milwaukee County Medical Society, professor of nervous and mental diseases in the Wisconsin College of Physicians and Surgeons, neurologist to St. Mary's Hospital, visiting neurologist to the County Hospital, consulting physician for nervous diseases to St. Joseph's Hospital, and ex-Commissioner of Health in Milwaukee, died of pneumonia at his home on February 18, aged 62 years.

Dr. Benjamin W. Searle of Ottumwa, Ia., a graduate of the College of Physicians and Surgeons, Keokuk, Ia., in 1873, died at the Wesley Hospital after a long illness on February 17, aged 60 years.

Dr. Edwin G. Knill of Detroit, Mich., a graduate of the Royal College of Physicians and Surgeons, London, England, in 1873, and of the Toronto University Medical Faculty in 1883, attending physician to the Harper Hospital, Detroit, and adjunct professor of pathology in the Detroit College of Medicine, and a member of the Michigan State and Wayne County Medical Societies, died suddenly at his home on February 10, aged 55 years.

Dr. Oscar F. Pile of Memphis, Mo., a graduate of the College of Physicians and Surgeons of the University of Illinois, Chicago, in 1888, a member of the American Medical Association and of the Missouri State and Scotland County Medical Societies, died at his home on February 12, aged 52 years.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

HUNTERIAN CELEBRATIONS AT THE ROYAL COLLEGE OF SURGEONS—THE ORATION—THE LECTURES ON COLOR BLINDNESS—ARRIS AND GALE LECTURES ON MUMMIFICATION—ITEMS—OBITUARY.

LONDON, February 17, 1911.

HUNTER'S day has come again and has been, of course, the event of the week at the Royal College of Surgeons. The oration was this year delivered by Mr. Edmund Owen, consulting surgeon to St. Mary's Hospital, who observed that we are now only two years short of a century since John Hunter's executors provided for the delivery of an annual oration on his birthday (February 14). John was the youngest of ten children, most of whom died young, and his mother spoilt him. It would have been better for him, said Mr. Owen, if his mother had helped him to keep a better command over himself, for he was apt to be overbearing in his manner and, if his wishes were thwarted, intolerant. Up to the time he came to London he had seemed to be an idler, but here he was at once set to work at dissections for the lectures of his brother (Dr. William). This work he did so well that he at once gained his brother's approval and confidence and though he lived a free and easy life outside, he stuck closely to his hospital work. In time he became by far the greatest surgeon of his time, but seemed only to practise for the sake of attaining the means of adding to his museum. Close friendship existed between him and one of his pupils, Jenner, but the great discovery of Jenner was not revealed until after Hunter's death. Outside his profession Hunter displayed little interest, which Mr. Owen regretted, for, said he, every medical man should have interests outside; intemperance in work was well-nigh as harmful as in eating or drinking. Six years after his death Hunter's museum was purchased by Parliament for the nation and offered for keeping to the Royal College of Physicians. On their declining the responsibility it was entrusted to the Royal College of Surgeons. As a man and as the "founder of a museum which is without a rival in the world," many have dwelt on the greatness of his intellect. The details of his life are well known, his history is an open book, no part of his industrious life is hidden; we know the full story of his death and have a sufficient account of the result of the examination of his body to enable us to understand its cause. To this point the orator proceeded to direct the attention of the assembly. A man is as old as his arteries, and though Hunter died under 65 he had for years been the subject of arterial disease. The orator attributed this to the disastrous experiment upon himself a quarter of a century before. Many others have been ready to offer themselves on the altar of science in the hope of advancing pathology or the prevention or treatment of disease. But Hunter had abundant opportunity of observing the progress of syphilis in patients who came to him. Yet he was so desirous of watching every effect produced by the virus, that he calmly dipped a lancet in venereal matter and inoculated himself. He was then in his fortieth year and knew the seriousness of the constitutional disease with which he was infecting himself. As he watched he found he could check it by a certain line of treatment. But he stopped when he began to get better, writing that it was not the intention "to cure completely at present." His throat became ulcerated and when the treatment caused the ulcer to "skin over" he stopped again, as he did not then wish to destroy the poison, but to see what part it would next attack. Blotches on the skin and renewed sore throat followed. Later he set to work to cure himself, and when he discontinued the treatment about three years had passed from the date of inoculation. He seemed satisfied that the knowledge he had gained was a sufficient reward for what he had undergone, but no medical man can share that feeling. The price was too heavy. The orator had little doubt that the progressive arterial degeneration of which he was the subject was greatly, if not altogether, due to the self-inflicted disease from which he never actually recovered. It was that which rendered him feeble in body and restless and irritable in mind. To see this is to make us look on his vast achievements with increased respect and to regard his failings with unstinted sympathy. It is a sad story—the man of such giant mind as the world seldom produces, worn out with incessant work, want of rest, and torn to pieces by mental torture, the result of his work and his bodily condition.

The festival dinner was held in the library of the college in the evening. The president, Mr. Butlin, proposing the toast of the visitors, called attention to the fact that the museum was national property kept and paid for by the college. He doubted if there was a similar instance of a national museum being upheld by a private body, but in spite of that the college took the greatest pride in and lavished time and money on the most splendid museum of its kind in the world. The Lord Mayor, responding, said their college sprang from one of the old city guilds and they of the city were extremely proud of their offspring.

"Color blindness is not a good name," says Dr. Edridge-Green, who is our chief authority on the condition to which it is applied, and, indeed, as to all the facts concerning that condition. Nevertheless, the term has obtained so firm a position that it is not likely to be displaced by a more strictly accurate one. Of course, in the majority of cases there is no blindness to colors in the ordinary sense. When people confuse red and green, it is not because they see red as green or green as red, but because both excite a similar sensation of color. Professor Edridge-Green has just delivered two Hunterian lectures at the Royal College of Surgeons on "Color Vision and Color Blindness," in which he has laid down the theory and facts on the one hand and on the other the requirements of a test for the detection of the defect from a practical point of view. It is chiefly to the latter point I want to confine my summary, though I may preface it by saying that his opinion is that the ordinary form of color blindness is caused by a defective development of the portion of the brain whose function is the perception of color, but not excluding any portion of the retinocerebral apparatus, defect of which would have the same result.

It is of the greatest importance that all signalmen in the railway or marine services should be able to distinguish between the standard green, red, and white lights in all conditions in which they may be placed. A sailor or engine driver has to name a light to himself when he sees it—not to match it. He knows red is for danger, green for caution, and white for all right. A test, therefore, ought to be

such as he will not mistake and one which he cannot be coached through, yet the tests in common use fail in this last requirement. It is sometimes most desirable to show the candidate and his fellows that a rejected person is really dangerous. A man who is refused may be dissatisfied and his fellows may sympathize, but if they see him tested and calling a red light green they will feel satisfied that he is dangerous as a signalman. Dr. Edridge-Green has invented a lantern which provides a perfect test. It contains four discs, three carrying seven colored glasses and one with seven modifying glasses. There is a diaphragm for diminishing the size of the beam of light projected. This is graduated in respect to three apertures to represent a 5½-inch railway signal bull's-eye at 600, 800, and 1,000 yards when the test is made at 20 feet. The lantern was shown at the lecture and its capacities demonstrated. The professor said, too, that on obtaining a lantern the observer should very carefully test himself with it first of all. He may think he can improve it, but he had better confine himself to finding out how the different lights appear to him under different conditions of general illumination. The colors used in the lamp have never been altered, though we may be sure they would have been if Professor Edridge-Green, with his extensive experience and intense interest, had found it possible to improve his lamp. He assured his hearers he had never met with a single color-blind person who was not easily detected with it, though he had seen many who had passed other tests. Full directions for carrying out the test under various circumstances were given and the reasons in each case explained. Seeing the certainty of the Edridge-Green method and the ease with which it can satisfy the rejected and his colleagues and the danger of employing a defective signalman, the great lesson of these lectures seems to be that other methods should no longer be used. Many allow dangerous persons to pass, and such persons can be coached or can unconsciously or consciously teach themselves enough for ordinary purposes, but never can be safe. The most known tests are Holmgren's, Stilling's, and Nagel's. All these can be passed at the first attempt without coaching by certain dangerously color-blind persons. In one railway using Holmgrem's one in 300 were rejected; on substituting the lamp 12 in 300 were detected. That Holmgren's test rejects many normal-sighted persons is shown by the reports of the Board of Trade; about 50 per cent. of those who appeal are found to have normal sight and have been wrongly rejected.

The history of mummification is the subject of the Arris and Gale lectures, also at the College of Surgeons, and given by Professor Elliot Smith, who traced the invention of embalming to the earliest plan of the Egyptians burying their dead in shallow graves in the desert sands. The dryness of the air and heat of the sun often led to the desiccation and preservation of the body. The depredations of jackals, as well as the plundering of the graves in search of valuables buried with the dead, led to the discovery that the body was often preserved in an imperishable form, and the lecturer had no doubt that this knowledge colored the religious ideas of the prehistoric Egyptians and shaped their beliefs into the conviction that the preservation of the body was the condition necessary to attain immortality. This would lead to more care of the body and lavish expenditure on tombs—rendered easier toward the middle of the predynastic period by the discovery of copper and the scope that metal gave for the construction of tools, shown by the end of that period in the invention of coffins in wood and stone.

The new Dermatological Society has held its first dinner. One of the toasts was "Kindred Societies," and there were repudiations of any antagonisms, so we may hope for peace.

University College, having secured the site for extension, is appealing for an additional £50,000 to build and equip new laboratories.

Rachi-strychno-stovainization is the pretty name given to a method of anesthesia devised by M. Fzaicon, a Roumanian, and which is said to suspend sensation while the patient retains full consciousness. He is reported to have operated under its influence on himself with complete success.

Yesterday the Royal Society was presented with a portrait of Sir William Crookes.

The Fothergillian Gold Medal of the Medical Society of London has been awarded to Dr. F. W. Mott.

Dr. James Edmunds, consulting physician to the Temperance Hospital, and one of its founders, has died at Brighton, to which he retired some years ago, aged 79. He qualified at the two Royal Colleges in 1854, having the previous year gone from the London Hospital as a senior student to assist in the cholera epidemic at Newcastle and Dundee. He took M.D. at St. Andrews in 1862 and joined the College of Physicians in 1874. He was the medical officer of health and analyst for St. James's for twenty-seven years and medical officer of the police for some seven years. But his great work was in the temperance movement, of which he was a strenuous advocate in every department. Naturally the medical side had his first attention and as a pupil of W. B. Carpenter, at the London Hospital, his physiological ground was well laid. But the social side of temperance appealed equally to him and he labored zealously at promoting it, so that he became identified with it in all its ramifications.

Dr. John Stamford Walton died on the 4th inst., aged 75. He had been Coroner in Yorkshire for nearly forty years and was also surgeon to the Cottage Hospital at Northallerton.

Dr. Joseph Dawson Crawford of Liverpool died on the 7th inst. He qualified in 1855 and took the F.R.C.S.E. in 1859, was for many years surgeon to the Hospital for Cancer and Skin Diseases in Liverpool, where he passed his long professional life, and was highly esteemed. He had for some time retired.

Dr. Ch. Hy. Bennett, J.P., ex-vice-president of the Gynæcological Society, and honorary surgeon-major of the City of London Volunteers, died yesterday, the 16th inst. He graduated at St. Andrews, 1860, and took the double London qualification the same year. He was associate of the Order of St. John of Jerusalem.

OUR LETTER FROM PARIS.

(From Our Regular Correspondent.)

SEPERATION OF THE URINE OF THE TWO KIDNEYS IN THE BLADDER—ELECTION AT THE ACADEMY OF MEDICINE—DEPOPULATION—NECOLOGY.

PARIS, February 10, 1911.

At the Surgical Society occurred an interesting discussion on endovesical separation of the urine of the two kidneys with the Luys separator, occupying the attention of the society for several sittings. In

a woman attacked by right sided calculous pyonephrosis, Guinard, after having practised endovesical separation of the urines of the two kidneys, obtained the following result: on the right the urine was purulent, on the left the liquid was clear. The analysis of the two urines showed that on the left side the clear liquid contained no trace of urea, and consequently was not urine; from this Guinard concluded that on the right he had a pyonephrosis, on the left a normal kidney. He performed right nephrectomy and the patient died of anuria some days afterward; at the autopsy it was shown that there was a congenital absence of the left kidney. Guinard blamed the separator for having given him bad results. Savariaud and Hartmann took up the discussion to express their surprise at this unexpected conclusion. The separator had functionated perfectly, showing a purulent urine on the right in relation with a calculous pyonephrosis, while on the left it had shown exactly what existed, that there was no kidney, since the few drops of liquid collected by the separator contained no trace of urea. The error came not from the instrument, which had acted perfectly, but from the false interpretation giving a bad result. As a sequel to this observation Marion, confounding the results obtained by different separators, spoke against the method of endovesical separation of urines without giving any decisive proof of his assertion or citing any personal experience.

Tuffier, having cited from memory an observation in which the separator had given bad results, found himself under the necessity of rectifying his error at another sitting, for the observation cited had been previously published. But two very interesting papers were presented on endovesical separation of the two kidneys, one by Hartmann and the other by Delbet. Hartmann, in the presence of the criticism to which separation had been subjected, showed that he had had extended experience of this method, since in the 300 operations that he had done on the kidney he had never established the indications for operation except by the results given by the application of the separator of Luys. It had never indicated an error, and he thinks that this simple method of examination at the door of every surgeon who is not a specialist deserves to be preserved and to still render service. Hartmann remains faithful to simple endovesical separation of the urine, which has always proved satisfactory to him. From the point of view of the observation of Guinard, Hartmann showed that the separator had very exactly divided the bladder; it separated well the urines of the two kidneys when it was well applied, and separated them badly when badly applied. It is with separation as with all methods of examination: they only give exact results when correctly applied. Pierre Delbet, after having made a certain number of endovesical separations of the urine with the Luys separator, has never seen this method at fault. Often the separator has rectified the clinical diagnosis at the bedside of the patient. In all observations tending to throw doubt upon the certainty of the endovesical separation of urine there is not one which gives a serious argument against separation. Endovesical separation of the urine and catheterism of the ureter are not opposing, but allied methods. Separation furnishes in many cases sufficiently precise results to avoid the necessity of catheterization of the ureters; it often gives information that cannot be neglected. Rouville, of Montpellier, communicated an interesting observation, showing that a well-performed separation made with the Luys separator constitutes a precise method of investigation. In this observation the perfection of the result obtained by the Luys separator was so complete that the test for blood in the urine was absolutely negative in the urine of the left kidney, while that of the right kidney was bloody. Lumbar nephrectomy of the right kidney was followed by the best results; the patient seen seven months after the operation was marvelously well.

The Academy of Medicine recently had its election for the year 1911. Lannelongue became president; Gariel was named vice-president; Madame Lucas-Championnière and Hallopeau are members of the council; Weis was elected secretary, and Hanriot, treasurer.

At the Society of the Internes of the Hospitals of Paris the question of depopulation was discussed by Jayle. The problem is whether by legislative measures we may prevent the lessening and destruction of the people. Up to this time the measures taken in France are of little importance, since the results may be considered as nil and the progressive diminution continues. The principal actual causes of depopulation in France are: (1) The continued protection of all subjects who have some physical stigma and the systematic indifference to the healthy subjects. (2) The social privileges enjoyed by the unproductive. (3) The mortality and morbidity among the children of the poor. To remedy these three principal causes we must proclaim the principle that the healthy child must have the advantage over the sick one. Again, we must establish the principle that every man in easy circumstances must have three children or pay for the support each year of three children. Only those should be exempt who have other family charges, adopted children, or a revenue from labor insufficient for such support. Finally we must give to poor families, especially to those who have more than three children, considerable sums of money; the amount of these sums should be greater according to the health of the children. The principal end to be reached is to protect the healthy portion of the population and to prevent the children of the poor from dying by making the unproductive rich pay for their support.

Henri Huchard, Honorary Physician of the Hospitals, member of the Academy of Medicine, is dead. He was one of the modern masters of cardiac pathology. More than any other he contributed to precision in the pathology of hypertension, arteriosclerosis, and arterial cardiopathies. It was he who introduced into general practice the lactovegetarian diet and the rational employment of digitalis and iodides, and these were exploits that serve to establish a universal reputation like his. Without the professor's title he was perhaps one of the greatest professors of his time, because he held his titles by his authority, his knowledge, and his talent for teaching. Huchard was a great worker. While an interne he received a jet of pus in one eye and the results were at first so grave that it was believed his sight would be lost, but although he came out his trouble physically diminished he was elevated and refined by his sufferings. Huchard was in the fulness of his activity when suddenly he perceived that solid food was arrested in his throat, and in July last he submitted to a painful operation which condemned him irrevocably to repose. Passionately fond of his art and of all the causes that he be-

lieved to be just, Huchard had the respect of all his adversaries, for all saluted in him a master of high endeavor.

OUR BERLIN LETTER.

(From Our Regular Correspondent.)

ROBERT KOCH MEMORIAL MEETING—KOCH'S LAST RESTING PLACE—PROPOSED LAW REGULATING PRACTICE OF MEDICINE.

BERLIN, February 2, 1911.

On December 18, 1910, there took place in the large auditorium of the university a celebration in memory of Robert Koch. Once more there was conjured up, in the touching eulogy of Koch's successor Gaffky, the portrait of the never-to-be-forgotten investigator, who has found his last resting place at the spot where he had carried on his work. His ashes are inurned in the western wing of the Institute for Infectious Diseases. This mode of interment is an unusual one in scientific circles. A dim antechamber with its black covered oaken walls prepares the visitor for the mournful memorial beyond, whose walls are covered with handsome cabinets containing mementos of Koch, and the golden book of the Robert Koch Foundation. The walls are of yellow Italian marble, divided off by columns of blue and gray, while the floors consist of white and variegated black and green marble. The light enters the room dimly through a trefoil window of blue glass and bronze frame. The sole furnishings are a marble bench beneath the window and two antique vases suspended from the ceiling. Upon one wall are engraved in dark letters the list of Koch's achievements, beginning with the discovery of the anthrax bacillus in 1876. In the center of the opposite wall there is an excellent relief portrait of Koch executed in white marble. Beneath this a marble tablet conceals the ashes which are buried in the wall. Thus an eloquent tribute has been erected for the eternal rest of the investigator who during life knew no rest. Particularly fitting is the contrast between the repose of this sepulchral chamber and the busy activity of its surroundings. The view of the golden book of the Robert Koch Foundation is alone worth the visit. This volume is one-half a meter long and has a cover decorated in gold, with a relief portrait of Koch in bronze. The first page contains a history of the Foundation, and then follows a long list of the contributors with their autographs. The first name is that of the Kaiser, who contributed 100,000 marks, and next comes that of Carnegie with 500,000 marks as his offering. The Foundation was established in 1907 on the occasion of the twenty-fifth anniversary of the discovery of the tubercle bacillus.

After many years of striving on the part of the profession, a bill has at last been introduced into the Reichstag for the control of abuses in the practice of medicine. Since 1869 the treatment of the sick has been open to all, and during this time the number of quacks has steadily grown. Abuses have become so prominent that the government has seen the need of interference. The proposed law does not entirely eliminate the freedom to practice. Only diseases affecting the public health and venereal diseases are to be restricted to the practice of approved physicians. All the rest are to be subject to a rigid control. The advertisement of secret remedies is to be controlled. The discussion over this bill was remarkable. Most of the speakers espoused the cause of the charlatans. The greatest objections were raised by the Social Democrats, who for many years have waged an open war against the doctors who have rightfully opposed the terrorism of the Social Democrats. The latter therefore sang the praises of the nature healers and enumerated the list of these physicians who in past years have been fined for errors in practice. They demanded the establishment of chairs for the teaching of nature-healing, asked the repeal of the compulsory vaccination laws, and demanded also a law for the compulsory treatment of all individuals requiring medical care gratuitously, the State assuming the burden. The legislators who were with the doctors retorted that the law was designed not so much in the interest of the physicians but for the protection of the public; that the law was not to be used against the nature-healers but against the quacks. Inasmuch as the conception of a quack is not easily defined, the question in the law hinges about approved and non-approved physicians. First Doctors Arning and Struve placed the issue in its correct light. The minority of the quacks was one disadvantage. One of the greatest dangers of quackery was the frustration of the fight against contagious diseases. The distinction between the medicines of the schools and nature-healing was an artificial one, for every physician employed natural methods in treatment, while the nature-healers used artificial remedies. The result of the discussion was a dismal one. It plainly showed that the majority of the legislators sided with the nature-healers, that they had not realized how the regularly qualified practitioners are injured by tolerance of quackery. The prospects of passage of the law are quite doubtful. A committee of twenty-eight members was appointed for its further consideration.

OUR VIENNA LETTER.

(From Our Regular Correspondent.)

A NEW REACTION FOR SERUM-SICKNESS—TREATMENT OF FRACTURES OF THE FOREARM—X-RAY SHADOW OF CALCAREOUS DEPOSITS IN THE HEART—ORIENTAL BOIL.

VIENNA, February 10, 1911.

F. Bauer has made a new discovery regarding serum-sickness. Hitherto a characteristic reaction of the latter, appearing regularly and parallel to the intensity of the affection, has not been determined. Berger has established that after the injection of serum hemagglutinins are produced, just as in the case of red blood cells. The hemagglutinins from horse's blood are normally present in human serum in slight amounts. These are materially increased by the injection of antidiphtheritic serum. This increase persists for three weeks, and in some cases for as long as three years. A positive reaction indicates the probability of the presence of serum-sickness. The technique of the reaction is practically the same as that of the Widal reaction, only, instead of typhoid bacilli, serum-free horse's blood is used. Since in rabbits after the injection of human mild and egg-albumin a corresponding hemagglutinin formation is detectable, Bauer would employ the reaction as a means of solving the problem, whether any of the manifestations of serum-sickness (urticaria, idiosyncrasies, etc.) are dependent on the albumin susceptibility. The exanthem appears in eight to twelve days; the reaction begins about the sixth day and reaches its maximum in from twelve to fourteen days.

Otto V. Fisch has devised an improved method

of treating fractures of the forearm. In the management of uncomplicated fracture of both bones, one frequently finds considerable displacement, which is reduced with difficulty. The various splints and extension apparatus are usually effective, but their application is not simple, and they do not guarantee a lasting apposition of the fragments. It is advisable in every recent case of fracture of the forearm to attempt manual setting of the fragments under general anesthesia and with the aid of the *x*-ray. Even with these measures Fisch was not able to accomplish his object in a case of fracture of two days' duration. The thought occurred to him that one might employ the same method that is used in reducing a dorsal dislocation of a finger, namely, by causing the distal fragment to override the proximal, and then causing the distal portion to be strongly flexed dorsally, and, with the thumb in the angle between the two fragments, by means of the thumb the distal fragment would be forced into place. Simultaneous traction in the arm would elicit the familiar crepitus and would indicate that the bones are properly in apposition. The irregularity of the apposed surfaces gives the fragments a considerable degree of stability, so that, without fear of further displacement, active rotatory movements may be carried out.

Gottwald Schwarz has succeeded in getting an *x*-ray picture of the heart during life. The patient was a male, 44 years old, in whom the heart shadow was of normal size and shape. But within this shadow there were a large number of irregular, dark shadow spots of the size of a bean, and at the upper portion of the left ventricle a cordlike, dark band, 3 cm. long and 2 cm. thick, which pulsated actively, hence lying beneath the surface of the heart. The phenomenon gave the impression as if a darning needle was embedded in the heart muscle. Close examination of the history revealed no evidence of the introduction into the body of such an object, and the conclusion was that the shadow was one of a calcareous deposit. In his younger days the patient was a prize fighter and one day received such a blow over the region of the heart as to be rendered unconscious, and to be ill for several weeks. He apparently had a traumatic pericarditis, such as is described by Kaufmann in his "Handbook of Pathological Anatomy." If, as seldom occurs, calcium salts are deposited in the pericardium, then the heart appears as if surrounded by a ring or armor; giving rise to the "stony" or "armored heart." Simmonds has demonstrated by *x*-ray pictures the existence of such a condition as he confirmed post mortem.

Hans Lorenz presented before the Practitioners' Society a case of Aleppo-boil. This condition is endemic in the Orient and in North Africa and is caused by a protozoan, the *Leishmania tropica*, which is introduced through a local infection. It is noted that frequently in Europeans who have traveled or visited in the Orient the boil breaks out months after their return to Europe. The mode of infection is unknown, but is supposed to be through the intermediation of an insect. One attack gives permanent immunity. The prognosis is favorable. The swelling softens and forms an abscess that slowly clears up and granulates. Spontaneous healing occurs in the majority of cases in from six to nine months, occasionally in much shorter time, but sometimes it is delayed for from two to three years.

A Review of the Midwife Situation. A. B. Emmons, 2d, and J. L. Huntington.
Some Practical Points in Connection with Dislocation of the Hip, and its Reduction by the Method of Bigelow. G. H. Monks.
Ovarian Pregnancy. Report of a Case. E. B. Young and L. J. Rhea.
A Note on the Symptomatology of Abscess of the Liver. W. C. Quinby.
The Disappearance of a Catheter in the Bladder and Its Subsequent Spontaneous Passage. W. E. Wilson.

The Midwife Situation.—A. B. Emmons, 2d, and J. L. Huntington refer to the unsatisfactory condition of obstetric practice wherever the midwife exists. Two standards of skill and a divided responsibility inevitably are found. The midwife must either be a competent, trained obstetrician, or she must become a subordinate, cooperating with the obstetrician, as does the excellent trained obstetrical nurse, relying on his judgment and resting with him the responsibility of the two lives, before a system harmonious and satisfactory can result. The history of temporizing with the ignorant, half-trained, often malicious midwife to-day reads like many another misguided "freedom" which is virtually a license by the State to practise quackery on an ignorant, unsuspecting public. The women and infants pay for this "freedom" in deaths, unnecessary invalidism, and bindness. The obstetricians are the final authority to set the standard and lead the way to safety. They alone can properly educate the medical profession, the legislators, and the public.

Dislocation of the Hip.—G. H. Monks concludes that for practical purposes all regular dislocations of the hip are, in reference to the acetabulum, either posterior or anterior; and that, whichever the dislocation, an imaginary arrow on the exposed surface of the lower leg pointed toward the flexed knee will, in case the Bigelow method of replacement is to be used, remind the surgeon during the flexion whether to make the knee describe an inward or an outward curve.

Ovarian Pregnancy.—E. B. Young and L. J. Rhea report a case which clinically appears one of true ovarian pregnancy, as an embryo was found in the blood clot contained in tissue corresponding to a part of the ovary, the ovary itself being surrounded by blood clot and connected to no other structure except in the normal manner. The ostium of the tube on the same side was closed; and the opposite tube showed no disturbance except such as may come from pelvic peritonitis. The blood clot was entirely about the left ovary and did not reach the tube on the right. The right ovary showed no corpus hemorrhagicum.

Abscess of the Liver.—W. C. Quinby reports a case of single abscess occurring in the left lobe of the liver of which the only primary symptom was very rapid loss of weight and strength. To this was added pain, when the thinning of the abscess wall caused the peritoneum to become involved. The discomfort following food, deep breathing, and stooping over is explained in a purely mechanical way through the presence of this adhesion. Etiological factors such as residence in the tropics or a suppurative focus elsewhere in the body were entirely absent. That the abscess had existed for a considerable period before the patient became aware of it was probable both on account of its size and the sterile nature of its contents, but that it could have been present for a year as a sequel to an infection of the hand seemed hardly credible. Its pyogenic nature seemed established beyond a doubt because of the freedom from any further symptoms during the past year. This would hardly have been the case had a necrotic gumma or a neoplasm been the underlying cause.

Catheter in the Bladder.—W. E. Wilson reports a case

of the disappearance of a catheter in the bladder and its subsequent spontaneous passage.

Two Cases of Renovesical Tuberculosis Treated with the Bacillus Emulsion. J. Pedersen.
Chyluria Containing the *Cercomonas Hominis*. C. Rosenheck and G. L. Rohdenburg.
Phrenology and Its Founder. J. Knott.

Meningomyelitis.—W. M. Leszynsky reports the case of a male, 37 years of age, in whom the objective sensory symptoms were very slight, and the reflexes were completely abolished for four weeks. When the knee jerks returned and became exaggerated, and the Babinski reflex developed and persisted the author was inclined to assume that the lateral columns of the cord had become involved, and would degenerate as a residual condition occasionally observed after acute transverse myelitis. This assumption rendered the prognosis as to complete recovery rather dubious. As to the prognostic value of the Babinski type of plantar response, it is now pretty well conceded that it is a very valuable indication of involvement of the pyramidal tract in some part of its course. But its presence cannot always be accepted as significant of pyramidal degeneration. The author has seen it quite frequently as a transient symptom after head injuries, and has also noted its presence, disappearance, and return in the course of brain tumor cases, probably as a result of fluctuation in the intraventricular pressure. Cases of myelitis are on record in which complete recovery has taken place, but they are exceedingly rare. They have usually been either of a mild or atypical character, or of the type associated with or following some acute infectious disease.

Soap and Cholesterin in the Tonsils.—J. Wright has chosen to associate the soaps with the study of cholesterin, because in the tonsil, morphologically and tinctorially at least, they seem to be inextricably associated with it. It seems very clear that through the fatty acids the soap is derived from the neutral fat, but there is some reason to believe that in some way the process, in the laboratory of the cell, is also reversed, because after emulsion it is supposed that the neutral fat assumes the form of soap before it can be taken up through cell membranes, in the intestine and elsewhere; yet within the cell it again answers to the tinctorial and chemical reactions for neutral fat, which apparently under the terms of experiment is inert as regards osmosis, by which for the most part nutritive material finds its way into the cell.

Neurofibromatosis.—W. B. Trimble reports eight cases of this condition, which is also known as fibroma molluscum, or Von Recklinghausen's disease. He states that fibroma molluscum presents a strange picture. The great number of cutaneous outshoots in the form of small tumors, some hard, but most of them soft, some hanging baglike, with an occasional large fibroma mingled with the areas of pigmentation, renders the patient a hideous sight and it is the more deplorable because the malady has baffled medical science these many years, and as yet no light is thrown on the condition from a therapeutic point of view. One interesting feature in connection with this disease is that of heredity. Two of the cases reported by the author were mother and daughter, and the lesions began to develop in both of them at the age of 16. Other observers have made mention of similar instances, when the disease appeared in the children of parents suffering from fibromatosis. Another point to be made here is that cases of this nature are by no means as rare as the literature would lead one to believe. The author is convinced of the fact that there is a goodly number in New York.

Virus of Yellow Fever, Dengue, and Pappataci Fever.—C. F. Craig, in reviewing the work which has been done upon the nature of the virus of yellow fever, dengue, and pappataci fever, is impressed with the similarity existing between them, a similarity which points to the close relationship of the causative organisms. Clinically there is considerable resemblance, all three diseases having a sudden onset, running a comparatively rapid course, and terminating by crisis rather than by lysis. In all three the cause is present in the blood, but only during certain periods; in yellow fever during the first three days of the disease; in pappataci fever during the first day; and in dengue, so far as is known, during the third and fourth days of the attack. In all the injection of unfiltered blood produces the disease. In yellow fever the average period of incubation is three days, twelve hours; in dengue, three days, fourteen hours; and in pappataci fever, three days, eighteen hours. In all the injection of filtered blood produces the disease. In yellow fever the average period of incubation being two days, fifteen hours; in dengue, two days, fourteen hours; and in pappataci fever, four days, sixteen hours. All three of the fevers are transmitted by an insect; in two, yellow fever and dengue, by a mosquito, and in pappataci fever by a biting fly. In yellow fever and pappataci fever the causative agent undergoes a cycle of development within the transmitting insect, while in dengue this point is still undetermined. In yellow fever the mosquito does not become infective until twelve days after it has bitten the infected individual, while in pappataci fever the fly does not become infective for from seven to ten days. In yellow fever the average period of incubation after the bite of the infected insect is three days, eighteen hours; in dengue, four days, eighteen hours; and in pappataci fever, five days, twenty hours. In all three diseases the causative agent is ultramicroscopic in size, as it passes through the best filters that can be obtained, and because the most careful examinations of the blood both microscopically and culturally have failed to show any parasite. In addition, there is conclusive evidence that these diseases are not contagious.

The Doctor and the Church.—C. E. Nammack states that if the lifting up of man from the degradation of alcoholism and poverty, the raising of woman from the ruin brought on by starvation forcing her to vice, and the elevation of children from physical and spiritual darkness into the light—if these, with the other tasks of the physician, do not make a divine vocation, then no life is a vocation, and nothing is divine. "Sick people show to doctors things as they are; the mask is torn off, the facts remain. They show him their life records, ranging from purest white to the most nauseating black, and they expect from him something more than advice and physic." They expect from him sympathy with their sorrows, hope for their despair, charity for their faults, and gentleness with their sufferings. The doctor cannot dispense these unless they are already formed in his own character.

Renovesical Tuberculosis.—J. Pedersen reports two cases of this condition successfully treated with the bacillus emulsion.

Chyluria from Cercomonas Hominis.—C. Rosenheck and G. L. Rohdenburg state that the cases of chyluria may be divided into parasitic and nonparasitic. As to the etiology of the nonparasitic cases practically nothing is known. The parasitic causes are several, the chief one being the filaria. Other parasites which have been reported have been found only in scattered cases. The case reported by the authors is of singular interest in that the parasite itself is not very common in the human family. A fairly thorough search of the literature has failed to reveal a case in which this parasite has been

found in chyluria. The case was one of chyluria occurring in a young negro who had been a resident of New York City for the past two years. The chyluria appeared two weeks after an illicit intercourse. Examinations of the urine showed as the averages of several examinations: Color, white to bright red; specific gravity, from 1.028 to 1.034; reaction, alkaline; no odor, albumin present in large amount; no sugar. Microscopical examination showed no casts, a few bladder cells, no kidney cells, many very finely divided fat globules, and a moderate number of white cells. A differential count of the white blood cells showed polynuclears, 30 per cent.; lymphocytes, 57 per cent.; large mononuclears, 5 per cent.; cosinophiles, 8 per cent. In the fresh specimen during the first two days of the disease there could be seen a moderate number of the *Cercomonas hominis*. As the disease progressed these became less and less frequent, until at the end of two weeks they could no longer be found. The parasites were ovoid in shape and from one pole projected a filament about half as long as the body of the cell, while from the other pole there projected a short spine-like process. While the parasite *Cercomonas hominis* is not infrequent in man and often in a region distant from the alimentary tract, still the probable mode of infection via the genitals in this case is, to say the least, unique. Again the fact that the parasites have at the present time disappeared from the urine raises the issue if this may not be the explanation of the cases of nonparasitic chyluria. It is certain that looking at the case at the present time it would be classed as nonparasitic, there being no parasites present and the cosinophilia having disappeared although the chyluria still persists.

Phrenology.—J. Knott continues his article on this subject.

Shortening of Round Ligaments.—By F. F. Simpson. See Medical Record, Vol. 77, page 1075.

Technique of Esophagoscopy.—By H. S. Plummer. See Medical Record, Vol. 77, page 1107.

Technique for Removal of Appendix.—C. A. Roeder proposes a technique which he claims is simpler than the average and does away with the possibility of postoperative adhesions. Its essential features are a single purse-string, fine linen suture which is not cut until the operation is finished. The suture, in passing from one side of the mesentery to the other, passes through the external coat of the base of the appendix on its mesenteric border in order to embrace an artery that might run along the surface, which will be inside the purse-string after the crushed stump of the appendix is inverted; no area of cecum is ever uncovered by peritoneum; this does away with suturing the peritoneum over the bowel as in other procedures. A second purse-string, continued from the first, inverts the stump of the ligated mesentery with its artery and buries the knot, leaving a perfectly clean peritoneum behind. This second purse-string relieves tension on the first from postoperative gas.

Salvarsan.—B. C. Corbus concludes as follows: One has in Ehrlich's remedy a powerful agent against syphilis. A single injection has in favorable cases approximately the same result as four to five months' treatment with mercury and iodine. It may show a brilliant effect when mercury and iodine have failed. Salvarsan has advanced the treatment of syphilis in a decided manner, but, on account of its strong arsenic content, repeated doses may have a disastrous effect on the human organism. Every physician should master the technique before attempting to use it. Only in this way will the drug be safely guarded from many pitfalls.

Intraperitoneal Shortening of Round Ligaments.—By A. Goldspohn. See Medical Record, Vol. 77, page 1075.

Immunology.—F. P. Gay states that the individual type of natural immunity is seen by the escape of certain individuals from infection under the same conditions as others who suffer from it. Natural racial immunity is, in all probability, dependent on differences in food and general hygiene, and species immunity can be attributed in a general way to differences in metabolism, body temperature, intestinal enzymes, etc. The immunity acquired through recovery from any given disease is, however, of the most significance, and Jenner's discovery of vaccination is the most familiar instance. No generalized conception of the principles existed until the beginnings of the science of bacteriology under Pasteur and Koch, and immunology may be regarded as having become a specialized science from the moment that effective attempts to explain the physiological mechanism of the protection were made. It remained for Metchnikoff to give the first experimental evidence explanatory of the process of immunity by phagocytosis. It is generally admitted now that many forms of natural immunity are best explained on a simple phagocytic basis. The small microphages in the blood are practically concerned with making away with the bacteria which produce acute infections while the larger microphages take up other animal cells, such as red blood corpuscles and protozoa, and also certain bacteria, such as those of tuberculosis and leprosy, which produce chronic infections. The author reviews the controversy in regard to phagocytosis, immunity from toxins, and Pfeffer's phenomenon as explained by Bordet, and offers the following summary as consistent with the facts and a simple explanation of anti-infectious immunity. Bacteria are destroyed in the body of an immune animal by the action of two substances: the sensitizer which is the specific result of immunization and which lies free in the plasma, and the alexin which under usual conditions in the body lies within the phagocyte. If phagocytosis has taken place the alexin works *in situ;* if phagolysis occurs the alexin is liberated and acts in the fluid extracellularly. There is further reason to believe that the more potent the sensitizer the more likely it is that phagolysis should occur. *In vitro* the bacteria are similarly destroyed except that, with fresh serum employed, free alexin is the rule. When the alexin has been retained in the phagocyte as with opsonin experiments the destruction is intracellular subsequent to phagocytosis. That normal opsonins are apparently thermolabile is because the normal extracellular alexin is destroyed and the normal opsonin sensitizer is not sufficiently potent to draw out the intracellular alexins or to cause the opsonized bacterium to be drawn within the cells. The loss of the extracellular alexin is immaterial, however, in the case of immune opsonins and bacteriotropins, as this strong sensitizing power either makes use of a trace of alexin liberated by the phagocytes or else suffices to draw the treated bacteria within the cell. Mention is made of the artificial hemolysins and of the hope that specific immune serums for other animal cells could be produced, especially for the treatment of malignant growths. The general conception, however, now is that the artificial hemolysins are specific for any cell of the species that has furnished the antigenic tissue, rather than for any specific type of cell.

Transfusion in Pellagra.—H. P. Cole describes the results in twenty cases of pellagra treated by transfusion of blood. The patients were all in advanced stages or had been resistant to other recognized methods of treatment which had been fully tried in all. Of the twenty, seventeen recovered, and the author credits the transfusion with these. The larger proportion of the recovered patients were females (68.8 per cent.). One relapsing patient was in an institution, constantly exposed to other cases, and may, the author thinks, be considered as a reinfection. His conclusions are given as follows: In transfusion in twenty cases of pellagra there was no ill effect resulting to the patients directly from the operation. One may safely resort to transfusion in the severe type of case, steadily retrogressing under approved therapeutic procedures. There is advantage in the employment of a donor who has recovered from pellagra as compared with the donor who has never had pellagra. There is aparently no advantage in the use of a relative for a donor as compared to the use of a non-relative. The recoveries following transfusion in the grave type of cases (60 per cent.) compare most favorably with the recoveries (10 to 20 per cent.) in the same type of cases in which other therapeutic measures are employed. The employment of transfusion in the terminal stages of pellagra must be undertaken with a full knowledge of the difficulties and dangers of the operation. Without careful selection of the cases and unprejudiced conclusions this procedure will fall into an undeserved ill repute.

Experimental Poliomyelitis.—S. Flexner and P. F. Clark state that what have come to be called abortive cases are coming to be of importance as regards the transmission of the disease. Our knowledge of this class of cases is still very imperfect and some doubts still exist as to their occurrence. They consider it desirable, therefore, to present the evidence bearing on this point. It is possible by neutralization tests to determine whether or not an attack of poliomyelitis has occurred in a given individual whether paralysis has appeared or not. The test is made by mixing the blood-serum with the filtered virus, keeping the mixture at 37° C. for a few hours, and injecting it into a monkey. Normal human serum has no power to neutralize the virus, while serum from recovered cases of poliomyelitis has. This method does not afford a means of diagnosis, but it is of value as showing whether or not an abortive case of the epidemic has occurred. Up to the present, the immunity principles have been found in the blood of men and monkeys who have had the disease and to persist there for several years. They do not find it, however, generally in the cerebrospinal fluid or nervous tissues excepting in the early stages of the disorder. Cushing and Crowe have shown that hexamethylenamin is in part eliminated into the subdural space, and it has therefore been employed to produce disinfection of the cerebrospinal fluid. It has been tried in human cases of poliomyelitis, but it is clearly not a specific. The drug is well borne by monkys and the authors have found that the incubation of the disease is prolonged and the paralysis is prevented in a certain proportion of cases. When the drug is administered by the mouth and immune monkey serum by injection into the subdural space the paralysis can also be prevented and possibly with greater certainty. It has not been yet determined whether in monkeys thus cured there is a greater resistance to reinoculation than in untreated animals to a primary inoculation. Had the multiplication of the virus been entirely suppressed one should not expect to find any increased resistance. In immune serum protection the susceptibility to reinfection is about equal to that shown by untreated animals. It is important to know that the drug control of the virus of poliomyelitis within the body is a possibility, and also to learn that the successful results have been secured by inhibiting infection and not by restraining an already established infection by the virus. The importance of early diagnosis is noted by the authors, and they call attention to the fact they have ascertained that, instead of being clear, the cerebrospinal fluid shows a very slight turbidity or opalescence at the height of the disease and an excess of protein matter.

Cultivation in Vitro of Rat Sarcoma.—R. A. Lambert and F. M. Hanes state that sarcoma growing *in vitro* may be readily grown in subcultures by transferring the original piece or a portion of the outgrowth to new plasma. Prolongation of life seems dependent only on the renewal of the medium. They have specimens growing at present which have been subcultured in this manner five times at intervals of two to four days. The plasma used was obtained from normal and immune animals, and the growth was as vigorous in the one as in the other.

Arsenic in Syphilis.—A. Hertzfeld states that in cases of inveterate syphilis, which responded no longer to mercury, he has used successfully a solution of arsenic, which consists of 1 gram arsenic trioxide and 2.25 c.c. normal soda solution in 100 c.c. of distilled water, representing a 1 per cent. solution of sodium arsenite, a solution which is very slightly alkaline. Its subcutaneous injection does not cause more inconvenience than an injection of morphine; its intramuscular injection is painless. Lately he has used the intramuscular method (glutei) exclusively, and has given these injections hundreds of times and has never seen even the slightest tendency to suppuration. The skin before injection is disinfected with an alcoholic solution of iodine and potassium iodide and the site of injection is sealed with a mixture of this idodine solution with tincture of benzoin in the proportion of 1 to 4.

Weak Medical Schools.—H. S. Pritchett restates some of the reasons recently given in the "Report on Medical Education in the United States and Canada" to show that certain schools are to-day hindering, not helping, the cause of medicine.

John Hunter and His Museum.—E. Owen states, among other things, that Hunter was at work in his museum from dawn till breakfast; and he was in his consulting room or in his carriage, and visiting his hospital or his private patients, from breakfast till dinner—which he took, according to the custom of the day, at 4 o'clock. After dinner he went to sleep for an hour, and then sat down to write letters and essays, to work up clinical records, or to describe preparations for his museum. At midnight the butler brought him in a fresh lamp, by the light of which he continued to work on till 1 or 2 in the morning, or even later in winter. So that, including the nap which he had after dinner, he was apt to get but four or five hours' sleep out of the twenty-four. We are plainly told that he had no home amusements, and that he took his greatest pleasure among the wild animals which he kept in the garden of his house in Earl's Court, where he slept, and where, with his family, he spent the greater part of his time in the autumn months. What a life to live! Which of us would accept it, even to be, as Hunter is, immortal? But Nature, ever jealous, could not pardon even him, her devout and loving disciple, for so long and complete a neglect of her unwritten laws. As far as one can make out he took no bodily exercise, and sought little mental relaxation The bow was never un-

strung. There is little to suggest that outside of the science and practice of his profession Hunter found much to interest him. The letters which he wrote and received or, at any rate, those of them which have been preserved and published, make no allusion to sport or pastime; and there is no mention of foreign travel, that delightful relaxation for a busy man with no special interest in the pleasures of country life. Indeed, Hunter's one and only happiness was in intellectual work, and especially in that which concerned his museum. Every medical man should make for himself interests outside of his profession to which he can devote himself in the odd times in which he can escape from the anxieties of his occupation. Intemperance in work is well-nigh as harmful as intemperance in eating or in drinking. In the absence of outside interests a medical man is truly to be pitied. When, with advancing years, he unwillingly retires from the contest, if there is nothing better for him to do than to look wistfully backward or sorrowfully forward the evening of his life must, indeed, be dark and miserable. But happily there was no evening to Hunter's life; he died before the lengthening shadows fell across his path.

Operations for Stone in the Male Bladder.—W. F. Haslam in his first lecture on this subject gives the history of operations for calculi, stating that these had been performed for over 2,000 years.

Sphygmomanometer and Sphygmograph.—C. O. Hawthorne states that these two instruments not only are not, but cannot possibly be, mutually contradictory, for they speak not of the same, but of two different and independent things—the one of the level to which for an undefined period of time the blood pressure rises, the other of the relative duration of the pressure and of the manner of its decline. Each has its own value, each has its own function, and the information obtained from the one supplements that conveyed by the other; but the activities of these instruments are displayed, not on the same, but on different planes, and therefore cannot possibly come into mutual conflict and collision. It must be added that even when sphygmomanometer and sphygmograph have both been employed there still exists a deficiency in our instrumental appreciation of the qualities of blood pressure, as neither of these instruments records the minimum level to which the intraarterial pressure falls. To measure this so-called diastolic pressure many methods have been suggested, but none of them can be accepted with complete confidence, and the absence of this measurement lends emphasis to what is implied in the argument of the author's address—namely, that the customary announcement of the maximum sphygmomanometric figure on the one hand, or the presentation of a sphygmogram on the other, is in the individual patient anything but a complete, final, and exhaustive statement on the clinical aspects of blood pressure.

Eyestrain in Relation to General Health.—J. Hinshelwood describes the following conditions that may result from eyestrain: headache, insomnia, neurasthenia, choreiform movements of the facial muscles, vertigo, and dyspepsia.

Diffuse Latent Labyrinthitis.—J. Harper states that Bárány has shown that if an ear with a healthy labyrinth be syringed with cold water there occurs a nystagmus toward the other side, while if hot water be used—*i.e.*, water above the temperature of the body—there occurs a nystagmus to the same side. This is brought about by causing a cooling or a heating of the endolymph in the canal which is nearest the water, thereby setting up a flow in the fluid which is necessarily microscopic. This is called the caloric test. Various other phenomena accompany this nystagmus—giddiness, disturbance of equilibrium, and nausea, but these only usually occur if the rotation or syringing be continued too long. The nystagmus is the first and most constant symptom to appear, and it is on it that one relies for any diagnostic value. There are two conditions in which the caloric test cannot be used—namely, where masses of cholesteatoma fill up the cavity of the middle ear, or where the external meatus is so constricted as to hinder the passage of a stream of water. The practical utility of these two tests is obvious. Should the labyrinth be destroyed by trauma or disease, on their application there will be no resultant nystagmus from the diseased ear. The author draws attention to the grave danger of operating on the mastoid before having tested the condition of the labyrinth. The caloric test is simple and easy of application, and all cases, before being submitted to operation, should have this test applied to them. The labyrinth operation can be undertaken with a great degree of safety, and where the labyrinth is found to be affected either by acute suppurative labyrinthitis or latent labyrinthitis, this operation must be performed in addition to the radical mastoid operation. In the lesser degrees of labyrinthine involvement the radical operation should be performed, but a careful watch must be kept on the labyrinth, and should the case progress to the acute suppurative type the labyrinth operation must be undertaken at once. Long-standing cases of chronic middle-ear suppuration should always be examined for latent labyrinthitis. If the caloric test be made a routine practice in all cases such as have been described, then the untoward results after operation will become rare and the number of brain complications from aural suppuration will be greatly decreased.

X-Ray Treatment of Ringworm.—S. E. Dore concludes that there are two points upon which he would lay stress. In the first place, if the *x*-ray treatment is to be successful, it must be conducted in a methodical and systematic manner, by a trained operator and under skilled supervision; the child's head should be carefully and accurately marked out with a blue pencil before the treatment is begun, and the patient and apparatus should be watched during the whole time the child is under the rays. Secondly, the operator must not be stinted as regards efficient tubes and apparatus; the excessive use of one tube is false economy and may be dangerous, and such appliances as the milliamperemeter for measuring the current in the secondary, the valve-tube for checking the reverse current, the spark-gap for testing the resistance of the tube, etc., are additional safeguards. The cases of permanent baldness the author has seen have been, for the most part, due to the employment of an unskilled or careless operator or to the use of unsuitable tubes.

Operations for Stone in Male Bladder.—See abstracts of articles in the *Lancet*.

Chronic Subcutaneous Fibrosis.—R. Stockman concludes that chronic inflammation of the subcutaneous connective tissue is a very common affection. It is secondary to various acute and chronic infections. The implication of the small peripheral nerves in the chronic inflammatory process gives rise to sensations of aching, stiffness, numbness, fatigue, etc. When persons already stout or who

afterward become so are affected as above, the fat tends to form larger or smaller masses round the hypertrophied connective tissue. These masses are often very painful on pressure owing to the nerve twigs being in a condition of interstitial neuritis. The fatty masses are deposited mostly in the ordinary situations of fat accumulation. The condition described by Dercum as "adiposis dolorosa" cannot be ranked as a special disease. Cases of subcutaneous fibrosis can be treated with a considerable degree of success if treatment is gone about in the proper way and is persevered in. In thin people one has to rely on massage, daily exercises, directed to stretch the altered fibrous tissue and to accustom it to movement, along with an habitually active and as far as possible open-air life. If all this is systematically carried out for some months the inflamed fibrous tissues gradually lose their extreme liability to become painful on exertion or exposure to cold and wet, and the patient is restored to comparatively good health. Some cases get practically well, many are improved, and in all considerable benefit is assured. An habitually active mode of life with plenty of outdoor exercise is necessary to maintain the improvement. The massage must be given firmly and so as to reach the affected parts. It is always painful at first, and should be given only by those who have had experience of similar cases. What probably happens is that the massage lessens or gets rid of the local neuritis, and favorably affects the inflamed small blood-vessels, so that exudation is not apt to occur from them. It is commonly said to act by improving the flow of blood and lymph locally, but there is no exact knowledge on these points. In stout or plump people the principles of treatment are the same, but in them one has to deal with two distinct conditions—the fatness and the chronic fibrosis. The inflamed fibrous tissue is relatively in very small amount compared to the fat round about it, and, thus embedded, it is a hopeless business to try and reach it and its inflamed nerves and vessels by means of massage. Massage under such conditions is quite ineffective, and often unbearably painful. The first step in treatment is to get rid of the superabundant fat, and this is best accomplished by a more or less strict diabetic diet, and the administration of thyroid gland. Exercises can be commenced at once and massage somewhat later. The paroxysmal pains often disappear or greatly lessen as the fat becomes absorbed.

Leucocytic Extract in Infective Processes.—D. M. Alexander reports a series of ten cases in which leucocytic extract was used. These cases do not present any striking successes at first sight. Two factors have militated against more encouraging results: 1. Several of the cases have been handed over for treatment in a hopeless condition. 2. It is difficult to obtain permission to persevere with the treatment. In some cases it is absolutely necessary to push the administration of the leucocytic extract, and the patient occasionally rebels although the temperature chart and the general condition witness an improvement. Thus cases which began to improve were lost. The injections were given into the flank or into the buttock. No attempt was made to approximate the site of injection to the infected part. Pettersson, Hiss, and Zinsser have demonstrated bactericidal and bacteriolytic properties in leucocytic extracts *in vitro*. They agree that the power is not great and quite inadequate to account for the destruction of large doses of the bacillus of anthrax, which were administered in the guinea-pig experiments. They at first considered that the leucocytes supplied complement to the infected organism; for Metchnikoff has claimed that the cytases (complement) are not normally free in the plasma, but are contained in the leucocytes and only given up by them under stress of death or injury. But they have not been able to prove the presence of complement in their extracts. Kling, however, has recently published experiments which may ultimately show that leucocytic extracts possess the power of reactivating serum, even leucocytic extract itself which has been inactivated by heat. The body which has this power is not identical with the complement of the serum, since it withstands heat at 70-75° C., whereas the serum alexine is readily destroyed at 56° C. Pettersson, Hiss, and Zinsser finally agree in the history of endolysins. Hiss and Zinsser say that the beneficial effects obtained by the administration of leucocyte extracts are due to the action of digestive substances usually not liberated from the leucocytes, to poison-neutralizing or destroying bodies, which act on the endotoxins and thus relieve the leucocytes of the animal from fatal poisoning and protect the higher cells of the animal so that their functions are not deranged. Whether these theories be correct the author has found that a marked leucocytosis followed an injection—a phenomenon not mentioned by other workers. Hiss and Zinsser give figures of blood counts in some of their cases of pneumonia, but these are in relation to the crisis and not to the injections. Floyd and Lucas state that a study of the white count has frequently shown a steady diminution in the number of leucocytes present in the peripheral circulation following the beginning of inoculation until the termination of the disease, possibly suggesting a diminished demand upon their reproduction with the addition of the extract.

Electricity in Neurasthenia.—J. Metcalfe reports a series of eight cases of neurasthenia in which the usual methods of treatment had failed, and in which the application of electricity produced good results. It will naturally be asked, how do the electrical currents act physiologically so as to cause the improvement as seen in this class of case? Psychical effects may be produced at times by these methods, as may happen in every other form of treatment. But improvement and cure must in a series of cases be due, as in other methods, to powerful therapeutical effects. In cases in which the blood pressure is high the effect of reduction of arterial tension may in itslf produce the result. In the use of electrical machines there is always a large amount of ozone generated and it is not impossible that the inhalation of this gas for half an hour at a time may have some power of improving the patient's condition. D'Arsonval and others have demonstrated increased tissue changes, more rapid reduction of the oxyhemoglobin in the blood, and increased elimination of waste products in the urine. Not only the sympathetic nerves controlling the vasomotor system, but also those controlling the secretory, the thermogenic, and the peristaltic functions are stimulated. There is a profound action on the protoplasm of cells everywhere, increasing their chemical changes. Usually an increased amount of urea is excreted, attended by a disappearance of uric acid showing the oxidation of nitrogenous material. It is said that the output of CO_2 is sometimes increased from 17 to 37 liters an hour, and that there may be an increase in heat production from 79 to 127 calories an hour.

Simulated Disease.—J. Ewens reports five cases of simulated disease occurring in persons of hysterical or neurotic temperament.

Eucalyptus Oil Poisoning.—W. E. Foggie states that eucalyptus oil, as used within its usual dose limits of ½ to 3 minims, seems never to give rise to any toxic symptoms, but a remedy such as this, which has almost become a household standby for catarrh and the like, has, in not a few cases, been taken by mistake in larger doses, and in some cases with poisonous effect. The number of such cases is as yet but small (in fact scarcely over a dozen) and their record is naturally fragmentary, as all notes of poisoning are apt to be when the necessity of therapeutic measures must perforce prevent detailed study of the resulting clinical phenomena. In these cases of eucalyptus poisoning the symptoms have varied greatly according to the amount of oil taken, and apparently also according to

the idiosyncrasies of the patient. Incidentally it may be mentioned that Davies knew a patient who fainted even with the smell of it. In general, toxic symptoms have been noted after doses of 1 dram or more, but H. S. Taylor speaks of a patient who felt a little giddiness and confusion after ½ dram. Most of the cases, however, developed marked toxic symptoms after doses of 1 dram or more. With such different dosage the time of onset of toxic symptoms has naturally varied greatly—from ten minutes in one case to one or two hours in another. In like manner the kind of symptoms and the order of their development have shown differences. Vomiting was generally the first sign, and it was frequently followed by abdominal pain and diarrhea. In most of the cases, whether preceded by gastrointestinal irritation or not, unconsciousness, varying in degree from mere drowsiness to coma, supervened. In some the first symptom noticed was a giddiness. In all but the slightest cases further effects manifested themselves in pallor, quick pulse, and general collapse, as well as frequently respiratory disturbance. No after effects were noted beyond the temporary odor of the breath.

Salvarsan in Frambesia.—H. Alston notes the improvement that occurred in five cases of yaws treated by means of injections of salvarsan, the yaws tubercles drying up from the periphery, so that whitish circles appeared to be surrounding them. The author tried an experiment. He had read that in the case of an injected syphilitic mother and suckling the baby was cured by suckling the mother, and he was also aware of Ehrlich's view that 606 created an antibody by rapidly destroying spirochetes. He therefore put a cantharides blister on two of the cases being cured by the 606 treatment, and injected the serum from the blister into several cases of yaws, the adult dose being 16 c.c. To his astonishment, the serum acted as rapidly as 606. In some cases improvement was noticed in sixteen hours after injection. He injected thirteen more cases of yaws with 606, and the same rapid improvement was noticeable—in some cases as early as sixteen hours after. The author applied fly blisters to some of these cases and used the serum for more experiments. In every case injected with serum there was a rapid improvement. The author believes that this is the first instance known of a drug producing an antitoxic serum with curative properties, and the effect, in a boy, of injecting 2 drams and 20 minims of a serum that had not been hyperimmunized was very astonishing.

Salvarsan in Syphilis.—E. G. Ffrench describes the favorable results that he obtained with this remedy in three cases, the first to be so treated in India.

Berliner klinische Wochenschrift.

February 13, 1911.

Treatment of Morphinism.—Schroeder takes issue with the majority of practitioners in claiming that abstinence phenomena are not as a rule to be feared in sudden withdrawal of the drug in the treatment of drug addictions. Many great authorities, such as Kraepelin, depict the results of sudden withdrawal in the most somber hues. Delirium, heart failure, collapse, and impending death are treated of as consequences to be anticipated, provided the addiction has reached a certain degree. Others, like the author, admit the existence of such phenomena in individual cases, but add that there must be special reasons for the sequence, which need not necessarily apply to the bulk of patients. The petty symptoms of sudden withdrawal—restlessness, pains, exhaustion, chills, sneezing, yawning, diarrhea, insomnia, etc.—may not be more marked than when the withdrawal is gradual. In the Breslau Psychiatric Clinic abrupt withdrawal has now been the rule for some years, and alarming symptoms have not been noted. Naturally the morphine is replaced by other substances which do not conduce to habit formation, as veronal and hyoscin, and by psychotherapy. The patients may protest vigorously against the withdrawal, but this is to be expected. Decided improvement is noted inside of a week. In certain cases the patients before admission had used cocaine, heroin, dionin, atropine, etc., in addition to morphine. The management of morphinism does not differ greatly from that of alcoholism. The author does not regard the former as much more serious than the latter.

Albumin Reaction in the Sputum and Its Significance.—Gantz and Hertz dilate on the relative neglect of the albumin reaction in the sputum on the part of diagnosticians. This is obtained by freeing the sputum in any pulmonary affection of such constituents as mucin, nucleoalbumin, blood, etc. The result is obtained by treating the undiluted sputum with acetic acid and filtering. The filtrate is then boiled, and it may be necessary to neutralize excess acid with potassic hydrate. In regard to the significance of the albumin when found, the latter is constantly present in inflammatory pulmonary affections and edema, but is always absent in bronchitis These two axioms cover almost the whole of pulmonary, including bronchial, lesions. Thus tuberculosis, in so far as it is inflammatory, gives a positive result in any stage. Fibroid phthisis doubtless constitutes an exception.

What Becomes of the Tuberculin Formed in the Body?—Geszti believes that the tuberculin formed in the body in tuberculosis confers no immunity, but instead renders the patient supersensitive—referring to cases of the disease which have healed spontaneously. In other words, antibodies which have formed to defend the organism, while they may have done this work and arrested the disease, have nevertheless been neutralized by the tuberculin formed in the body. Such cases of spontaneous recovery, which are extremely numerous, give a stormy reaction when injected with tuberculin formed from cultures outside of the body. The tuberculin formed inside the body does not cause any reaction at all in these cured cases. What changes it undergoes and how it may be neutralized the author hopes to determine in the future.

Reciprocal Action of Internal Secretions.—Balint and Molnar have made some experiments intended to throw light on this subject. The frog's eye constituted one test, while another was the behavior of the extracts with strychnine. Adrenalin does not (!) dilate the frog's pupil, while the thyroid and pancreatic expressed juices are inert in this respect. In a certain dilution of adrenalin it was sensibilized by the thyroid extract, while pancreatic extract had a paralyzing action under the same circumstances. Both thyroid extract and adrenalin negatived the action of strychnine. Pancreatic extract had no direct action on strychnine, but by antidoting the action of thyroid extract and adrenalin enabled the strychnine to exert its natural action.

Münchener medizinische Wochenschrift.

Influence of Appetite on the Activity of the Stomach.—Fischer makes use of what he terms an appetite breakfast, which within certain limits is left to the patient's choice. The latter may choose between the following beverages: milk, coffee, tea, bouillon, thin lemonade—of each 300 c.c. He may take 75 grams bread or roll with 20 grams butter. Finally, he may select between scraped beef, ham, cervelat sausage, grilled herring, or two eggs. This differs from the trial breakfast in that the selection of food is determined largely by the patient's tastes. Control patients were given a breakfast of the doctor's own selection and without regard to the patient's tastes. The stomach contents were siphoned out at stated intervals.

The experiments were made in part to test the doctrines of Pawlow concerning appetite gastric juice. The results obtained were as follows: The appetite breakfast gives a better idea of the motor and secretory activity of the stomach than does the old trial breakfast. The latter, however, should also be used in suspected cancer of the stomach. The trial breakfast selected without reference to the patient's tastes is often repugnant, and cannot give the desired information as to the patient's gastric activities.

Prognostic Significance of the Entrance of Germs into the Blood.—Sachs introduces his subject with a reference to the so-called hemolytic streptococci which have of late years drawn the attention of gynecologists and obstetricians. We have here a germ capable of a direct destructive action in the blood stream, and doubtless not to be confused with nonhemolytic streptococci, which may chance to be absorbed. The subject in question is by no means confined to puerperal fever. The author cites a case of cancer of the cervix in which hemolytic cocci were found in the vaginal secretions. Total ablation of the uterus, etc., was performed (Wertheim's radical operation). The woman died on the fourth day of peritonitis, yet none of the cocci could be recovered from the blood. This opens up a side subject, viz., that certain cases of peritonitis are sufficient to cause death without any prior or subsequent implication of the blood. Such cases remain strictly localized, from first to last. The peritoneal exudate or pus contains the hemolytic streptococcus. Such cases are not uncommonly seen in connection with "septic" abortion (falsely so-called). In order for the streptococci to attain such virulence as to multiply in the blood, the element of time must be considered. In other words, it is rather in cases of some duration that we have heretofore recovered virulent germs from the blood. We are at present interested in the question of when and how germs first enter the blood and how this act may be recognized. Direct absorption of germs is not a practicable hypothesis. Ulceration into a venule or a primary phlebitis leading to an infected thrombus are known methods of propagation of bacteria into the circulation. Once a lesion like endocarditis is set up, we have a ready explanation of the future entrance of germs into the bloodstream. In so-called putrid abortion, a sapremia is set up and a saprophytic, nonhemolytic streptococcus may enter the blood, causing mild symptoms. The author's paper raises questions without answering them. It is written in a very desultory fashion and no conclusions are appended.

Collateral Effects of Salvarsan.—Gilbert of Munich and Sellei of Budapest each make contributions to this subject. The former reports a case of presumable syphilitic meningitis in which an injection of salvarsan caused epileptiform convulsions which were a part of the general reaction. A somewhat similar case had been placed on record. It would appear that meningitis from its proximity to the cortex might prove a contraindication to the use of the drug, for a severe general reaction tends to affect the tissues near the lesion. Sellei relates a number of cases in which mild collateral effects were attributable to salvarsan, but none were severe enough to furnish contraindications. Once an organ has been attacked by syphilis the general reaction from salvarsan may be severe enough to set up symptoms in or near the affected tissues. This excessive reaction must be set down to supersensitiveness.

Deutsche medizinische Wochenschrift.

February 16, 1911.

Puerperal Autoinfection.—Ahlfeld, for many years the protagonist of the autogenous origin of at least a very large proportion of sporadic cases of puerperal sepsis, claims that his views are constantly gaining support, although at the same time strengthening the opposition, who see in it a return to the old doctrines which were exploded by Semmelweiss. But even the latter records cases of self-infection, in the sense that a woman might be infected from her own soiled linen. The theme of autogenous infection is a very wide one and includes everything not comprised under heteroinfection, *i.e.* by fingers and instruments contaminated by the secretions of another person, or by germs of a virulent character accidentally conveyed to the patient by some lack of cleanliness. If a woman infects herself with her own soiled fingers this would not be a form of autoinfection. The author is very particular as to this point. An autogenous infection might arise from a preexisting lesion in the genital tract, and even from a distant purulent focus, in the latter case representing a so-called cryptogenous sepsis. Of more general significance is the emigration of vulval germs into the upper vagina or the conveyance of the same to the latter by the examining finger or instruments. The number of varieties of presumable self-infection is a large one; at least, a score of such possibilities have been considered by von Herff and Walthard.

Herpes Zoster and Renal Colic.—Bittorf cites a case as an example of the ability of an internal lesion to cause a zoster in the corresponding Head's zone. The discovery is by no means new, for Quincke made a similar announcement in 1890. The lesion which precipitates the zoster must be a painful one. The eruption may be preceded by paresthetic sensations, hyperalgesia, etc., as is the case with zoster from any cause. The same subjective phenomena may occur from the same causes without the development of zoster. Gastric ulcer sets up hyperalgesia between the sixth and ninth dorsal segments. Disease of the aorta produces hyperalgesia in the ulnar aspect of the left forearm, etc.

Ultraradical Operation for Cancer of the Cervix.—Seeligmann would always employ the Wertheim-Bumm operation as the procedure of choice in cancer of any part of the uterus, including the cervix. This involves laparotomy in every case, because the removal of lymph nodes, parametria, etc., is thereby facilitated. The chief drawback is the operative mortality. The operation must be performed as rapidly as possible and should not last over an hour and a half. It has been proposed to employ an abdominovaginal method in certain cases for the sake of better drainage. The operation is not contraindicated even in the most desperate cases with involvement of the rectum and bladder.

Iodism and Thyroidism.—The correlation between these conditions, which is at present being freely discussed, is reviewed by Berg. He traces the history of our knowledge of the use of potassium iodide, with the discovery of iodism, which occurs not only when the drug is pushed beyond tolerance but also in some individuals from minute doses (iodine idiosyncrasy). The phenomena of iodism show the greatest variety. The author seems unaware that severe iodism from small doses of the drug is due, in some cases at least, not to supersensitiveness *per se* but to defective elimination by the kidneys. Thus some of the worst recorded cases of iododerma tuberosum have occurred in subjects with nephritis or temporary obstruction of the kidneys. Iodine in certain cases can set up the picture of thyroidism, or of Graves' disease. In individuals with goiter it can reduce the size of the latter, although goitrous subjects are often more sensitive to the drug than are normal individuals. On the other hand, the use of iodine may cause a marked engorgement of the gland in connection with the picture of thyroidism, although the latter readily occurs without the former. Iodides given to a syphilitic girl set up a typical Graves' syndrome (no exophthalmus) with a veritable thyroiditis. The complicated relationship between iodism and thyroidism must be connected in some way with the iodine normally present in the thyroid—in some cases to the extent of 8 per cent.

Book Reviews.

THE RACIAL ANATOMY OF THE PHILIPPINE ISLANDERS. Introducing New Methods of Anthropology, and Showing their Application to the Filipinos with a Classification of Human Ears and a Scheme for the Heredity of Anatomical Characters in Man. By ROBERT BENNETT BEAN, B.S., M.D., Associate Professor of Anatomy, Tulane University of Louisiana, New Orleans, La.; formerly Professor of Anatomy, Philippine Medical School, Manila, P. I. With 19 illustrations reproduced from Original Photographs. Seven figures, $2.00. Philadelphia and London: J. B. Lippincott Company, 1910.

THIS book is a valuable contribution to the science of anthropology. It embodies the results of three years' investigation of the Filipinos, and introduces a method of segregating types and comparing different groups of men. The omphalic index is established as a differential factor in racial anatomy. This index is found by dividing the distance of the umbilicus from the pubic spine by its distance from the suprasternal notch. This indicates its relative position in the body. The ear is also established as an index of type. Each type of ear is associated with a physical type of man. The object of the book is to establish definite types of man that may be recognized by ear form, cephalic index, nasal index, and other factors, that such types may be studied in families through several generations, to establish their hereditary characteristics. There is a chapter on the relation of morphology to disease. The author concludes from his investigations that the Filipinos were originally composed largely of two systematic species of men, which he terms Primitive and Australoid. To these have been added Chinese and European elementary species, chiefly Iberian, especially in the cities and along the littoral of the islands. The elementary species represented by the European and Chinese are now in greater abundance than the systematic species, and the Blends constitute about one-half of the littoral population. The Iberians apparently are more liable to tuberculosis, whereas the original Filipinos are comparatively free from the disease. The Iberian will ultimately disappear, leaving new combinations and Blends unlike the original types.

THE PRACTICE OF MEDICINE. A Guide to the Nature, Discrimination and Management of Disease. By A. O. J. KELLY, A.M., M.D., Assistant Professor of Medicine in the University of Pennsylvania, and Assistant Physician to the University Hospital, Philadelphia; Professor of the Theory and Practice of Medicine in the University of Vermont; Professor of Pathology in the Woman's Medical College of Pennsylvania; Physician to St. Agnes' Hospital, Philadelphia; Chief of the Pathological Department of the German Hospital, Philadelphia; Member of the Association of American Physicians and of the Interurban Clinical Club; Editor of the *American Journal of the Medical Sciences*. Illustrated. Philadelphia and New York: Lea and Febiger, 1910.

THIS book is intermediate in size between the many-volumed systems of medicine and the smaller manuals. The points that call for notice are: The arrangement and classification of the diseases, and the various introductory sections on pathological physiology, both of which are excellent; also, the few prescriptions which are given are written out in full and in English. But otherwise the book can hardly be distinguished from the very large number of similar works that have appeared during the last ten or twelve years. Being the most recent, it is naturally the most up to date; but, at times, it is so condensed as to make difficult reading. It will hardly displace the well-known volumes of Tyson, French, Osler, Hare, Anders, and others. Among some of the rarer affections, not usually treated of in works avowedly intended for students and junior practitioners we find Nasha fever, Ponos, Kubisagari, Ainhum, Goundou, and Psittacosis. The Widal reaction is throughout referred to as the Gruber-Widal reaction, and Koplik's spots are called Filatow-Koplik spots; both of these are, of course, accurate, but they are more commonly called by the unhyphenated names.

DISEASES OF THE HEART AND AORTA. By ARTHUR DOUGLASS HIRSCHFELDER, M.D., Associate in Medicine, Johns Hopkins University. With an introductory note by LEWELLYS F. BARKER, M.D., LL.D., Professor of Medicine Johns Hopkins University. Three hundred and twenty-nine illustrations by the author. Philadelphia and London: J. B. Lippincott Company, 1910.

THIS large monograph on heart disease exhibits in its arrangement somewhat of a new departure. The object of the author has been to present side by side the phenomena observed at the bedside and the facts learned in the laboratory in order to show how each supplements the other in teaching us how to observe the patient and to direct the treatment. Consequently, in this work experimental pathology and the basic principles of the subject are discussed ere the clinical details are dealt with. The entire subject of disease of the heart and of the aorta is ably presented. The chapter on arteriosclerosis is deserving of attention, in the treatment of which the author strongly recommends hydrotherapy. Emphasis is laid on the point that syphilis is a very important factor in the causation of arteriosclerosis, especially in that which occurs before the age of thirty-five. Another instructive chapter is the one treating of thyroid heart, and the treatment thereof, therapeutic and operative, is fully debated. The physiology of exercise is interestingly discussed, and although Dr. Hirschfelder does not give a decided opinion as to the best form of exercise with regard to the heart, he does condemn thoracic and abdominal constriction as a factor in cardiac overstrain. The bibliographic references are numerous, as are the illustrations, which are mainly by the author himself.

DIAGNOSTIK DER NERVENKRANKHEITEN, von Dr. L. E. BREGMAN, Oberarzt am städtischen jüdischen Krankenhaus in Warschau. Mit einem Geleitwort von Hofrat Prof. Dr. H. OBERSTEINER, in Wien. Mit 193 Abbildungen und 2 Tabellen. Berlin: Verlag von S. Karger, 1911.

THIS is one of the very latest books on the diagnosis of nervous diseases, and, as it bears the indorsement of the great Obersteiner, the number of whose American pupils is legion, it is bound to receive prompt recognition. It is doubtless based on the latest accepted anatomical and physiological data and embraces the newest discoveries in symptomatology and methods of accurate diagnosis in this most obscure and difficult branch of medicine. For the purposes of the general medical reader, it may be stated that the book is clearly written, conveniently arranged for reference of symptoms, and is authentic. The plan and scope of the work, briefly outlined, are as follows: There are sixteen sections, or chapters, covering 535 pages, and containing 193 illustrations, many of which are original. After a short chapter on case taking, motor disturbances of a paralytic nature are differentiated, followed by chapters on ataxia and tremors, and diseases due to cortical irritation. Disturbances of general sensibility of various types as found in various diseases of nerves, cords, and brain, and including subjective disturbances, are given an interesting chapter. This is followed by consideration, in turn, of disturbances of the reflexes, of the pupils, of the special senses, and of speech and psychic disturbances. The various diseases in which vasomotor, temperature, and trophic disturbances occur are discussed in the twelfth section, while the last four chapters are devoted to disturbances of bladder, rectum, sexual functions, heart, lungs, stomach, etc., occurring in nervous diseases; and to cranial and spinal topography, and lumbar puncture.

ŒDEMA. A Study of the Physiology and the Pathology of Water Absorption by the Living Organism. By MARTIN H. FISCHER, Professor of Pathology in the Oakland School of Medicine, Oakland, Cal. The 1909 Nathan Lewis Hatfield Prize Essay of the College of Physicians of Philadelphia. New York: John Wiley & Sons, 1910.

THIS monograph is an attempt to prove experimentally and clinically that the cause of edema resides in the tissues, or, more specifically, in any condition which leads to the production of acid in the tissues. The experimental work consists in the production of edema in animals and in the study of the behavior of colloids toward surrounding fluids; the clinical data are such as can be deduced from the observation of edema in nephritis, cardiac disease, etc. The monograph is written very convincingly, and is recommended to all actively interested in the explanation of the phenomenon of edema in physiological and pathological states of the organism.

LES FORMES LARVÉES DU PALUDISME. Diagnostic et traitement. Par le Dr. BASILE MOUSSÉOS. Price, francs 3.50. Paris: Vigot Frères, Editeurs, 1910.

IT would seem difficult to add anything to our knowledge of the morphology of the malarial parasites in the blood, but the author of this pamphlet considers that he has discovered new forms in the masked or larval types of malaria. The cuts and descriptions of the organism suggest blood plates, which have unfortunately already done duty as the parasites of syphilis and of Rocky Mountain fever. A large number of clinical observations fill up the text and illustrate the author's ideas on the treatment of this masked type of malaria. He thinks that quinine has nothing to do with hemoglobinemia and believes that the only treatment is by repeated injections of quinine, strychnine, and iron.

The Principles of Gynecology. By W. Blair Bell, B.S., M.D. (Lond.), Assistant Gynecological Surgeon, Royal Infirmary, Liverpool. With 6 colored plates and 357 illustrations in the text. London and New York: Longmans, Green & Co., 1911.

Dr. Bell's book presents several features, both in the material and in its presentation, which distinguish it from similar works on this subject. It is claimed to be addressed to the general practitioner and the student and is designated as a work on the principles of gynecology. Whether it fulfills this function remains to be seen. A great deal of space is devoted to topics which are not usually included in text-books on gynecology and are more appropriately discussed in works on obstetrics. The chapter on the female generative organs traces their development from fishes to man in a manner more complete than would seem to be necessary for a proper understanding of gynecological principles. A great deal of space is also devoted to the physiology of conception and reproduction, including the signs and symptoms of pregnancy. Considerable attention is paid by the author to morbid histology in gynecological diagnosis, and a large number of photomicrographs are shown to supplement the pathological descriptions. It is quite evident that the author is greatly impressed with the close relation between obstetrical and gynecological conditions, for abortion and ectopic gestation, among other things, are fully discussed as regards their primary features as well as their after-effects. The question of operation for gynecological conditions occupies a comparatively small portion of the book, a subject for which the practitioner or student most frequently consults a text-book. Among these operations, abdominal cesarean section is also discussed, but in a brief and most unsatisfactory manner, as only the operation with complete delivery of the uterus is described, a procedure now very rarely employed, if at all. For the cure of uterine prolapse, vaginal fixation or shortening of the uterosacral ligaments is not recommended, and the treatment of ventrifixation is also made to include suspension operations after the manner of Kelly. For the relief of this condition the author advises Gilliam's and similar procedures. In this connection reference may be made to the author's ring retractor, which appears to be a very useful contrivance in abdominal operations. In an appendix is briefly described the subject of electrotherapeutics as applied in gynecological treatment, and its importance in the eyes of the author may be gauged by the fact that this chapter includes but five pages. A more valuable section is that devoted to the classification of the causes of certain symptoms met with in gynecological practice, which is of some interest and value. Taken as a whole, it may be said that Dr. Bell's book presents the general principles of gynecology in a fairly satisfactory manner, with the exceptions previously noted. The printing, binding, and illustrations are excellent.

Chronicles of Pharmacy. By A. C. Wooton. Two volumes. London: Macmillan and Co., Limited, 1910.

This work is a chronology, of course, more or less inclusive and accurate, of pharmacy from very early times. The first chapter deals with the myths of pharmacy, which, it is needless to state, are very numerous. Perhaps the most interesting of such myths is that relating to Morpheus, who derived his name from Morphe (form or shape), from his supposed ability to mimic or assume the form of any individual he desired to pose, as in dreams. Pharmacy in old Egypt is discussed, and it is pointed out that, according to Herodotus, "So wisely was medicine managed in Egypt that no doctor was permitted to practise any but his own branch." That is to say, that doctors were all specialists. They were likewise all priests, although all priests were not physicians. A chapter is devoted to pharmacy of the Bible and the somewhat high standard reached by the Arabs a thousand years or so ago in both pharmacy and chemistry is adequately acknowledged. The history of pharmacy is traced from the Arabs to the Europeans and then a chapter is given up to a consideration of pharmacy in Great Britain. Magic and medicine, dogmas and delusions are touched upon, and a long and instructive chapter treats of masters in pharmacy, while the following chapter contains interesting material concerning certain royal and noble pharmacists. The last portion of the first volume narrates the history of the medicines obtained from metals, and shows the the Arabs used mercury in the treatment of skin diseases and that from 1500-1554 it was given to children in doses of from 2 to 20 grains and that worms had been expelled by these means. The first chapter of the second volume tells how remedies from the animal kingdom were employed by the Egyptian, Greek, and the Roman physicians, and some space is given to a discussion of the value placed by the ancients on precious stones as therapeutic remedies. Familiar medicines, noted nostrums, poisons in history, names and symbols are all made subjects for discussion; in fact, the entire work is a perfect mine of wealth so far as Old World medical lore is concerned.

The Prescribing of Spectacles. By Archibald Stanley Percival, M.A., M.B., B.C., Cantab. Senior Surgeon, Northumberland and Durham Eye Infirmary. New York: William Wood & Co., 1911.

This very excellent work forms a small volume of 159 pages. It is well adapted for the use of students who have some knowledge of mathematics and desire to give the subject careful consideration. The phraseology is clear and direct, the descriptions explicit. Many optical combinations are reduced to simple formulæ. The anomalies of the muscles concerned in the application of glasses, and the properties and use of prisms in correcting these anomalies, are fully considered. A chapter of 38 pages is devoted to optics. The book is sufficiently well illustrated. The volume is worthy of the careful study of all individuals who are engaged in the prescribing of glasses for the correction of errors of refraction.

Die Gicht und ihre diätetische Therapie. Von Prof. Dr. A. Schittenhelm, Erlangen, und Privatdozent Dr. J. Schmid, Breslau. Halle a. S.: Carl Marhold Verlagsbuchhandlung, 1910.

Few scientific investigators have contributed more to our knowledge of the chemistry of purin metabolism than the senior author of this pamphlet on the treatment of gout, and the reader who takes it up with high expectations will not be disappointed. The first twenty-one pages are devoted to a consideration of the chemistry of the purin bodies, the pathology of nuclein metabolism, and the theory of gout. It is unnecessary to state to-day that we as yet know but little which may be considered as definitive in regard to this important problem; but the very careful metabolic studies now being carried on both in Germany and in this country are gradually leading to a considerable body of definite information on the quantitative excretion of the purins and the influence of diet and medicine on this excretion. We know that the process of the formation of uric acid from the nuclear proteids and its destruction in the tissues is in some way less active than in normal people. What causes this interference with the metabolism of a given substance we do not know. Certainly the gouty person has an excess of uric acid in the blood, and this excess is frequently deposited in the tissues. All that we can say of diet is that it should be as nearly purin-free as possible. It will depress many gouty sufferers to learn that the authors consider that alcohol in every form must be absolutely forbidden. The purin-free diet lists furnished in the chapter on treatment are nearly as repellant to the appetite as the lists offered to diabetics. The book will be of assistance to every practitioner who looks beyond his prescription pad in the treatment of chronic diseases.

Behelfsvorrichtungen beim Sanitätsdienst im Felde. By Dr. Westphal, Senior Surgeon Guard-Fusilier Regiment (German Army). Berlin: August Hirschwald, 1910.

This book, No. 29 of the von Coler Library, was originally intended to show the improvised means of assisting the wounded, on the field, during transportation, and in hospital, employed by the Germans during their late campaign against the Hottentots in German East Africa. It was, however, expanded to include consideration of other makeshift appliances which might be found useful to medical officers in campaign. To the American medical officer the book makes interesting reading, not that it gives much information that is new to us, but rather through the quiet amusement which comes from reading of improvised methods and anpliances known and used by us in all our wars, but apparently new discoveries to our Teutonic confrères, who will undoubtedly hereafter regard them as "im Deutschland gemacht." When it comes to improvising an ingenious way of meeting a difficulty probably none excel the American, and illustrations solemnly showing how you clasp hands to make a chain seat, how you immobilize a wounded arm by pinning the sleeve to the chest, and others depicting apparatus of to us inconceivable degrees of crudity and clumsiness rather excite the risibles. But the book can be read by surgeons with much profit, since it clearly indicates the tremendous difficulties of caring for wounded in campaign and destroys undesirable illusions as to the possibility of supply of many medical and surgical conveniences and appliances which, after all, can be quite well done without.

Society Reports

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Annual Meeting, Held January 23, 1911.

The President, Dr. James F. McKernon, in the Chair.

Address of the Retiring President.—Dr. John E. Weeks made this address and said that in turning over the affairs of the office of president of this society to his successor he wished to congratulate them on the excellency of their selection for president for the ensuing year. They had chosen one who would fulfill the duties of the office with justice to all concerned, and who would preside at their meetings with efficiency, dignity and grace. Dr. McKernon brought to the office a ripe experience, a knowledge of the duties and objects of the society, and a degree of wisdom that could not fail to lead them aright. On retiring he wished to thank the members of the Comitia, the members of the Board of Censors, the members of the Committee on Admission, the members of the Committee on New Members, the members of the Committee on Legislation, the members of the Committee on Public Health, the members of the Committee on Audit, the members of the Milk Commission, the other members of the society and the counsel for the society and his associates for their uniform courtesy and hearty co-operation. At the present time the society was fulfilling the objects of its creation in a very creditable manner. It was maintaining a high standard of ethics, giving full attention to the scientific features, and doing a very large service in the suppression of the illegal and the improper practice of medicine. It was also carefully watching and directing legislation as it related to medicine, endeavoring to assist in securing and putting into practice proper health regulations, etc. In studying the proceedings of the society it had come to the knowledge of many of the workers that certain changes in and additions to the by-laws as suggested by his predecessor were needed. He had no doubt that these changes would be made in the near future. It had been thought advisable by some of the members of the society that a permanent central office for the society should be established. This could be done, as suggested by Dr. Carr, by securing a room in the building of the Academy of Medicine and supplying it with a sufficient clerical force. The clerical work of the society, the business of the treasurer and of the secretary could be conducted here, and the archives of the society could be properly filed and stored. As the society increased in numbers and the business of the society increased, such a central office would undoubtedly become necessary. He took pleasure in turning over the gavel to Dr. McKernon.

Inaugural Address of the President-Elect.—Dr. James F. McKernon, after thanking the society for the honor conferred upon him, called their attention to the objects for which the society existed. Its first object was to advance the science of medicine, to disseminate medical knowledge, and to raise the standard of medical education; the second object was to secure the enactment and enforcement of just medical laws, and to guard the interests of every individual member of the society by protecting him from fraud and imposition, and finally to direct public opinion in the proper manner for the welfare of the community. In order that working unity might be preserved it was necessary that the officers elected should exercise all diligence and care in the performance of their duties and that the members of the society should recognize that they had duties to perform other than attending the meetings. They should keep informed as to the work of the Society not only along medical lines but upon all other matters which engaged the attention of the organization. Members should investigate impartially all alleged infringements of so-called ethics before charges were brought to the notice of officers for their deliberation and action. They could not reasonably be expected to donate their time in sifting charges that had as their basis either prejudice or a desire to embarrass them in their executive capacity. Every member should consider it his duty to increase the membership of the Society. There were nearly as many practicing physicians in this county who were outside the Society as were enrolled. The advantages accruing from membership should be emphasized. The advantage of coming into contact with the leading men in their profession was an obvious one and that afforded by the legal protection against blackmail was one which no physician could afford to be without. Few such suits would be brought if it were realized that the moral force of such a society as this stood behind the individual, and that he had at his command the highest legal skill and that his professional brethren would not stand idly by and see him wronged. In arranging for the work of the Society for the coming year they would endeavor to have it appeal not so much to the specialists, as to the every-day needs of the man whose important duty it was to practice general medicine. While it might not be feasible at present to publish the transactions and discussions together with such other items of interest that were of value to all, this course might be advisable in the future; it was to be regretted that such a mass of scientific material should go unrecorded. The monthly folder might be so enlarged as to contain brief abstracts of the papers to be read at future meetings and resignations and transfers might also be included. Dr. McKernon reminded them that both the Society and the public owed a debt of gratitude to the members of the Milk Commission for the admirable work which they had done during the past year, and emphasized the importance of that work of the medical profession which pertained to the education of the public in all matters affecting the health of the community in which they lived. The prestige of this Society and of the medical profession as a whole depended upon the honesty, ability and loyalty of the individuals who composed it, and as such it was their duty to educate the public to a better understanding and a deeper appreciation of their profession.

The Selection of Patients for a Tuberculosis Sanatorium, with Special Reference to the Otisville Sanatorium.—Dr. Charles B. Slade read this paper. The factors to be considered in the selection of patients for a sanatorium he arranged under three headings or sections, as follows: (1) The community or city's point of view. Since the institution was provided at the expense of the community, patients should be chosen along lines calculated to return the greatest possible good to the community. One of the primary objects of a sanatorium was to accomplish a cure or arrest of the disease; the permanency of a cure or arrest depended somewhat upon how well the educational influence of the institution was applied by the patient after he left the sanatorium. One of the most important functions of a sanatorium was the education of its patients upon self-care, and the prevention or control of tuberculosis. It should disseminate knowledge upon these subjects among the people. Therefore, it was most important that the patients selected be of the highest possible standard of intelligence and personal desirability, commensurate with fairness to the city's poor. The Municipal Sanatorium of the Department of Health of New York City, at Otisville, N. Y., was a charity. (2) Those factors relating to the welfare of the sanatorium itself. A sanatorium should not be compared to a hospital; in the former the patient was not so ill but that he could be called upon to perform definite work. The

physical conduct of the Otisville Sanatorium depended upon a considerable volume of actual work by its patients. It was necessary, therefore, while selecting patients for this institution, to maintain a fair average of bodily strength in those admitted. Patients who should be confined to bed from the very day of admission could not be accepted. (3) Those factors relating to the individual patient, who was an applicant for admission. Primarily they tried to admit only those applicants who had pulmonary tuberculosis. Patients with widespread and advanced lesions, unless the general condition was remarkably good, as was sometimes seen with old fibroid involvement, were not admitted. Applicants with the following were apt to be rejected: Temperature up to 100° F. or more every afternoon, unless all other features of the case were favorable; attacks of high temperature (103° F. or more), severe night sweats or any signs of severe mixed infection; habitually rapid pulse (110 or more when at rest); recent, repeated and profuse hemorrhages; marked bodily weakness and emaciation; marked dyspnea on slight exertion; tuberculous laryngitis when severe; tuberculous disease of bones, glands when severe, testicles, intestines, peritoneum or joints; pleurisy with a large amount of effusion; those of over fifty years of age, where the arteries showed marked fibroid changes, and in whom pulmonary tuberculosis was not the chief cause of illness. Patients with any of the following diseases in severe form were apt to be rejected: Nephritis, cardiac disease, nervous disease, diabetes or any other disease which materially impaired the general health; any contagious or communicable disease (not tuberculosis). Those who were apt to be rejected were women who were pregnant five months or more; cases of insanity; chronic alcoholism; those who had repeated attacks of acute alcoholism; those addicted to some drug habit; those with marked neurasthenia; those with a criminal record, a bad moral character, or a markedly undesirable disposition.

Dr. Slade presented a card which he had devised and placed in operation which aided in the selection of patients; it was a reference card for Otisville Sanatorium and tended to avoid delay in decision upon applicants for admission. These cards were distributed to all dispensaries where pulmonary tuberculosis was treated. In about twenty months Dr. Slade examined 1,716 applicants for admission to the Otisville Sanatorium; of this number 488 were rejected for various causes. In examining patients who had been recommended to the sanatorium, the two features which had impressed him as deserving their greatest consideration were, first, the very great number on whom a positive diagnosis of pulmonary tuberculosis had been pronounced without sufficient evidence to justify it and, secondly, the relatively large number of sputum positive cases too far advanced to be admitted under their present arrangements, and who were an active menace to the community. Most of the doubtful cases were rejected. During the three months ending December 1, 1910, the total admissions were 200; of this number the sputum had been constantly negative in 91 cases; of these 91 cases the lesion was described or located by the physician recommending the patient in only 28. In 17 of these 28 negative cases the site and character of the lesion were entirely different from their findings at the sanatorium. In more than 60 per cent. some one was wrong. In some of the cases they could find nothing in the region said to be involved, but thought they could find signs of a lesion in the opposite lung. This might be due to a clerical error. More care than was now generally exercised in fixing a positive diagnosis and recommending sanatoria should be used. It was encouraging to see the public now so aroused that they came to them and to the clinics for examination and diagnosis at the first signs or symptoms which they thought might be due to tuberculosis. This placed upon them a heavy responsibility and a demand for caution before pronouncing a positive diagnosis. It was an unfortunate fact that the primary diagnosis clung to most of these people indefinitely, whether it was right or wrong, with all the limitations of usefulness and happiness that were associated with it; every indisposition or illness they had subsequently, no matter what the cause, was very naturally accepted as an additional evidence of the correctness of the original diagnosis of tuberculosis. He could not emphasize sufficiently the importance of extreme care and deliberation before pronouncing a diagnosis. Dr. Slade next considered the sanatoria as a factor in the segregation of dangerous cases; in his opinion the wisdom of admitting only early cases was open to question. The usefulness of community sanatoria would be enhanced by enlarging their capacity, so as to care for the more advanced cases; this would make them a more important factor in the segregation of actively infectious consumptives. It had been their experience that a large percentage of advanced cases were improved by sanatorium treatment and that none were injured by it. Hundreds of patients who were anxious to go to a sanatorium, but whose disease was too far advanced, who absolutely refused to go to a hospital, were active distributors of infection; they traveled in street cars and moved about among city crowds generally, distributing the disease by droplet infection. They were often worthy people, but who could prevent the spread of droplet infection when these poor afflicted individuals rode, coughed, or sneezed in a crowded street car or subway train? By considerably enlarging their infirmary capacity, the community sanatoria would materially add to their value, as a factor for segregation of a type of the highly infectious consumptive, who was now a menace to the community.

Dr. James Alexander Miller congratulated the Health Department on having established at Otisville a sanatorium managed along the most progressive lines of any in this part of the country, due mainly to the efficient supervision and planning of Dr. Biggs and the able work of Dr. Slade, the reader of the paper, and Dr. McSweeney. He spoke of the change in the past ten years in the character of cases which had come to him as applicants for the various sanatoria—the percentage of advanced cases referred by physicians having become progressively less, so that now his experience coincided with that of Dr. Slade that very many cases applied on the recommendation of physicians in whom no adequate evidence of tuberculosis existed. The reasons for this were mainly—first, the campaign of education of early diagnosis among both the physicians and the laity; second—the lack of appreciation of the true significance of the positive tuberculin tests, especially a cutaneous test, it being positive in probably 80 or 90 per cent. of all adults; and third—the lack of appreciation of the fact that all old healed lesions no longer needing treatment often gave appreciable physical signs during the patient's entire life. He disagreed with Dr. Slade as to the advisability of establishing a large infirmary for advanced cases at Otisville, contending that such an institution should be near the city on account of the difference in expense involved and the nearness to relatives which was more necessary in very sick cases, there being, however, no doubt but that the urgent immediate problem confronting the city was how to secure sufficient institutional accommodations for all advanced cases in order to prevent the spread of the disease. He expressed the opinion that instead of this plan there was another proposed plan for the establishing of an industrial colony for discharged cases in or near Otisville, which seemed to him the more logical step in the development of the usefulness of that institution.

Dr. Linsey R. Williams of New York and Dr. Edward S. McSweeney of Otisville discussed the paper.

Dr. Woods Hutchinson wished to place himself on record as favoring the continuance of the sanatorium care of cases of incipient tuberculosis; these institutions had been helpful in the past, although they might have been in a way hurtful. They were an aid in assuring people that tuberculosis was a disease that often could be cured. As many as 60 to 75 per cent. of the patients with this disease came to them expecting to be cured, an impossible thing in so many instances. He advocated the institution of a campaign to increase the capacity of sanatoria.

Dr. Alfred Meyer said that they should not be carried away by too much enthusiasm. Very few realized the enormous amount of money expended in caring for the tuberculosis cases in the Greater City of New York; tuberculosis patients cost the city a large amount of money, especially those in the advanced stages.

A Morning at Bier's Clinic in Berlin.—Dr. Harry G. Watson told of his experience at the Royal Surgical Clinic in Berlin. The amphitheater was rather small and steep, nothing up to date about it like the amphitheater in the second Medical Clinic at the Charity Hospital, which was a model for all the world to copy. But one should remember that it had been in service for many years. It was much like any other ordinary amphitheater, with plain folding seats, but solid and substantial. Every seat was taken, occupied by medical students of the University, more than one hundred in all, twenty of whom were women. The cases that came to the clinic that morning for diagnosis and treatment were the following: Carcinoma of lip; carcinoma of jaw; fracture of nose; fracture of rib; fracture of femur; cavernous angioma of head in a baby; cellulitis of hand; carcinoma of descending colon; carcinoma of rectum; carcinoma of breast. Each of these cases was carefully examined by two students, the diagnosis made, treatment advised, and the prognosis given. Prof. Bier helped them in giving a differential diagnosis in each case. The medical students in Berlin got a very practical training.

Dr. Willy Meyer said that Germany was slow in building clinics. He had found it very interesting to spend a few hours with Prof. Bier and he would never forget the pleasant hours that he had spent with him and what he had seen behind the screen. He was a most excellent teacher. The students were called down to examine every case in the clinic; after each one had been gone over, there was practically nothing left that textbooks could add to what had been demonstrated. Dr. Meyer said that American students would learn much there, provided they understood the German language. During one morning spent at the clinic Prof. Bier showed the following cases: Ankylosis of the elbow; dislocation of the shoulder; extirpation of the thyroid gland; amputation of cancer of the breast; carcinoma of the stomach. All this was done in one and a half hours. The possibility of doing so much work was due to the fact that the patients were rolled into the amphitheater after being prepared for operation and anesthetized; after the operation they were immediately rolled to another room where the final dressings were applied. Dr. Meyer believed that Prof. Bier belonged to the finest type of men of the world, straightforward in all that he did, and that every word spoken by him was the truth.

NEW YORK ACADEMY OF MEDICINE

Stated Meeting, Held January 19, 1911.

The Vice-President, Dr. Glentworth R. Butler, in the Chair.

This meeting was under the auspices of the Section on Neurology and Psychiatry and the subject under discussion was "Criminality."

Some Social Causes of Criminality.—O. F. Lewis, Genaral Secretary of the Prison Association, mentioned as conditions predisposing to criminality poverty, child labor, night messenger service, children playing on congested city streets, industrial accidents that disrupted families, throwing sons and daughters on their own resources, and small wages and overwork that frequently hurled frail women into the street. He discussed more particularly certain conditions prevailing in the administration of many of our correctional institutions which result, after the discharge of the prisoner, in his becoming in turn a cause of further crime. He called attention to the frequent absence of adequate physical and mental examination and treatment of prisoners; to the present state of the parole system; to the previous careers of delinquency of many inmates of reformatories and State prisons; to the present methods of dealing with tramps, vagrants, inebriates and young misdemeanants. Elmira Reformatory, in many ways the standard reformatory, not only of the United States but of the world, based its methods upon the assumption that prisoners of normal or average mentality would be benefited by their stay in the institution. Yet it has been recently found that at least 39 per cent. of the inmates were mentally defective, and 70 per cent. below the normal physical standard. This has led to the recommendation of the introduction into the present legislature of a bill permitting the reformatory to transfer the imbeciles now at Elmira Reformatory to a custodial asylum. There was a practical certainty of similar conditions as to feeble-mindedness in our penitentiaries, jails and state prisons. Mr. Lewis presented statistics from the Elmira Reformatory showing that a large percentage of these mental defectives had a previous record of delinquency and that after their release from the institution an equally large percentage again became delinquents. He referred to the presence of tuberculosis in prisons and the advantage of isolating the victims of this disease. He recommended the following developments as essential in the institutional and non-institutional treatment of offenders. (1) The rational extension of the suspended sentence with the accompanying probation system. (2) Adequate physical and mental examination of all persons committed to correctional institutions, such examinations to take place not only at their entrance to such institutions, but as often as necessary during their term of imprisonment. (3) The adequate treatment of the mentally defective and the diseased in correctional institutions, not only by proper medical authorities, but also through the provision of separate institutions when necessary, such as custodial asylums for the criminal feebleminded, and tuberculous hospitals or wards for the tuberculous. (4) The development of an adequate and systematic parole system, necessary elements in which shall be a competent parole board: adequate study by the parole board of inmates seeking parole; a period of parole supervision covering if necessary a period of time equivalent to the maximum sentence for the crime committed; an adequate staff of parole officers: the development of employment agencies and relief agencies for released and discharged prisoners; the return of delinquent paroled men (or women) to prison for violation of parole, unless sufficient extenuating circumstances exist. (5) The further classification of offenders, so as to separate young misdemeanants from older misdemeanants through the establishment of a state reformatory for misdemeanants; the separation of habitual tramps and vagrants from other offenders through the establishment of one or more compulsory labor colonies for habitual tramps and vagrants; the separation and proper treatment of inebriates and alcoholics through the establishment of one or more hospitals and colonies for this class, and the establishment of boards of inebriety with the accompanying probation system as advocated by the State Charities Aid Association

and made permissive to New York City through legislation at the sesion of 1910. (6) The extension of the study of defective delinquents within and without institutions through the work of a committee such as the Committee on Defective Delinquents just appointed by the Prison Association of New York.

The Criminal from a Medical Point of View.—Dr. Robert B. Lamb, Superintendent of the Matteawan State Hospital for the Criminal Insane, stated that as long ago as the time of Socrates certain physical abnormalities had been ascribed to the criminal. In 1820 Grohman had called attention to the prevalence of certain physical abnormalities in criminals that were of common knowledge to-day. He expressed himself as "especially impressed in criminals by signs of defective development, by the prominent ears, the shape of the cranium, the projecting cheek bones, the large lower jaw, the deeply placed eyes and the shifty animal-like gaze." The Italian school had written so convincingly that their readers were led to believe that those of the criminal class were easily and surely identified by certain physical characteristics alone, but nowadays one realized that these elementary comparisons were not altogether fair. There were well-defined limitations to the findings of the Italian students. While the cranial measurements of criminals presented certain abnormalities, these abnormalities were usually reflected in the extreme and not in the average. The general average of the criminal heads was much the same as for ordinary people's heads, but among criminal heads there were a greater number of small heads and a greater number of large heads The possessors of these small heads had more frequently committed crimes against property, while the possessors of the large heads had more often committed crimes against persons. These conclusions had to be further modified in accordance with racial characteristics and locations. Receding foreheads were now considered significant only when the other dimensions of the cranium were taken into account and found wanting. Lombroso found that the orbital capacity was larger in the criminal than in the ordinary man. Lack of symmetry was so common that the real question seemed to be how much asymmetry was necessary to bring a head within the so-called criminal type. The same degenerative abnormalities appeared with much greater frequency in male than in female criminals. With so many variations from the normal present externally it would be strange if no internal variations were noted. Broca had noted that the presence of numerous confluent fissures indicated a defective degree of development. In nearly 50 per cent. of these cases examined by Lombroso and Flesch there were signs of a well-defined meningitis. There were reasons for believing that in certain cases there was defective formation of the intimate structure of the brain which defied the powers of the keenest observers. Dr. Lamb thought that the internal stigmata were fully as common, if not more so, than the external. The lack of facial beauty among criminals had been frequently referred to. The International Prison Congress held in Paris recommended physicians to go to the prisons to study psychiatry and this recommendation was sound. As a result of such a training the Superintendent of the Elmira Reformatory weeded from his population seventy-four men, too much deranged to comply with the school requirements of the Reformatory, whose presence was demoralizing to the entire institution. The most apparent mental defect in the criminal was simply a decided weakness, eminently disproportionate if comparison was made with the great body of citizens. The reasoning and judgment of the adult prisoner was, as a rule, inferior to that of the youth of the free world. The criminal had little insight into his own condition and was vain and egotistical, much overrating his own powers. He would take great risks for small gain and failed to profit by his first lesson when imprisoned. The reports of the Elmira Reformatory showed that 45 per cent. of its inmates had been in previous contact with some branch of the law before they had received the reformatory sentence. As time went on these habitual offenders had few friends in the world at large and regarded their discharge from prison in the light of a vacation. They felt more at home in prison and were almost sure to be returned in the course of a comparatively short period. There was on the statute books a law that provided for the life care of chronic offenders, but up to the present time, two years after its enactment, only two sentences had been pronounced under it, while 103 prisoners were admitted, known to be eligible for this sentence. Absence of moral sense was sometimes inherent in the individual and sometimes the result of disease or vice. When moral sense was wanting it meant distinct antisocial tendencies. Such individuals were a constant source of danger to the community. There was a class in which there was total failure of development so far as this sense was concerned. In some cases the physician might postpone or abort inflammatory processes provided the patient was seen early enough. The treatment should be continued over a long period of time until the skilled observer deemed it safe to try his pupil in a free world. Even then no one could be certain of the result. That class of insane criminals who committed crimes because of active disturbance of the mental processes were rarely referred to by criminologists. They did not in truth belong to the criminal insane; they had reached a superior standard of development and had broken down after its attainment. Legal provision was urgently demanded for that class of criminals who were criminals from failure to develop. It was necessary that provision should be made for them in the interests of the State as well as of the individuals themselves and their families.

Legal Aspects and Problems of Preventive Measures.—Hon. Julius M. Mayer spoke of the desirability of a physical examination of the child brought to the Juvenile Court. He read letters on this subject received from Judge Merritt W. Pinckney of the Juvenile Court of Chicago and from Dr. James A. Britton, attending physician at the Juvenile Court. Judge Pinckney stated that no examination of the genitalia was made without the consent of the parents. He had felt that he had no right to make such examinations without the consent of the parents. After the hearing of the case, if it became necessary to send such children to a detention home, it had been the policy of the court to have such examinations made before allowing the children to mingle with other children in the institutions. Dr. Britton had stated that before taking up the examination work in the Juvenile Court it had been discussed by a great many people interested in the welfare of children and it was decided, theoretically, at least, that it would be of great advantage to the child and also to all the people who were attempting to handle the children's cases. They had been examining all children who came into the Juvenile Court since September, 1907, and it had been their experience that the examination proved very desirable and, in fact, an essential thing in the proper handling of children. Theoretically all of the children who came into the court had had this examination in the regular public schools and when they appeared in court they could bring this record with them. If this were really done a large part of the examination of children now done in the court could be eliminated. It was too bad for a child to drop out of school, get into trouble, and, after reaching the Juvenile Court, have it found out that he could not hear or see or that he had some mental defect that made it impossible for him to be treated like other children and until a careful routine school examination was made such things were bound to happen

every day. Such examinations were necessary in order to guard against contagion and venereal disease was classed as a contagious disease. It was almost criminal to bring little girls together in a home without first noting whether there was such infection. All girls brought into the Detention Home were given a microscopical examination of the vaginal secretion. The boys were stripped and given a more or less thorough examination. The examination of the girls was less complete, but if there was indication of heart or lung trouble the chest was bared for examination. The girls that were brought into the court and taken away the same day without being kept in the Detention Home had a vaginal examination made only in special cases when it was the wish of the parents or guardians.

The Mentally Defective Delinquent and the Law.—Ernest K. Coulter, Clerk of the Children's Court, New York County, read this paper. He said that stirring men to recognition of the most fundamental of the child's rights had been a slow process. It had even been the story of property rights above human rights. A half century ago they were still hanging children. It was only within the last decade that they had ceased arraigning child victims of bad environment in company with the city's thugs. The establishment of children's courts was one of the signs of an awakening public conscience. One of the lessons these courts taught was that the municipality was responsible for the environment that brought thousands of its children each year in conflict with the law. The glaring sin of the State against its children to be dealt with was that which thrust delinquents of tender years who were mentally irresponsible into ordinary reform institutions. These children could be classed as neither imbecile nor insane, but were exceptional children, the victims of environment or congenital causes, which irresistibly predisposed them to crime. The defective included not only those whose minds were stupid and who were at the mercy of the lowest instincts, but also some abnormally bright and unbalanced children who, unchecked, developed into criminal geniuses before they were out of their teens. After a near-view of about 80,000 cases of children under the age of sixteen who had been brought before a single tribunal with which he had been connected, he positively asserted that the vast majority who were charged with getting into conflict with the law were normal from the standpoint of their surroundings. The Superintendent of the Bedford Reformatory for Women reported that an examination of 35 inmates showed that 13 were subnormal. This superintendent declared that 33 per cent. of the inmates were mentally defective. They had heard that 39 per cent. of the inmates of the Elmira Reformatory were mentally defective, and 70 per cent. were physically defective. If, while these defectives were still children, the causes of the abnormal condition which predisposed them to prey on society could have been removed, they could have been saved to useful citizenship. In such cases the time for relief was in youth. The Children's Court of New York County handled about 10,000 cases each year and practically one-half of them were taken into custody because of alleged trivial offenses, growing out of the child's normal instinct to play. With a conservative estimate of 2 per cent. of mental defectives there were 200 of these unfortunates coming into this court each year, not to mention the three other children's courts in Greater New York. There was not one institution where children of the mentally defective type could be sent on legal commitment. To show what happened in these cases he reported the case of a youngster of fourteen, apparently a junior Chesterfield, who was arraigned in Children's Court several years ago charged with having stolen a large amount of money from a department store by a series of clever forgeries. His attractive face, polite speech, and immaculate dress marked him in strange contrast with the motley crowd that usually faced the judge. Even the detective feared that he had made a mistake and was inclined to ask that the charge be dismissed. After a long talk with the judge the boy finally confessed that he had forged the checks. This boy had come out of the West, where he had founded and edited a newspaper when eleven years of age His father was a poor printer. With no other collateral than his unmitigated nerve he had traveled through the country and stopped at the best hotels. He was living at the Waldorf-Astoria when arrested. He had even induced Russell Sage to invest in one of his Western schemes, so great were his persuasive powers. This young marvel was committed to the reformatory and the officers were urged to keep the boy in the background. As a guest among five hundred others at a Washington Birthday celebration at this institution the writer had seen this same boy, occupying the center of the stage in powdered queue and cocked hat taking the part of George Washington himself. In a few months he talked himself out of the institution and into a Washington bank, where he soon learned sufficient to enable him to disappear with a considerable sum of the bank's money. He was arrested later in a Western State and sent to a reformatory. Upon his release he obtained employment as a traveling salesman. In a Kansas City hotel between midnight and dawn he turned on the gas and was found dead. He left this note: "Worry, unhappiness, undeserved condemnation, and hatred of wrong-doing are the cause." This note showed that he realized his own mental irresponsibility. Had he received proper treatment on the first indication of his criminal tendencies he might have been saved to a brilliant and honorable career. Several other cases of exceptional children were cited. Some boys of this class showed morbid cravings for sympathy and marvelous inventive genius. Some exceptional children, usually girls, had attempted suicide because of fancied grievances. These children might be placed in two great classes, those with acquired and those with hereditary mental disturbances predisposing them to crime. The number of children in the public schools of New York whose mental defectiveness was recognized was 7,000 or one per cent. of the total attendance. At present there was no municipal provision for sifting out the defectives in the custody of the authorities. There were no special institutions to which such cases might be committed. The same condition existed throughout the country. There was needed a general awakening to the fact that a number of exceptional children were arraigned in Children's Court each year and although they were irresponsible for their acts they were being thrust into ordinary reform institutions. Here there was nothing for them but acute suffering and habitual criminality. The causes of the mental condition of a large number of them could be removed and they could be saved to useful citizenship. In its gradual abandonment of antiquated and barbarous methods of treating child offenders the State must recognize that the defective child required special treatment. They could ill afford to hesitate longer in taking this step in line with humanitarian progress.

Rev. Dr. Charles H. Parkhurst said that he was glad that the sentiment expressed promised to become so widespread, but he hoped that they would discriminate between two classes of children in their endeavor to give every child a fair chance. He asked if they believed that a child who was normal both mentally and physically would become a lawbreaker. Dr. Parkhurst confined his remarks to the question as to how far personal responsibility might be affected by physical or mental abnormality.

Judge Mayer said that if a child's abnormality was purely a physical one he then would be responsible. The ab-

normality must be a mental one, the child must be legally insane, if he wished to escape legal responsibility.

Judge Duell believed that the proper time to discover whether or not a child was defective was when he was in school. If more attention was paid to the matter at this time they would not have such a number of children in Court charged with some infraction of the law.

Judge Hoyt said that he was in accord with the sentiments already expressed.

Mr. Thompson, Superintendent of the Society for the Prevention of Cruelty to Children, said that the society which he represented looked for the cause of the delinquency; they endeavored to deal with normal children in the schools and employed preventive measures whenever possible. This society looked after 50,000 children; 40,000 of them were normal children and never reached the Children's Court. The mentally or physically defective child could not be properly cared for in this city because there was no institution for his care. By correcting conditions at home many children were kept out of Court. Thirty per cent. of the cases seen last year had need of an institution such as they had met to discuss. The medical and legal profession of the city should endeavor to bring about the organization of such an institution. The Society for the Prevention of Cruelty to Children would aid so far as it could.

Dr. Max G. Schlapp quoted statistics that showed the increase in criminality among children because of the inadequate methods that had been used. He stated that statistics from one reformatory showed that 9.1 per cent. of its inmates were defective. A year later the same inmates, 200 in number, were examined by a trained man who found that 73 of the number were normal and the balance defective. This showed that the examination of children in these institutions should not be left to laymen but should be conducted by trained men. Probably 50 per cent. of the criminals in the community were taken from the class of infants under discussion and the question was how they could reduce this class of individuals. Instead of allowing feeble-minded individuals to roam about, the State should care for them before they reached that period of life when they began to commit criminal acts. This could be done if the means were forthcoming. Dr. Schlapp advocated the establishment of some central station where these children could be examined. He thought the law should make it compulsory for the physician to register feeble-minded persons; such reports should be kept secret. The central station would be in a position to help the general practitioner in determining what should be done for a child.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

State Board of Medical Examiners of Tennessee.

Nashville, Knoxville, and Memphis, May 3-4, 1910.

ANATOMY.

1. What organs are found in abdominal cavity?
2. Describe the abdominal cavity. Muscles and bones that form the same.
3. Name the muscles of the gluteal region, origin and insertion of same.
4. Describe the femur and the bones with which it articulates.
5. What organs are found in the thoracic cavity?
6. Name the facial muscles.
7. Trace the femoral artery. Name the important branches given off by same.
8. Name ten cranial nerves.

PHYSIOLOGY.

1. Name the principal chemical elements found in the human body.
2. Mention the enzymes found in the gastrointestinal canal and the action of each.
3. What is the function of the iron of the red blood cells?
4. Name the three cardiac ganglia.
5. What causes the blood to flow in the veins?
6. What are the functions of the suprarenal glands?
7. Mention the principal automatic and reflex centers found in the medulla.
8. What would be the effect of a lesion of the lower half of the pons Varolii?
9. If the left occipital lobe of the brain were destroyed, what would be the effect on the sense of sight?

CHEMISTRY.

1. Give the chemical formula for carbolic acid. How is it obtained and what are its properties and uses?
2. Give chemical formula for ethyl chloride. How prepared and its uses?
3. Explain how water and its contained impurities may become purified by running in a shallow stream over a precipice.
4. Give chemical test for free hydrochloric acid in stomach contents.
5. What is the range of the specific gravity of normal urine? State what diseased conditions produce (*a*) an abnormally high specific gravity of the urine, (*b*) a low specific gravity of the urine?
6. When testing for glycosuria with Fehling's solution, how do you determine whether the reaction is that of sugar or some other reducing agent?
7. How do you detect the presence of bile in a specimen of urine? Name the principal bile pigments.
8. What is the urinometer? State its importance as an aid to diagnosis.

MATERIA MEDICA.

1. What is magnesium sulphate? Give its use in the practice of medicine.
2. From what source is heroin, and what is the dose?
3. Give the source of atropine and dose.
4. What is hydrastis? Give the dose and describe the pathological lesion for which you would use it.
5. What is the source of sulphocarbolate of zinc?
6. What preparation of iron is used in erysipelas? The dose? How often repeated and mode of administration?
7. For what pathological lesion would you use iodine?
8. What is the dose of calcium sulphide? Potassium chlorate? Potassium bromide?

PATHOLOGY.

1. Describe the pathology of the liver, lungs, and blood in pernicious intermittent fever.
2. Give the pathology of the gastric intestinal tract in acute alcoholism.
3. Describe the pathologic changes in the blood in pyemia.
4. Describe the pathology of the blood in septicemia.
5. Describe the pathology of scurvy.
6. Describe the pathology of gonorrheal arthritis.
7. Describe the pathology of the joints when the seat of chronic inflammatory rheumatism.
8. Describe the morbid changes in the valves in mitral stenosis.

PRACTICE.

1. Name the diseases which you expect to encounter in your practice in Tennessee. Name your methods of making diagnosis of diseases.
2. Name the specific causes of lobar pneumonia. What would auscultation and percussion reveal in the first stage of congestion of the lung? Give a treatment for lobar pneumonia.
3. What is endocarditis? Name the causes which produce it. Give treatment for it.
4. Name the specific cause of typhoid fever. How does it gain entrance to the body? Differentiate typhoid fever from remittent fever. Give a general treatment for typhoid fever.
5. What is cerebrospinal meningitis? Name its specific cause. Differentiate between epidemic crebrospinal meningitis and tuberculous meningitis. Give the clinical features of each.
6. Describe the eruption of smallpox. Of chickenpox and of measles. What is the period of incubation of each?
7. Give the differential diagnosis between tonsillar diphtheria and follicular tonsillitis. Name the treatment for diphtheria.

8. Name the chronic diseases of the liver. What are the symptoms of obstruction of the common bile duct? What are the symptoms and clinical manifestations of biliary calculi? Name a treatment for biliary calculi.

OBSTETRICS.

1. State in detail your management of a normal labor from its inception to its close.
2. Give the differential diagnosis between a primiparous and multiparous woman. How would you calculate the date of confinement?
3. Mention the signs of pregnancy at three months and at six months, naming them in order of their importance.
4. What is your opinion of the Cesarean section? At what time and under what conditions would you advise it?
5. After the period of viability, how would you diagnose a dead fetus, and, if dead, what would you do, and how would you do it?
6. Given a case of placenta prævia approximating full term, what would you do? Give advantages and disadvantages of various procedures as regards safety of both mother and child.
7. Mention the uterine displacements that are liable to influence (*b*) conception, (*c*) pregnancy, and (*d*) labor, and state the reasons for such influence.
8. Give a differential diagnosis between ovaritis and ovaralgia.

SURGERY.

1. State the constitutional effects and give the treatment of burns.
2. What general principles govern the diagnosis of a tumor?
3. Describe a method of differentiating between (*a*) the urethra, (*b*) the bladder, and (*c*) the kidneys as the source of pus in the urine.
4. State the most common seat of fracture of the clavicle and describe a method of treatment.
5. Describe the steps in the treatment of a scalp wound.
6. Make a differential diagnosis of coma from (*a*) injury, (*b*) apoplexy, (*c*) uremia, (*d*) opium poisoning, and (*e*) alcoholic intoxication.
7. What are the symptoms and treatment of a sprained ankle?
8. What arteries need ligating in amputation of the middle third of the leg? Describe your method of ligating.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

STATE BOARD OF MEDICAL EXAMINERS OF TENNESSEE.

Nashville, Knoxville, and Memphis, May 3-4, 1910.

ANATOMY.

1. *The organs found in the abdominal cavity* are: Stomach, small intestine, large intestine, liver, pancreas, spleen, suprarenal bodies, kidneys, ureters, bladder, part of urethra; prostate, seminal vesicles, vasa deferentia, and spermatic cords, in male; or uterus, Fallopian tubes, and ovaries, in female; receptaculum chyli.
2. See Cunningham's "Anatomy" (1909), page 1043; or Gray's "Anatomy" (1908), page 1241.
3. *The muscles of the gluteal region* are: Gluteus maximus, gluteus medius, gluteus minimus, pyriformis, obturator internus, gemellus superior, gemellus inferior, quadratus femoris, and obturator externus.

For origins and insertions see Cunningham's "Anatomy" (1909), pages 364, etc.; or Gray's "Anatomy" (1908), pages 525, etc.

4. See Cunningham's "Anatomy" (1909), page 223; or Gray's "Anatomy" (1908), page 223.
5. *The organs found in the thoracic cavity* are: Heart and pericardium, lungs and pleuræ, thymus (or its remains), trachea, esophagus, thoracic duct.
6. See Cunningham's "Anatomy" (1909), page 397; or Gray's "Anatomy" (1908), page 368.
7. See Cunningham's "Anatomy" (1909), page 858; or Gray's "Anatomy" (1908), pages 698 and 704.
8. *The first ten cranial nerves* are: (1) Olfactory, (2) Optic, (3) Motor oculi, (4) Trochlear or pathetic, (5) Trifacial, (6) Abducens, (7) Facial, (8), Auditory, (9) Glossopharyngeal, (10) Pneumogastric or Vagus.

PHYSIOLOGY.

1. *The principal chemical elements found in the human body* are: Carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus, fluorine, chlorine, iodine, sodium, potassium, lithium, calcium, magnesium, iron, and silicon.

2.

ENZYMES.	ORIGIN.	ACTION ON FOOD MATERIALS.
Ptyalin.	Saliva.	Changes starches into dextrin and sugar.
Pepsin.	Gastric Juice.	Changes proteids into proteoses and peptones in an acid medium.
Trypsin.	Pancreatic Juice.	Changes proteids into proteoses and peptones, and afterward decomposes them into leucin and tyrosin; in an alkaline medium.
Amylopsin.	Pancreatic Juice.	Converts starches into maltose.
Steapsin.	Pancreatic Juice.	Emulsifies and saponifies fats.
Invertin.	Intestinal Juice.	Converts maltose into glucose.

3. The iron holds the oxygen in the red-blood corpuscles.
4. *The three cardiac ganglia* are: Remak's, Bidder's, and von Bezold's.
5. *The blood flow in the veins is due to:* The action of the heart, aspiration of the thorax, contraction of muscles, and, slightly, to the valves in the veins.
6. *The function of the suprarenal bodies* is not definitely settled; they produce an internal secretion which is probably necessary to life, which is also said to increase the blood pressure by a vasomotor action on the arterioles; some tonic action on the cardiac muscle is also attributed to them; and it is supposed that they are able to destroy or remove some toxic substances.
7. The principal centers of organic function situated in the medulla are: (1)Center for mastication; (2) for secretion of saliva; (3) for sucking; (4) for deglutition; (5) for vomiting; (6) for voice; (7) center for expression; (8) cardiac centers; (9) respiratory centers; (10) vasomotor centers.
8. *A lesion in the lower part of the Pons Varolii* will cause paralysis of the face on the same side, and paralysis of arm and leg on the opposite side.
9. *If the left occipital lobe of the brain is destroyed* there will be blindness of the left half of each retina; the right half of the field of vision of each eye will, consequently, be lost.

CHEMISTRY.

1. The chemical formula for carbolic acid is C_6H_5OH. It is obtained by heating phenyl iodide and potassium hydroxide at a high temperature:

$$C_6H_5I + KHO = KI + C_6H_5OH.$$

It is a crystalline solid with characteristic odor and acrid, burning taste, neutral in reaction, and very soluble in alcohol and ether. It is used as an antiseptic and in the manufacture of medicinal compounds, dyes, and explosives; also as a local anesthetic, for pruritus, and sometimes internally in nervous vomiting.

2. The chemical formula for ethyl chloride is C_2H_5Cl. It is prepared by the action of phosphorous trichloride on ethyl hydroxide (alcohol):

$$3C_2H_5OH + PCl_3 = H\text{-}PO_3 + 3C_2H_5Cl.$$

It is used as an anesthetic, both local and general.

3. The various processes which aid in the purification of water running in a shallow stream over a precipice, are: (1) Subsidence; (2) Oxidation; (3) Dilution; (4) Bacterial action; (5) Vegetation; (6) Agitation, and (7) Sedimentation.

4. There are three or four chemical tests for free HCl in gastric contents; the best is probably the Dimethylamido-azobenzol test. The reagent is used in 0.5 per cent. alcoholic solution, of which one or two drops are added to a like amount of the filtered gastric juice. If free HCl is present, the yellow solution turns red.

5. The specific gravity of normal urine varies from about 1015 to about 1025. An *abnormally high* specific gravity may be found in: Diabetes mellitus, fevers, and chronic parenchymatous nephritis.

Low specific gravity of the urine, may indicate: Diabetes, insipidus, chronic interstitial nephritis, contracted kidney, albuminuria, hysteria, or some nervous disorders, or the ingestion of an abnormal amount of fluids.

6. By using a further test, such as the *fermentation test:* Three Smith's fermentation tubes are used, each containing a little compressed yeast, one filled with the liquid to be tested, the second with pure water, and the third with a dilute solution of glucose, and the three are put

in a warm place over night. If gas collects in the first and third tubes, but not in the second, the liquid contains sugar; if gas collects in the third only it does not; under any other circumstances the yeast is at fault.

7. Test for *bile:* Put 3 c.c. HNO_3 in a test tube, add a piece of wood, and heat until the acid is yellow; cool. When cold, float some of the urine to be tested upon the surface of the acid. A green band is formed at the junction of the liquids, which gradually rises, and is succeeded from below by blue, reddish-violet, and yellow.

The principal bile pigments are: Bilirubin, biliverdin.

8. A *urinometer* is a form of hydrometer used for determining the specific gravity of the urine.

It consists of a cylinder and a spindle.

The graduation on a urinometer is so constructed that the spindle sinks to the zero point when it is immersed in water at a given temperature. The denser the fluid into which the spindle is immersed, the higher it rises. The ordinary urinometer is graduated from 0 or 1,000 to 60 or 1,060.

Its value as an aid to diagnosis is shown in Question 5.

MATERIA MEDICA.

1. *Magnesium sulphate,* $MgSO_4$, Epsom salt. It is a saline cathartic, and is used also in dropsy, inflammatory conditions, constipation, portal obstruction, increased blood pressure in the brain; locally it has been used as an application in erysipelas or orchitis.

2. *Heroin* is a derivative of morphine. Its dose is gr. 1/24 to 1/6.

3. *Atropine* is the alkaloid of belladonna. Its dose is gr. 1/160.

4. *Hydrastis* is the dried rhizome and roots of Hydrastis canadensis, or golden seal. Its dose is gr. xxx. It is used externally for inflammations (not acute) of mucous membranes; and internally for intestinal catarrh and indigestion, and hemorrhages.

5. Sulphocarbolate of zinc, better called zinc phenolsulphonate, is formed by adding sulphuric acid to phenol, and then treating with zinc oxide.

6. The tincture of the chloride of iron is used in erysipelas. It is given in doses of ♏ xl every four hours; it is also used as a local application.

7. *Iodine is used:* As a counterirritant for chronic inflammation of joints, enlarged glands, chilblains, periostitis, and enlarged glands.

8. *Calcium sulphide,* dose gr. 1/10 to ½; *potassium chlorate,* dose gr. iv; *potassium bromide,* dose gr. xv.

PATHOLOGY.

1. See French's "Practice of Medicine" (1910), page 239; or Osler's "Practice of Medicine" (1909), page 15. The lungs may show hemorrhagic areas, the capillaries may be pigmented or congested.

2. See French's "Practice of Medicine" (1910), pages 747 and 751; or Osler's "Practice of Medicine" (1909), pages 457 and 460.

3 and 4. See French's "Practice of Medicine" (1910), pages 210 and 212; or Osler's "Practice of Medicine" (1909), pages 215 and 216.

5. See French's "Practice of Medicine" (1910), page 542; or Osler's "Practice of Medicine" (1909), page 751.

6. See French's "Practice of Medicine" (1910), page 215; or Osler's "Practice of Medicine" (1909), page 283.

7. See French's "Practice of Medicine" (1910), page 951; or Osler's "Practice of Medicine" (1909), page 394.

8. See French's "Practice of Medicine" (1910), page 593; or Osler's "Practice of Medicine" (1909), page 808.

PRACTICE.

1. See Table of Contents of French's or Osler's "Practice of Medicine"; if you are a specialist mention the diseases comprised in your specialty.

Method of making diagnosis of disease: Inspection, palpation, mensuration, percussion, auscultation, weighing, taking blood pressure, counting blood corpuscles, estimating hemoglobin, microscopical examination of blood smears, urinary examination (both chemical and bacteriological), examination of smears of discharges (microscopical and bacteriological), puncture, examination of gastric contents after test meals, by the use of sounds, bougies, various "scopes," and the *x*-rays.

2. See French's "Practice of Medicine" (1910), pages 151, 158, and 174; or Osler's "Practice of Medicine" (1909), pages 164, 176, and 189.

3. See French's "Practice of Medicine" (1910), pages 576, 577, and 582; or Osler's "Practice of Medicine" (1909), pages 785 and 791.

4. See French's "Practice of Medicine" (1910), pages 65, 67, 103, and 109; or Osler's "Practice of Medicine" (1909), pages 57, 61, 95, and 99.

The following table is taken from an elaborate one by Thayer:

TYPHOID FEVER.	MALARIAL FEVER (REMITTENT)
Blood shows no leucocytes; eosinophiles diminished or absent; serum causes agglomeration of typhoid bacilli; malarial parasites and pigment absent.	Blood shows no leucocytosis; eosinophiles not notably diminished; serum does not cause agglomeration of typhoid bacilli; malarial parasites and pigmented leucocytes present.
Fever uninfluenced by quinine.	Fever disappears under quinine.
Usually epidemic; prevailing commonly in cities.	Is an endemic disease occurring particularly in rural districts; rarely epidemic.
Anemia absent, excepting in later stages.	Anemia more or less marked early in the course.
Characteristic roseola.	No characteristic exanthem; urticaria not uncommon.
Has a fairly characteristic course.	No distinct course.
Urine high-colored; bile absent; Ehrlich's diazo-reaction present during the height of the process.	Urine high-colored; may show a trace of bile; Ehrlich's diazo-reaction rarely present.
Onset gradual and progressive.	Onset generally intermittent.
The temperature does not reach 40° C. (104° F.) before the third or fourth day.	The temperature may arrive at 40° C. (104° F.) within twenty-four hours.
The apathetic expression of the face, the dryness of the tongue, and sordes upon the teeth are well marked and progressive.	These symptoms are not very marked.
Herpes rare.	Herpes common.

5. See French's "Practice of Medicine" (1910), pages 139, 146, and 147; or Osler's "Practice of Medicine" (1909), pages 157 and 301.

Wheeler and Jack give the following table:

CEREBROSPINAL MENINGITIS.	TUBERCULOUS MENINGITIS.
Age.—Any age.	Young children and young adults.
Cause.—Injury or local causes, fevers, etc.	No local cause, but symptoms of tubercle elsewhere.
Course.—Short.	Longer than simple, especially the prodromal stage.
Convulsions.—May be present.	*Common,* even during the compression stage, often precede death.
Abdomen.—Nothing marked.	Markedly retracted.
Pathology.—1. That of simple or suppurative inflammation.	That which is associated with the presence of tubercle, and formation of peculiar greenish pus.
2. Attacks convexity of brain.	2. Attacks the base of brain.
3. Ventricles not distended.	3. Ventricles are distended, and may cause hydrocephalus.
Prognosis.—Almost hope-	Depends on cause and extent.

6. *Smallpox:* The eruption usually appears first on the forehead and wrists, and on the third or fourth day; it is first macular, then papular, then vesicular, and finally pustular; it does not appear in successive crops; the spots are multilocular, and do not collapse on being punctured; the papule is hard and shotty, and does not disappear on stretching the skin. Period of incubation is from eight to fourteen days. *Measles:* Period of incubation, ten to twelve days. Stage of invasion, four days. Character of eruption, small, dark red papules with crescentic borders, beginning on face and rapidly spreading over the entire body; desquamation is branny. The eruption is dark, less uniform, more shotty; Koplik's spots are present. *Chickenpox:* The eruption usually appears first on the trunk, is evident on the first day, comes in successive crops, is not shotty, and disappears on stretching the skin; the spots

are unilocular, and collapse on being punctured. The period of incubation is from four to fourteen days.

7. In *diphtheria* the onset is more gradual; the temperature rises to about 101° F.; the tonsils are not much enlarged; there is an exudate of a thick, grayish membrane which is very adherent, is removed only with difficulty, and leaves a bleeding surface; this membrane soon reforms and may be found on the fauces and pharynx as well as on the tonsils; in the exudate the Klebs-Loeffler bacilli may be found. In *follicular tonsillitis* the onset is more sudden; the temperature may be a little higher than that of diphtheria; there is no membrane, but the tonsils are red and swollen, and in the crypts are seen white, cheesy spots or plugs, which consist of broken-down epithelium, and are easily brushed away; Klebs-Loeffler bacilli are never found.

The treatment for diphtheria is diphtheria antitoxin.

8. *Chronic diseases of the liver:* Chronic hyperemia, chronic interstitial hepatitis (cirrhosis), echinococcus cyst, chronic perihepatitis, gallstones, amyloid liver, chronic atrophy, fatty liver, syphilis of liver.

See French's "Practice of Medicine" (1910), pages 872 and 873; or Osler's "Practice of Medicine" (1909), pages 547, 550, 552, and 555.

OBSTETRICS.

1. See Williams' "Obstetrics" (1909), pages 303, etc., and 298; or Hirst's "Obstetrics" (1909), pages 312, etc.

PRIMIPARA.	MULTIPARA.
The fourchet is present.	The fourchet is missing.
The perineum is tense and deep.	The perineum is relaxed and probably torn.
The labia are in apposition.	The vulva is frequently patulous.
The vagina possesses tonicity, and is rough and rugous, with a granular feel.	The vagina is relaxed and smooth.
The cervix is long, soft, and conical; the os is undilated.	The cervix is large, cylindrical, short, not so soft, and probably lacerated; the os is patulous.
The abdomen is full, rounded, tense, and resisting to the touch.	The abdominal walls are relaxed and non-resisting to the touch; the skin is loose and wrinkled.
Dark, purplish-red striæ appear late in pregnancy.	The striæ may be both white and livid, the former being present from the beginning of pregnancy.
The breasts are full, firm, and sensitive to pressure.	The breasts are flabby, pendulous, and non-sensitive to pressure.
The nipples are usually small and undeveloped or even inverted.	The nipples are large and well developed.
There are no striæ upon the breast.	Striæ are frequently to be found.

—(From Dorland's *Obstetrics.*)

To determine the date of confinement: Count back three calendar months from the first day of the last menstrual period, and add seven days.

3. *At three months:* Softening of cervix, cessation of menstruation, changes in the breast, discoloration of vagina, morning sickness. (None of much value, except the first.)

At six months: Hearing the fetal heart sound, active movements of the fetus, umbilical or funic souffle, outlining the fetus in whole or in part by palpation; ballottement (all valuable and all positive except the last).

4. See Williams' "Obstetrics" (1909), pages 441, etc.; or Hirst's "Obstetrics" (1909), pages 885, etc.

5. *Symptoms* of death of the fetus during the later months of pregnancy are: Cessation of the signs of pregnancy, the abdomen and uterus are both diminished in size, the fetal heart sounds and movements cease, there is no pulsation in the cord, the mother's breasts become flaccid and occasionally secrete milk. If the fetus has been dead for some time, crepitus of its cranial bones may be elicited. *Treatment:* Abortion or premature labor must be induced, and the contents of the uterus removed immediately. For details of methods see Williams' "Obstetrics" (1909), pages 376 and 381; or Hirst's "Obstetrics" (1909), page 799.

6. See Williams' "Obstetrics" (1909), page 815; or Hirst's "Obstetrics" (1909), page 577.

7. *Anteflexion* may cause sterility by stenosis or occlusion of the cervical canal.

Anteversion may also cause sterility.

Retroflexion may cause sterility, and may also hinder labor.

Retroversion may hinder labor, and if the uterus becomes incarcerated serious or fatal consequences may result.

During pregnancy any misplacement may cause pressure symptoms.

8. *Ovaritis and ovaralgia:* "Pain and tenderness are fairly constant in ovaritis; in ovaralgia there may be spontaneous pain, relieved or increased by pressure. Pressure on neuralgic ovary is often productive of hysterical symptoms, palpitation, globus hystericus, convulsions. Bimanual examination is negative in ovaralgia; in ovaritis the ovary is usually enlarged, often uneven in contour, and bound down by adhesions."—(Scott's *State Board Obstetrics.*)

SURGERY.

1. See Rose and Carless' "Surgery" (1908), pages 116 and 117; or Da Costa's "Surgery" (1908), pages 1052 and 1053.

2. "History of the tumor and its growth, whether congenital or acquired, and if acquired whether idiopathic or traumatic; rate of growth; absence of inflammation; location; age of patient."—(Scott's *State Board Surgery.*)

3. The patient should pass his urine into three separate vessels; if the urine in all three is similarly affected, the pus is from the kidneys; if most of it is in the first vessel, the pus is from the urethra; if most of it is in the last vessel, the pus comes from the bladder.

4. The most common seat of fracture of the clavicle is

COMA FROM INTRACRANIAL INJURY.	APOPLECTIC COMA.	UREMIC COMA.	ALCOHOLIC COMA.	OPIUM POISONING.
Deep coma; may have history of onset after fall or injury. Evidence of fracture of vertex or base.	Deep coma; sudden onset. If any injury, only a scalp wound.	Deep coma. Slow onset unless convulsions have preceded the coma.	Can be aroused by supraorbital pressure unless very profound.	Can be aroused unless very deep.
Pupil dilated on side of lesion. Choked disc.	Pupils unequal or dilated. Contracted in hemorrhage into the pons.	Albuminuric retinitis.	Pupils normal or somewhat dilated.	Pupils contracted to pinpoint size.
Pulse very slow.	Pulse full and slow, often arteriosclerotic high-tension pulse.	Pulse rapid.	Pulse more rapid than normal and full.	Pulse rapid, may be irregular.
Respiration slow and stertorous.	Respiration slow and irregular.	Respiration frequent and irregular.	Regular respiration.	Respiration very slow—may be 6 to 8 per minute.
Temperature higher—101°.	Temperature higher on paralyzed side, but lower in rectum.		May be low or normal.	
Urine normal or contains trace of albumin.	Urine contains trace of albumin, but may be same as in uremia.	Urine shows albumin, casts, and low urea percentage.	Normal.	Normal.
Hemiplegia on opposite side to that of injury. If contusion of brain is also present, may have generalized convulsions.	Hemiplegia with convulsions on one side.			

just external to the middle, at the junction of the two curves.

Sayre's method for fractured clavicle: "Sayre's dressing consists of two strips of adhesive plaster three and a half inches wide and two yards in length. The first strip is looped around the arm just below the axillary margin and is pinned or sewed with the loop sufficiently open not to constrict the arm. The arm is then drawn downward and backward until the clavicular portion of the pectoralis major muscle is put sufficiently upon the stretch to overcome the action of the sternocleidomastoid muscle, and in this way draws the sternal fragment of the clavicle down to its place. The strip of plaster is then carried completely around the body and pinned or stitched to itself on the back. The second strip is next applied, commencing on the front of the shoulder of the sound side; thence it is carried over the top of the shoulder diagonally across the back, under the elbow, diagonally across the front of the chest to the point of starting, where it is secured by pinning or sewing. A slit is made in this strip to receive the point of the elbow. Before the elbow is secured by the plaster it should be pressed well forward and inward."—(Wharton's *Minor Surgery and Bandaging.*)

5. See Rose and Carless' "Surgery" (1908), page 734; or Da Costa's "Surgery" (1908), page 696.

6. The table on page 468 (from Eisendrath's "Surgical Diagnosis") gives the diagnosis.

7. See Da Costa's "Surgery" (1908), page 573.

8. The arteries which need ligating in amputation of the middle third of the leg are: Anterior tibial, posterior tibial, and peroneal. For *method* see Rose and Carless' "Surgery" (1908), pages 342 and 343; or Da Costa's "Surgery" (1908), pages 420 and 421.

*No reciprocity recognized by these States.

†Applicants should in every case write to the secretary for all the details regarding the examination in any particular State.

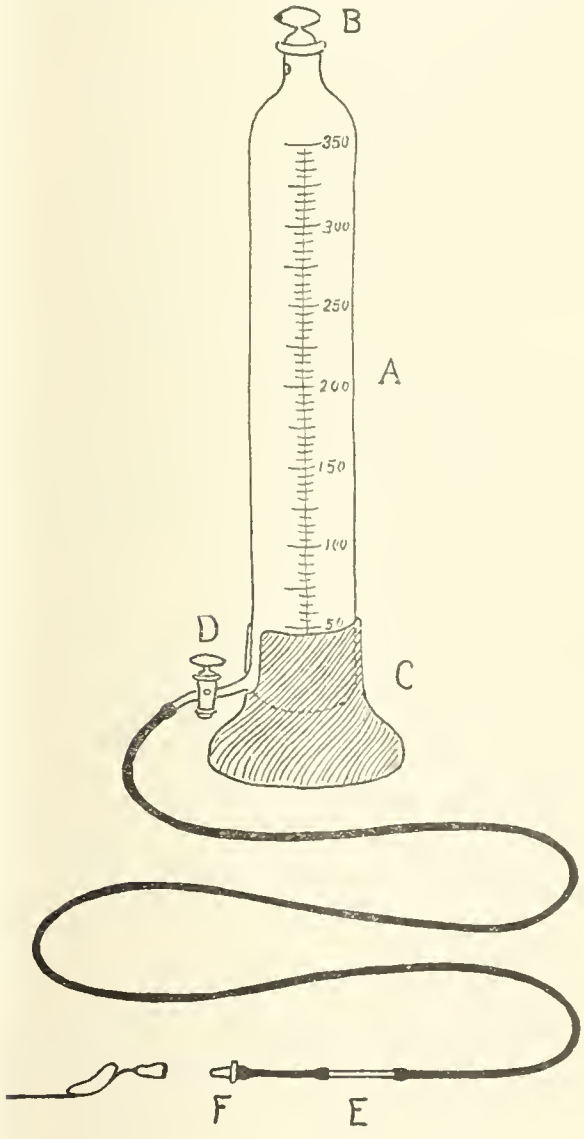
New York now reciprocates under certain conditions with:—Delaware, Indiana, Michigan, Ohio, Utah, Vermont, and Wisconsin.

New Instruments.

A SIMPLE APPARATUS FOR THE INTRAVENOUS INJECTION OF SALVARSAN.

By HOWARD FOX, M.D.,
NEW YORK
AND
WILLIAM B. TRIMBLE, M.D.,
NEW YORK

Owing to the large number of intravenous injections of salvarsan that are at present being given, it is highly desirable that the necessary apparatus should not only be efficient, but also as simple as possible. The Schreiber method, which we used at first in the service of Dr. George Henry Fox at



the New York Skin and Cancer Hospital, seemed unnecessarily complicated. An apparatus suggested by Dr. G. H. Semken was not wholly satisfactory and we have therefore modified the methods at first used and constructed a form of gravity apparatus which, in our opinion, considerably simplifies the operation of intravenous injection.

Our apparatus consists of a graduated glass cylinder (A) containing 350 c.c., which can be placed upon a table in an upright position in the detachable wooden base (C). The glass stopper (B) is pro-

vided with a vent so that air is admitted (to allow the escape of the contained fluid) by simply turning instead of removing it from the cylinder. The glass stop-cock (D) is fitted with a washer that retains it securely in place. A short glass tube (E) is inserted in the rubber tubing to allow detection of air bubbles and to avoid their entrance into the vein. At the end of the rubber tubing, which should be about 4 feet in length, a metal nozzle (F) is attached which fits in the Schreiber or other needle that is used. While the Schreiber needle is convenient on account of its form the caliber as a rule is too small, especially after the needle has been used several times and its interior becomes slightly rusted. Whether an ordinary straight needle or a Schreiber needle is used, we think it should have a No. 18 bore.

As the chief difficulty in intravenous injections of salvarsan is due to the proper insertion of the needle it is advisable to use only new needles or those with which the operator is well acquainted. The point should not be beveled too short, *e.g.* sharp pointed, for fear of wounding the vein after its introduction. As to whether the vein should first be exposed by cutting down upon it or whether the needle should be directly plunged through the skin into the vein is a matter of opinion. Where the operator has had considerable experience in performing venesection and is acquainted with his needle there should not be any difficulty in the majority of the cases in its proper insertion. In cases in which the veins do not become prominent after the application of a tourniquet or where the operator has not had any experience with venesection it is certainly advisable to make an incision and expose the vein. We prefer to introduce the needle through the skin into the largest accessible vein, usually the median basilic, a procedure that in our experience has not been followed by its obliteration.

In preparing the salvarsan for intravenous injection we have found it convenient to dissolve the drug in a small (25 c.c) glass cylinder. This is readily accomplished without the use of glass beads, which furthermore constitute a possible source of danger from the separation of small particles of glass. When ready for the injection the solution is poured into the large cylinder (A) and is diluted to 300 c.c. with sterile distilled water or physiological salt solution. We prefer the former as it is equally satisfactory and more easily obtained. If the salt solution is used it must be made up in the exact proportion of 0.85, or 0.9 of 1 per cent., as if for laboratory use.

After the thorough sterilization of the operator's hands and the patient's arm the needle is introduced into the vein and blood allowed to flow freely. The cylinder containing the salvarsan solution is then held by an assistant several feet above the patient's arm and the stop-cock (B) is opened. A little of the fluid is allowed to escape to see that it is free from air bubbles and the nozzle is then carefully inserted into the needle. The rapidity with which the fluid enters the circulation is regulated by the height at which the glass cylinder is held. Six or eight minutes are generally required for the 250 c.c. of fluid (the amount usually given) to flow into the vein. Before withdrawing the needle pressure should he made upon the point of injection with a piece of gauze and the needle rapidly withdrawn to avoid the entrance of an irritating solution into the tissues.

THE HYGIENE OF PUBLIC CONVEYANCES.*

By S. ADOLPHUS KNOPF, M.D.,

NEW YORK.

PROFESSOR OF PHTHISIOTHERAPY AT THE POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; ASSOCIATE DIRECTOR OF THE CLINIC FOR PULMONARY DISEASES OF THE HEALTH DEPARTMENT; VISITING PHYSICIAN TO THE RIVERSIDE HOSPITAL-SANATORIUM FOR CONSUMPTIVES OF THE CITY OF NEW YORK.

The hygiene of public conveyances would, perhaps, not be so important to us if we, as a people, were less fond of traveling, if our places of business and our homes were less remote from each other, and, last but not least, if our general public was more fond of walking.

Now, what are the public conveyances of which we must speak when discussing their hygiene? First, there is the ordinary railroad coach which carries us to and from our suburban homes and which the majority of people, unless they have to travel very long distances, use to reach their destinations. That many of these cars are overheated in winter and badly ventilated in summer is well known, though I am glad to acknowledge that some companies instruct their conductors to improve these unhygienic conditions as far as they can.

However, one of the almost universal and most deplorable conditions which are dangerous to health is found in the water closets of these so-called day coaches. There is neither trap nor water and the passenger, if obliged to make use of the water closet, must expose his body to a cold, often icy, draft. Since there is no flushing water, the feces often adhere to the walls of the basin. I wonder if to this condition a sometimes mysterious source of typhoid fever could not be traced!

To protect, not only the passengers, but also people living along railroad tracks, from the possible infection arising from water-closets, I wonder if something could not be done whereby the feces could be disinfected and rendered harmless before being allowed to fall to the ground? Some automatic disinfecting device would be the ideal thing.

The wooden cover of the seat, unless kept very clean, may be the means of transmitting the germs of venereal diseases (gonorrhea, syphilis), and also of various parasitic and other infectious skin diseases. Something which very tall persons might not notice, but which is a source of inconvenience to small and medium sized people, is the often unusual height of the seat, which makes it almost impossible for the small individual to exert the necessary abdominal pressure to help the free evacuation of the bowels.

If there are urinals, they are usually ill smelling because of lack of water, and because of little space in these compartments, they are usually in close proximity to the nostrils of the unfortunate passenger obliged to use the "water closet" in such a day coach.

Wash rooms are rare in day coaches. If there are any, water is often lacking and there is no soap nor towels. I have traveled a good deal in day coaches in my life, and to the best of my recollection I have never even seen a spittoon in a single one. I hope there are some in coaches in which I have not traveled.

We all know that most companies supply their day coaches with ice water and one drinking glass, which is often carried away by some gallant male passenger to give a drink to the ladies or the children. Sometimes it is promptly returned and sometimes it is not. Some companies have a metallic cup, fastened so that it cannot be removed. Do I need to say anything to an audience of this kind of the perniciousness, if not even criminal carelessness, of such practice? A better way of disseminating the bacillus of diphtheria among innocent children or of spreading among adults the tubercle bacillus, the pneumonia cocci, or the grippe germs is hardly conceivable.

The thorough cleaning and thorough airing of the passenger coaches at least twice daily when much frequented, and at least once, when the cars are usually less crowded, would seem the least the public has the right to demand from any railroad company. The cleaning of the upholstered seats and preferably the cleaning of the entire car should be done with the aid of the pneumatic process.

What remedies can be offered for the other evils? No railroad coach should be without a sanitary water closet which can be flushed easily and which should be constructed so as not to expose the passengers to becoming chilled when they use it on cold days. The water closet in a day coach should in every way be just as sanitary and comfortable as the one in a Pullman car. If for reasons of economy the company cannot afford to put in low and comfortable seats at once, let them at least place in each toilet room a little foot stool which will make up for the disadvantage of a high seat.

The water closet of the coaches should be separate from the wash room, just as in the Pullman cars. If, again, for reasons of economy, a sufficient number of clean towels can not be furnished, let the company furnish paper towels, which are inexpensive and can be disposed of by being burned afterward. Liquid or powdered soap in a receptacle is preferable to one piece of soap for all. It goes without saying that the wash room should always have an ample supply of water.

Of what earthly use is an ordinance saying "Don't spit" here or "Don't spit" there when there is no

*One of a series of lectures under the auspices of the Public Health Education Committee of the Medical Society of the County of New York and the Hygiene Committeee of the New York City Federation of Women's Clubs, delivered at the New York Academy of Medicine, February 15, 1911.

provision to spit somewhere. I firmly believe that a well-kept spittoon with a sign above it "SPIT HERE" will be more effective than all the ordinances beginning with "Don't."

Each coach should have, at least in each corner, a well-kept spittoon, with a wide opening, and partially filled with water. If I had my way I would have these spittoons fitted with a cover which could be easily manipulated with the foot.[1]

There is no gainsaying that the only rational way of preventing infection from the common drinking cup used in the railroad coaches is the use of an individual sanitary cup for every one. The new Pennsylvania Railroad station has installed a slot machine from which, with the aid of a penny, one procures an impermeable paper cup. How many of us would not gladly pay one penny more for our railroad ticket if we were sure that thereby infection from the common drinking cup in railroad cars could be forever removed? I have seen those impermeable paper cups distributed by insurance companies and enterprising business people to their policy holders or customers. The name of the company was printed on the outside of the drinking cup with their compliments. Evidently the small cost of these cups, when bought in very large quantities, will permit them to be distributed as a means of advertising, which does not in any way lessen their purpose of serving as one of the most important and useful devices to prevent the spread of infections and contagious diseases.

The parlor cars of our railroads are comfortable as a rule. They cannot be overcrowded because the seating capacity is limited and the ventilation can usually be improved upon by appealing to the conductor or the porter. There exists, however, one great nuisance in parlor and Pullman cars alike, and that is the brushing of passengers by the colored porter. The word nuisance hardly describes this practice unless we use the adjective "criminal" in front of it. The persistency with which this practice is carried on is, of course, explained by the fact that the colored porter expects a gratuity for this service from every passenger, ranging from 10 cents to 50 cents, according to the generosity, disposition, or the possession of ready change of the departing traveler. This brushing of the passengers in the middle of the car takes place at nearly every station where passengers leave, and the traveler who remains until the end of the trip will have had the benefit of having breathed all the dust that could be raised by the assidious porter from the garments of all his fellow passengers. A more sure way of irritating the respiratory mucous membranes with animal, mineral, and vegetable dust mingled not infrequently with all kinds of pathogenic microorganisms can hardly be conceived. Some companies have given orders that the brushing should be done in the corridors, and though this does not do away with the nuisance, it mitigates it to some degree. If I were a lawmaker or railroad president I would see to it that this practice would be stopped, and any attempt to renew it followed by the immediate dismissal of the Ethiopian employee. I would have a large sign placed conspicuously at both ends of the car, reminding passengers and porters that brushing was forbidden there. If, as it is sometimes said, the Pullman Car Company does not pay its colored porters sufficient wages, and that he is largely dependent upon the gratuities, or tips, he receives from the passengers (which, by the way, is hard to believe), then let this also be stated publicly. I firmly believe that I am not the only one who would gladly give the porter a quarter at the end of the trip on condition that his whisk broom would not be used on any of the passengers in the car. In justice to the car companies, we must, however, question whether, even if the salaries of the porters would be doubled, their desire for earning extra money by tips for perfunctory brushing would not still persist. The only way out of the difficulty, it seems to me, would be to use the automatic cleaner, not only for cleaning the Pullman car upholstery, but also the garments of the passengers. We must inhale enough dust at best in the car and should not be subjected to the additional amount which passengers may bring in with their clothes, and which may contain all sorts of pathogenic microorganisms. Even when sterile, this dust will, as stated above, cause an irritation of the respiratory tract, and there is no doubt in my mind that many a case of grippe and perhaps pneumonia or tuberculosis has had its origin in the inhalation of germs with this dust.

In the recommendation of the pneumatic process for cleaning the passengers' garments in Pullman sleepers and parlor cars, I do not stand alone. In a recent interview on the subject, no less an authority than Health Commissioner Lederle, of this city, expressed himself regarding this matter as follows: "The brushing of passengers in closed cars with whisk brooms is a nuisance, and the Pullman car people should take the matter up and see if some other way of brushing the passengers may not be discovered. The question has been discussed in scientific journals, and I have heard talk of legislation against the nuisance. I am inclined to favor the use of vacuum cleaners in the cars. If these cleaners were used the dust from the clothes would be drawn into receptacles."

The greatest amount of irritating dust comes, of course, from the smoke and cinders of the locomotives. In winter, when the windows are closed, this source of irritation of the respiratory organs is, of course, less, but in summer it is always a serious matter. Even cinders in the eyes have proved not infrequently a much more serious matter than is usually thought of at the time of the accident. Why, in a democratic country, only the passengers in Pullman sleepers and parlor cars can have the luxury of screened windows which will allow the entrance of air without the entrance of cinders is a matter for our lawmakers to settle. To my mind, the moment any passenger who has paid his fare enters a day coach he is as much entitled to protection from all kinds of accidents incident to the trip as the passenger in a sleeper or parlor car. It is devoutly to be hoped that the time will not be far distant when the traction power on all our roads can be supplied by electricity. I understand that on the Pacific Coast, where oil instead of coal is used to a very large extent, there is considerably less smoke, and, of course, no cinders. By emulating the example set by our California fellow citizens, there may be at least some improvement in these conditions on our eastern roads.

The condition of our sleeping cars has already been much improved. The fanciful carving is gradually making way for plain wood and the beds are usually made in such a way that the blankets do not come in contact with the sleeper. That there is not enough privacy in our American sleeping cars all of us are aware, and that the European method

of sections and small compartments is preferable all of us must agree. It is most encouraging that the number of sleeping cars with separate small compartments and the corridor on the side instead of in the middle is constantly increasing.

In the meantime some improvement could be made in the old style of Pullman methods of upper and lower berths, by having separate curtains for each bed. Ventilation would be improved thereby and more privacy would be assured also. These curtains should be of washable material or covered with such, which should be changed every night just as the sheets are changed. I venture to say that through this precaution preventable and communicable diseases would be much less propagated in railroad traveling.

It would be an advantage to invalids, to the traveling public in general, to the employees of the railroad companies, and to the companies themselves, to have specially constructed ambulance cars, in charge of a trained nurse, particularly for tuberculous patients going to and from much frequented health resorts and sanatoria. Surely everyone would gladly pay his little share of the increased cost, for the sake of self-preservation, and the invalid for the sake of comfort.

It is stated by some authorities that people who clean cars frequently become tuberculous.[2] This could also be mitigated if the traveling public would help the companies by cooperation, by observing the same good manners regarding expectoration and cleanliness when in a railroad car that they are accustomed to observe in their own homes. Spitting on the floor of public vehicles is a crime against one's fellowman.

The lighting by electricity of all railroad cars, not only of the few special trains, will have advantages. That many a serious accident might be avoided by the replacing of gas by electricity should be an inducement to all railroad corporations to inaugurate electric lighting for all their passenger cars.

The lighting of passenger cars should be so arranged that any passenger desiring to read can do so without straining or spoiling his eyesight. Soft, light colors which are known to be helpful in increasing pleasant and efficient lighting should be used to paint the interior of passenger cars.

What has been said about the drinking cup in the coaches is, of course, also applicable to the drinking glass in parlor and sleeping cars.

There is one more unsanitary custom to which I should like to call attention. I refer to the practice of having the fruit and sometimes the candy which is offered for sale in the cars left uncovered, often for hours, if not all day.

We come now to what, as city people, concerns us particularly—our elevated, surface, and subway cars. These are the vehicles which we use most. If it was not for the frequent overcrowding and the difficulty of getting in and out of our elevated cars, I would consider this mode of transit, in the City of New York at least, the best and most comfortable and sanitary. The air in the elevated trains is usually not bad, and expectorating on the floors is not nearly as frequent as formerly. But how vastly would the comfort be increased if the elevated railroad company would decide to have also sliding doors in addition to its narrow gates, to facilitate the entrance and exit of the passengers. Of course, the leather straps—and they will be needed as long as there will be strap hangers—should make room for the more sanitary and cleanly celluloid covered handles, already in use in a few surface and subway cars.

Our surface car hygiene is not so bad, and if the passengers will help in the efforts of the companies to keep the cars clean, much discomfort, bad sanitation, and uncleanliness can be avoided. Thus, for example, our surface car companies have of late caused to be printed on the back of their transfers the following request:

"CLEANLINESS OF CARS is impossible of accomplishment without the cooperation of all concerned. We ask you to assist us in keeping the cars clean. Will you do your share by refraining from leaving in, or upon, the cars newspapers, scraps, cigarettes, or cigar stumps, peanut shells, etc.?"

A similar notice appears occasionally, warning the smoking gentlemen not to bring into the cars their ill-smelling and smoking stumps. It reads as follows:

"NOTHING IS MORE OFFENSIVE than stale, half-smoked tobacco to women and children, and to all those who do not smoke. It is very disagreeable even to smokers who may not be smoking at the moment. Thoughtlessness alone permits the bringing of half-burned cigars or cigarettes, etc., into a street car."

What has been said of the celluloid covered straps being desirable in the elevated trains is, of course, also applicable to the surface cars.

When one travels in a street-car on a hot dusty day when the windows and rear door are open, he will inhale so much mineral and vegetable dust drawn into the car by the back draught caused by the rapid motion of the vehicle, that he will wish that the street-car companies were obliged by the health authorities to sprinkle their tracks regularly whenever conditions make this desirable. In other cities one sees sprinkling cars manipulated by the electric surface road. Thus far I have not seen any such practical devices in New York City.[3]

I would not fulfill my duty as a sanitarian and my efforts to protect passengers from diseases and accidents caused by travel would be incomplete if I did not say a word, and as strong a word as I can find, against the absolutely dangerous and well-nigh criminal habit on the part of the ladies of fastening their gigantic hats with still more gigantic hatpins, the points protruding several inches, ready to pierce anything from the unoffending felt hat to the eye of the fellow traveler. Verily, it is time for anti-hatpin legislation.

That some of our ferryboats need more sanitation we are all very well aware. But here, again, the public and the companies must work hand in hand.

Somewhat different is it with our coast steamers plying between New York and Boston and other ports. On the former particularly I have seen any number of mattresses laid in the gangways, corridors, and salons of those magnificent ships, to accommodate passengers who could not be accommodated in cabins. That this mode of travel is neither hygienic nor sanitary is self-evident, and some legislative measures preventing such overcrowding might well be considered.

I must say a last word concerning the prevention of the spread of respiratory diseases, which is applicable to traveling in all kinds of public vehicles —railroad cars, surface, subway, and elevated cars, ferryboats, etc. I refer to the danger of droplet infection. To my mind, to prevent the propagation of any respiratory disease it does not suffice to stop

indiscriminate expectoration. There certainly exists quite a good deal of danger from what is known as droplet infection, or infection from bacilliferous drops expelled during coughing and sneezing. Imagine a crowded car at the time of a grippe epidemic, when half of the people cough almost incessantly without holding their hand or handkerchief before their mouths to prevent the spray or droplets containing Pfeiffer's grippe bacillus to fall upon the neighbors' garments, or even in face. From what we know from experimental work it is absolutely demonstrated that the wrongly called dry cough of the tuberculous, which is only called dry because it is not accompanied by expectoration, but which is always accompanied by the expulsion of drops of saliva, not infrequently containing bacilli, is an absolute factor in the propagation of tuberculosis. Let us educate the masses to this sort of infection, and particularly the traveling public. Let our Health Departments' placards incorporate in the anti-spitting regulations what might read about as follows:

"In order to prevent the propagation of infectious diseases of the lung and throat, one should always hold his hand or handkerchief before his mouth during the act of coughing." [1]

The small particles of saliva which may contain the germs are thus prevented from doing harm to others.

We all know what a serious discomfort the average American city dweller suffers because of lack of comfort stations. This is particularly felt at end and transfer stations in isolated city districts. Surely, this condition could easily be remedied with relatively little expense by all surface car companies. One feature should, however, be characteristic of all public water closets, including those on railroad cars, and that is, they should be so constructed that the sexual organs could not come in contact with the wooden seat. A number of such ideal sanitary closets, which can be kept scrupulously clean with relative ease, are already in the market, and the replacing of the old, dangerous type by this modern and sanitary one should be made obligatory.

It doubtless is not possible to replace the old unsanitary water closets on railroad cars and in public comfort stations with the new type at once, in view of the large number existing of old types of closets. Nevertheless, something very simple could be done, namely, to cover the seat with a sheet of paper cut to fit. Such seat covers are in use in many European comfort stations, where a small fee is charged. Because of such a protective paper seat, covering the entire rim and so shaped as to prevent the sexual organs from coming in contact with the wooden seat, the contraction of any infection becomes virtually impossible. The cost of such paper cover will be a fraction of a cent. With the aid of a penny-in-the-slot machine a municipality or railroad company could easily cover the additional expense of safeguarding the public against infection often of a very serious nature.

The hygiene of the subway is a subject so vast that I feel I cannot do it justice in the short space of time allotted to me for my paper. It has been studied most carefully by one of our best sanitary authorities. In Dr. Soper's recent paper on "The Contamination of City Air," read before the Sanitary Section of the Association of Engineering Societies,[4] which it was my privilege to discuss,[5] you will find a profound study of the bacteriological, chemical, and physical condition of our subway air. I will quote from the admirable paper of Dr. Soper only a few sentences. He says: "Rush hours in the subway always gave larger amounts of carbon dioxide than other hours." In speaking of the character of the subway dust, which he found as the result of many an analysis, he says: "The subway dust was of peculiar fineness. Many of the particles were sharp, flakelike, and angular. There was over 60 per cent. of iron in it." As a result of careful examination of several hundred men working in the subway and pursuing other occupations, Dr. Soper came to the conclusion that there was a marked excess of dry pleurisy among the subway men. To limit the danger arising to the employees of the subway, I have suggested in previous writings that these workers should alternate in their shifts with the workers on surface and elevated cars.

The ventilation of the subway is still in a stage of experimentation. Whether more airholes, the pumping in of fresh air with the aid of specially constructed pumping stations, the building of partitions between incoming and outgoing trains in order to produce opposite currents of air, and in addition the removal of all obstructing signs fastened to the railing of the stairs will ultimately prove sufficient to make the air in the subway reasonably free from an excess of carbon dioxide and other not yet determined, but deleterious, products of exhalation is a matter too vast to discuss in this paper.

To limit the discomforts and danger from overcrowding in the subway, I do not know of any other remedy than more subways, more trains, better service, more gentle handling of the masses by the special policemen assigned to keep order. The other day, when riding in the subway, I listened to the argument of two citizens about the overcrowding of all our city traffic system, but particularly the subway. The conclusion of one was that it would take the angel Gabriel to prevent overcrowding in the subway, and that we might just as well submit to the inevitable. This might be good philosophy, but it would not be good policy.

Many perils are connected with the overcrowding of our subway. The accidents to life and limb due to overcrowding are numerous. A recent editorial in *American Medicine*[6] points to another danger, which the writer calls "the temper of the subway crowd." I cannot do better than to quote from this admirable contribution to the hygiene of public vehicles. Justly deprecating the possible danger that there is of an increase of deafness as a result of the development of subways in our large cities, he makes the following significant statement under the caption, "The Real Subway Peril":

"Up to a short time ago the mental condition of the people using the subway was entirely different. There was a disposition to take the inconveniences and annoyances of overcrowding good-naturedly, and to meet presenting conditions with good humor. There was safety in such a psychological atmosphere, for it betokened tolerance and temperate consideration. But a vast change has taken place within a year. It would almost seem that the people were actually more fatigued, they are so much more irritable. Whether this is the result of continued overcrowding or comes from other causes, no one can say. Instead of good nature, there is a sullen pugnacity that seems always close to the surface, ready to break out at the slightest provocation. Nor is this confined to the classes of individuals who would be most expected to show such characteristics.

Ladies and gentlemen bearing every evidence of culture and refinement seem as ready as the roughest and most uncouth to show the spirit of intolerance. Difficult as it is to account for the remarkable change that has taken place in the psychology of subway travelers, no one can come in touch with present conditions without observing, or rather feeling, the pent-up state of the crowds. . . . If existing conditions can so profoundly affect people of sound mental balance and cultured temperaments, as they certainly have, how much greater influence must these same conditions exert on the mentally susceptible and unsound? It is only a step sometimes from the sullen pugnacity of an ill-tempered crowd to the hysterical frenzy of a mob. That such a condition if allowed to continue will lead to a calamity that will leave another blot on our vaunted civilization is scarcely to be doubted. It is to be hoped, therefore, that the subway situation may be soon relieved, if for no other reason than to keep our people from disgracing themselves by some frightful display of subway temper or mania."

My paper would indeed be incomplete were I not to refer to a distressing condition, viz.: the many preventable accidents caused by surface cars. The Public Service Commission reports that 48,013 persons were injured in accidents on the various surface roads throughout the five boroughs of New York City during 1910, of whom two-thirds were passengers, one-sixth pedestrians, and one-sixth employees. Of the total number of accidents, 2,874 were serious, 377 being fatal. In addition, 72 persons lost a limb and 379 suffered broken limbs.[7] Some of these accidents might have to be considered unavoidable, but I am reasonably certain that many could have been prevented. No car should run in a city without a safety device or fender. The high steps should be replaced by lower and more convenient ones. Particular care should be exercised with the very long cars when turning curves. Motormen and conductors should not be overworked, so that overstrain and overtiredness could not be put forth as an excuse for street-car accidents due to negligence on the part of the employees. To be fair, let us, however, again point to the necessity of cooperation on the part of the public. When comparing the above published statistics with European figures, I cannot quite agree with the statement that has been made that the chances of accidents on our street cars are very slight. Nevertheless, the following warning appearing from time to time on the backs of the transfers is opportune and should be helpful in rendering accidents less frequent:

> THE CHANCES OF AN ACCIDENT ever happening to YOU on a street car are very slight. Figures prove that. But you can reduce that very slight possibility practically to a vanishing-point by being careful, watching where you are going, waiting until the car stops, alighting only when facing the front, etc.

Why there should be ten times as many railroad accidents in the United States as there are in Europe is a matter which can only be explained on the ground that the managers of our American railroad companies must be less careful in their traffic regulations, that the employees are either overworked or not carefully trained and selected for their duties, and last but not least, that the many safety devices which are invented in the country and in Europe, but mainly in use in Europe, are not sufficiently employed in America.

That there is great room for improvement, that much could be done to make railroad travel in this country at least as safe as it is in Europe must be admitted, and it is sincerely to be hoped that conditions will be improved. If it is found impossible for this to be done by the initiative of individual companies then legislative control or government supervision of railroads will be the only alternative.

From what I have said in the preceding pages on the prevention of the spread of diseases of all kinds, and on the possibility of reducing accidents to life and limb, you should be convinced how much there is for us to do. Let us as true sanitarians and true doctors teach whatever we know that will improve existing conditions. Let us appeal in kindness, but in all earnestness, to the directors of our subway, elevated, and street car companies for relief from the most striking sanitary defects, and assure them that there is much that can be done immediately. If that fails, then it is our duty to appeal to legislative help for relief, and remind our city fathers that health is wealth, and the more a community strives toward the improving of the health of its citizens the greater will be its sanitary, even financial, intellectual, and, above all, its moral gain.

THE IMPORTANCE OF THE THREAD IMPREGNATION TEST FOR THE RECOGNITION OF ULCERS OF THE UPPER DIGESTIVE TRACT.*

BY MAX EINHORN, M.D.,

NEW YORK,

PROFESSOR OF THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

IN two previous papers I[1] [2] have published my results with the thread test in ulcers of the upper digestive tract. In view of the fact that considerable difficulty exists in making a positive diagnosis of ulcer of the stomach this new test, permitting us, as it seems, to recognize more clearly the existence of an ulcer, appears to be of value.

Dr. Morgan[3] of Washington studied this method in a considerable series of cases and found it very useful.

Von Barth-Wehrenalp[4] likewise tried the duodenal bucket in a number of cases with two objects in view, one to ascertain whether duodenal contents can in this way be obtained, secondly, whether the thread in case of ulcer will show a bloodstain. He arrived at the conclusion that while it is possible in more than half the cases to obtain the duodenal contents with the bucket there was never in his

*Read before the Tri-County Medical Association, on November 15, 1910, at Morristown, N. J.

cases of ulcer of the stomach or duodenum a bloody discoloration on the thread.

This apparently very remarkable contrast to my own and Dr. Morgan's findings can be easily explained. In applying the thread test for ulcer it is necessary to introduce the bucket at night before

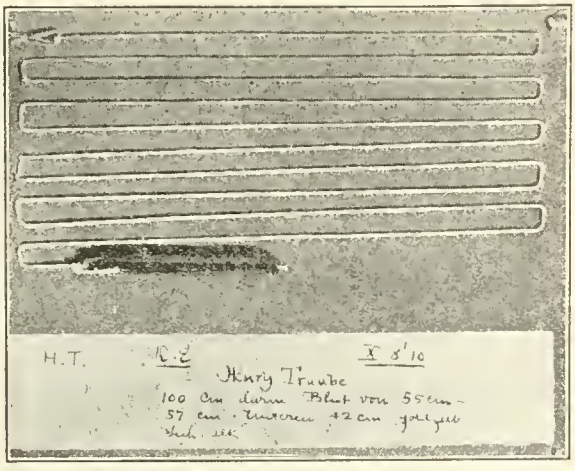

Fig. 1.—Case 19. Before treatment.

retiring and leaving it in the digestive tract until the following morning, or the bucket must remain there nine to ten hours. Dr. V. Barth-Wehrenalp, however, did not conform with these requirements for he states distinctly: "the bucket was swallowed at seven in the morning by the patient in the fasting condition, the drinking of a small quantity of water being permitted in case it could not otherwise be swallowed; at ten in the forenoon the bucket was again withdrawn." In this way the bucket remained only three hours in the digestive tract after having been introduced with a small quantity of water. Hence the bucket occasionally had no chance of leaving the stomach and when it did leave the thread did not have enough time to become impregnated with blood from the ulcerated area.

In the present paper I have tabulated my recent experiences with the thread test (October, 1909-October, 1910). In this table are contained thirty

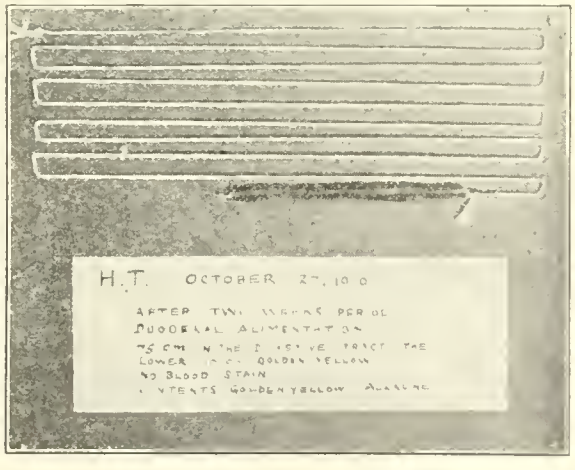

Fig. 2.—Case 19. After treatment.

cases of ulcer of the stomach and duodenum, one case of cirrhosis of the liver, and five cases of gastric cancer with ulceration. In the cases described the diagnosis of ulcer had to be made by the presence of most of the clinical symptoms with or without hemorrhages. Only two of these cases were operated and the ulcer found at a corresponding spot stated by the thread test (Cases 21 and 13). At this point I would like to remark that an operation can prove only the correctness of the diagnosis, but if at a laparotomy no ulcer is found after a visual examination of the stomach without open-

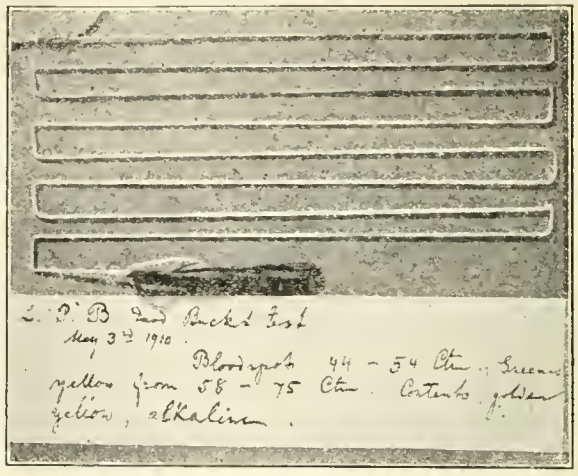

Fig. 3.—Case 30. Before treatment.

ing, then this is an insufficient proof that an ulcer does not exist. For it is clear that only those ulcers can be recognized by the surgeon which are of long standing and have already undergone marked changes, while small fresh ulcers involving only the gastric mucosa and part of the submucosa cannot be recognized without opening the stomach.

In a number of cases the test has been made several times; usually the results harmonize. Sometimes, however, there is a difference in the site of the brownish spot. This may be explained by the patient's involuntary pulling the thread somewhat out of position during the process of washing and dressing. There is at times a very long brownish discoloration for a great distance. This need not correspond to the size of the ulcer and can be easily explained by different parts of the thread coming into contact with the ulcer successively during the migration of the bucket through the py-

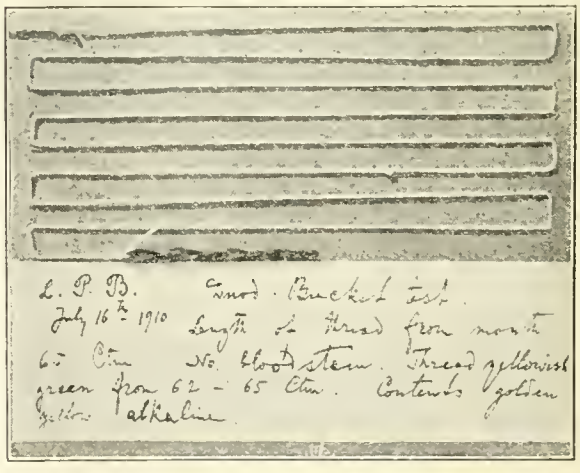

Fig. 4.—Case 30. After treatment.

lorus and the duodenum. This is particularly noticed in malignant disease of the stomach, which as a rule presents fresh ulcerations.

The thread test appears to be of importance not only in the recognition of the position of an ulcer, but also as a criterion of the efficacy of our pro-

						Vomited bucket after one-half hour.

cedures, especially whether a cure has been accomplished or not. In those cases in which perfect healing of the ulcer has taken place the test becomes negative. As an example of this sort we may mention Cases 19 and 30. (See Figs. 1 to 4.) In Case 14 after two weeks' duodenal alimentation there were only two minute spots left showing that the healing had almost been completed.

Cases 24-29 embody six instances of gastric hemorrhages in which the thread test proved negative. In two of these the hemorrhages had taken place 12 and 15 years ago respectively. There is a probability that the ulcer had meanwhile healed. In the remaining four cases the ulcer probably was situated at the fundus or the greater curvature of the stomach.

In the diagnosis of cancer of the stomach the thread test is of value in aiding us to recognize a suspected neoplasm before it is yet palpable. This is particularly the case in malignant affections of the cardia and the pylorus. In a case of cancer of the cardia the bucket returned once filled with a piece of tissue of the tumor showing microscopically all the characteristics of a cancerous growth, while the thread above showed a blood stain. In several cases of neoplasm of the pylorus the bucket did not pass beyond the pylorus and came back filled with a brownish fluid of a fetid odor, the thread being discolored brownish for quite a distance from the bucket.

The ease with which the thread test may be made and its usefulness with regard to informing us of the permeability of the pylorus and the presence or absence of ulceration along the upper digestive tract should promulgate the frequent use of the duodenal bucket in chronic digestive disturbances.

TWO CASES OF AINHUM.

By TRUMAN ABBE, A.B., M.D.,
WASHINGTON, D. C.

One of the tropical diseases that is becoming more evident in the temperate zone is the condition leading to the autoamputation of an extremity, most frequently the end of the little toe. This condition called Ainhum, was first described by Da Silva Lima, of Bahia, Brazil, in 1866, and soon thereafter reported from India and East Africa. There have been reported in the literature from the United States about thirty cases, mostly from the gulf States and the Carolinas, some of doubtful diagnosis. Only one has before this been reported as seen in the District of Columbia. That was by Dr. Pyles in 1895.

The cases have occurred almost exclusively in the dark skinned races, negroes and hindoos, and are said to be much more common in men than in women. One reason that these cases are not noticed more often is the fact that the condition may run its entire course with very slight discomfort. That a toe is merely dropping off by degrees is not enough incentive to bring the ordinary negro to a physician. When a painful ulceration occurs the condition demands notice and may bring the patient to the doctor.

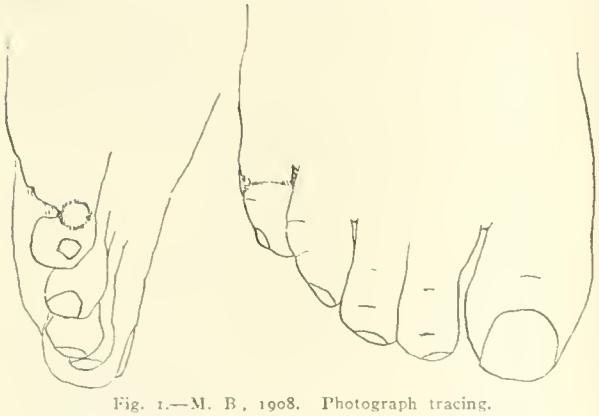

Fig. 1.—M. B., 1908. Photograph tracing.

As described, there is no constitutional disturbance associated with the toe amputation aside from certain vague conditions that are attributed to trophoneuroses of the skin. The attempt at autoamputation occurs most commonly at or near the proximal interphalangeal articulation of the little toe as a deepening groove. On the dorsum of the toe, in this groove, may be a corn-like callus.

In the early stages the bones are not involved. The middle phalanx seems to be involved first. In the later stages there is said to be a conversion of the bony structures into fibrous tissue and then, after from two to forty years, the toe drops off. In the recorded cases the few excellent skiagraphs, where they have been reproduced, show the same type of bone change as in the two cases about to be reported. One case in which the skiagraph was described, not reproduced, seemed to show a different bone process—a rarefying ostitis with cavity formation.

The two cases reported herewith came independently during the month of October, 1908, to the Surgical Dispensary of Garfield Hospital, in Washington, D. C., on account of pain in the deep plantar fold under the little toe. We relieved the pain in each instance by a simple immobilizing dressing, had skiagraphs taken by Dr. Merrill, for record and diagnosis, and have watched the two cases for two years. In the earlier case the surface appearances did not materially change, though the groove under the toe was distinctly deeper. The changes in the deeper structures also were slight as the skiagraphs showed merely a slight atrophy of the proximal phalanx. In the more advanced case the surface changes were somewhat more evident in the increased depth of the groove, but the rate of development was not much greater than in the other case. Two years in each case had made but little advance in the progress of the amputation.

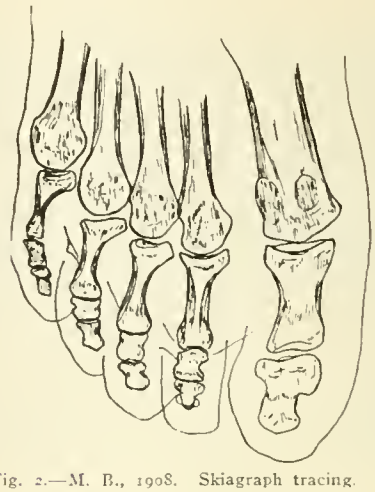

Fig. 2.—M. B., 1908. Skiagraph tracing.

Case I.—M. B., a negress, 38 years of age, native of Maryland, came to the Garfield Hospital complaining of pain in her right little toe. For sixteen years she had had what she called a corn near the base of the toe and for two years she had been having pains under the toe. With the beginning of the pains she had noticed a groove under the toe. The examination, in October, 1908, showed that there was a distinct rounded callus on the outer side of the little toe on the dorsum, a slight depression across the back of the toe, and a deep groove on the plantar surface (Fig. 1). The skiagraph showed just a possible beginning absorption of the base of the middle phalanx lying just proximal to the skin groove (Fig. 2).

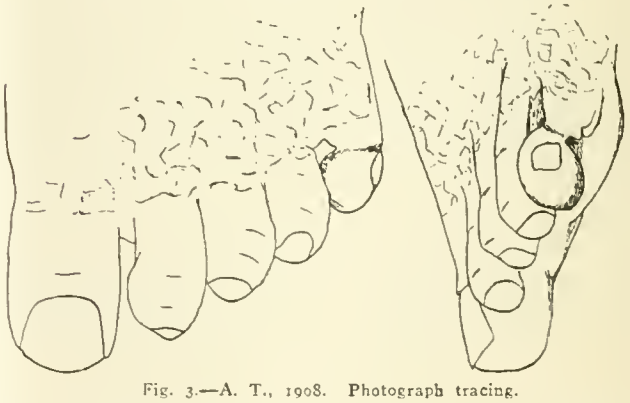

Fig. 3.—A. T., 1908. Photograph tracing.

On September 1, 1910, after an interval of two years, during which the toe had given very little trouble, except for the pains in the groove under the toe, caused by bending the toe up and cracking the thick skin, we took a second skiagraph. The surface conditions showed practically no change.

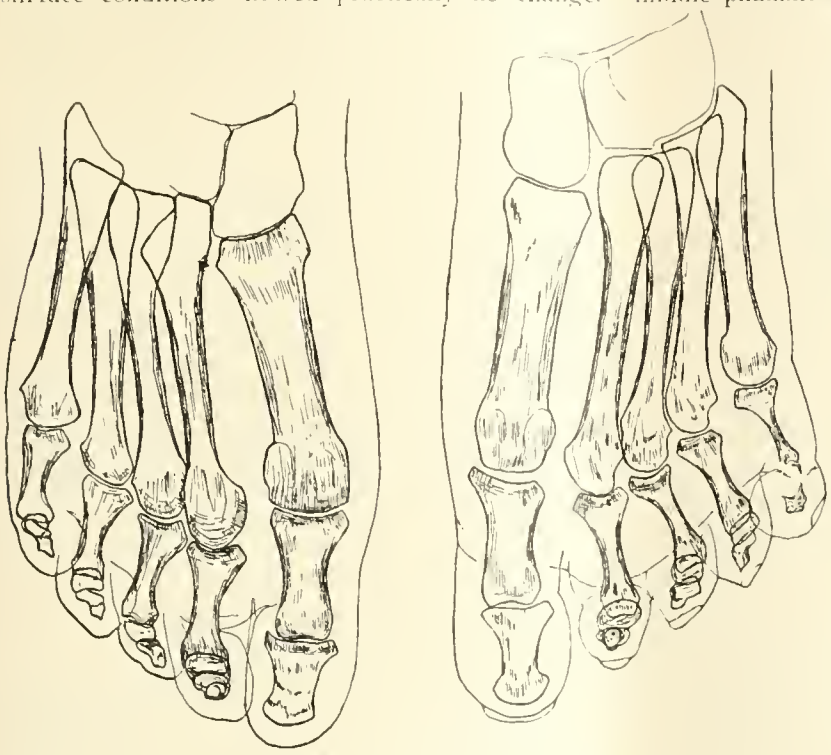

Fig. 4.—A. T., 1908. Skiagraph tracing.

There had been but slight deepening of the groove. The skiagraph taken at this time showed no further absorption of the middle phalanx, though it had become united to the ungual phalanx by bony union, which had not been noted in the previous examination and did not appear in the prior skiagraph. Measurements of the bones in the two skiagraphs showed a variation in the length and width of all the longer bones by a fraction of a millimeter, due to the differences in technique in the two pictures. The diameter of the basal phalanx of the right little toe, however, was decreased more in proportion than any of the other bones by nearly a millimeter

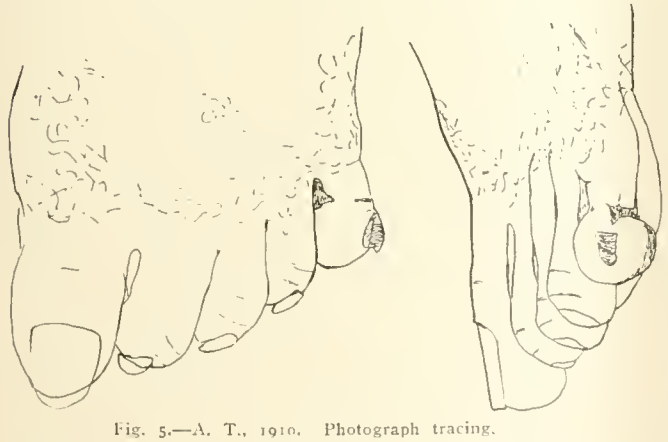

Fig. 5.—A. T., 1910. Photograph tracing.

and the medullary cavity had disappeared in the middle of the bone (Fig. 7).

September 10, the toe was amputated under cocaine and, according to the patient, caused less pain than frequently came from walking on the toe. The wound healed uneventfully. Examination of the removed toe, grossly on longitudinal section, showed the deep groove in the plantar fold with its thick walled ulceration the size of a millet seed. The proximal phalanx seemed small, but not abnormally so. The joint edge of the base of the middle phalanx was thin and rough; not rounded as in the normal bone. The middle and ungual phalanges were fused into one, as is not uncommon in apparently healthy toes. The joint line in the latter skiagraph was much narrower than in the early picture, indicating that the ankylosis, if existing two years before, had then been fairly recent.

Case II.—A. T., a negress, 48 years of age, born in Augusta, Ga., had for fifteen years been a resident of the District of Columbia. She came to the hospital also in October, 1908, and also complained of pain in the furrow under the little toe on her left foot. The toe had been troublesome since childhood. She said it always had been her "game" toe. For fifteen years or more she had noted the constriction near the base of the little toe, deepest internally and on the plantar surface. Occasionally she had had pain in it and the toe was at times tender, tingled, or felt numb. No other toes had bothered her. No one else whom she knew ever had had such a toe. She had never had a corn on any toe. There was present a scaly condition of both hands and feet, extending on arms and legs, which had been present since her earliest recollection. She was somewhat flat-footed. There were a number of old scars on her legs, said, however, not to be due to any ulcers. She had had seven children, only one of whom had lived beyond seven months, and that boy was not up to his mother in mental ability, though he showed no definite sign of disease. The cause of death of the other children did not, in fairness, suggest syphilis.

Examination of the toe in October, 1908, showed (Fig. 3), a slight transverse groove on the outer side and the dorsum of the toe. On the plantar surface there was a deep sulcus cutting down almost to the toe nail. The end of the toe beyond this sulcus was bulbous, but only slightly larger than the corresponding portion of the little toe on the right foot, which seemed to be normal. There was no evidence of any corn-like callus in the line of the groove. The skiagraph (Fig. 4) showed the outline of the toe and marked absorption of the bone at and on both sides of the groove, which was not opposite a joint, but the middle of the middle phalanx of the toe. In the ungual phalanx the structure of the bone was normal for the portion bearing the nail, but the base of the bone had been absorbed, except for a part of the shaft on the outer side. The middle phalanx was all gone except a bit of the base and the outer edge. The proximal phalanx had been absorbed for fully two-thirds of the diameter of the head on its inner aspect and the shaft had atrophied until it was not more than one-half the diameter of the normal bone

as shown by comparison with the corresponding bone on the right foot. We have called this an atrophy of the basal phalanx because, while the bone was but one-half its normal diameter, yet it still showed the normal shell formation, indicating that there had been no erosion from the surface of

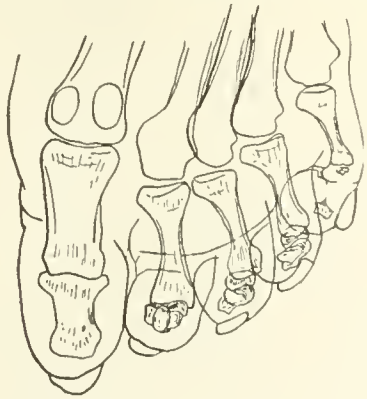

Fig. 6.—A. T., 1910. Skiagraph tracing.

the bone, but a distinct change in the growth of the bone. It was noted, too, that this atrophy was fully two centimeters proximal to the site of autoamputation—the groove. The bones of the other foot were apparently normal.

In October, 1910, we again examined the foot. The surface showed (Fig. 5) a deeper groove laterally and on the plantar surface, but very little change on the dorsum. There had been no painful ulceration in the furrow. The mobility of the tip of the toe was great, but there was enough rigidity to hold the toe in place under ordinary circumstances, though any manipulations tended to tear off the toe tip. Hence the toe nail had not been cut for months and showed a pyramidal heaping up of the horny layers into a nail as thick as it was long.

The skiagraph (Fig. 6) showed the extension of the fold and the increased absorption of the bone. In the ungual phalanx the nail-bearing portion of the bone was all that remained, though that seemed normal. All the base was gone. The middle phalanx was represented by a nodule the size of a pin head at the base. The proximal phalanx was in practically the same condition as two years previously—about one-half the normal diameter. There were no evidences of change in the bones of the other foot.

The patient complained of no further pains in the

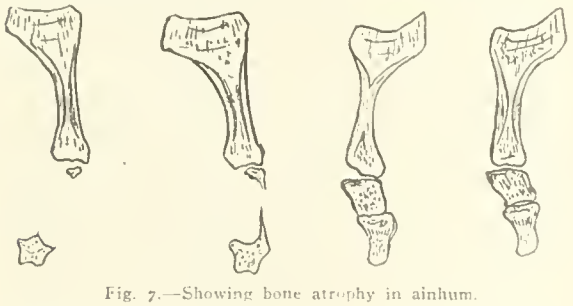

Fig. 7.—Showing bone atrophy in ainhum.

toe and did not care to have the toe amputated. Hence it remains to amputate itself.

In examining the tracings from the skiagraphs it will be noted that the toes are not straight, but bent over at the ends, so that the ungual phalanges of all the toes tend to be almost perpendicular to the plate, and that the tips of the toes tend to point towards the great toe. Tracings from the skiagraphs have been reproduced, rather than photographic prints, in order to emphasize the salient features and eliminate the unessential details that confuse the photograph.

We have grouped together (Fig. 7) the bone pictures at the four stages represented in the two observations on each of the two cases. They suggest that possibly the bony atrophy of the proximal phalanx preceded other bony changes, though even that was not apparent until after the groove in the skin had existed many years. The site of the autoamputation of the toe is marked by a groove, not a constricting band, and there is no evidence that the increase in connective tissue is the cause of the condition. On the contrary, in view of the fact that the bony atrophy proceeded proximal to the groove it would seem as if there were some general cause for the atrophy and autoamputation arising nearer to the trunk and that the loss of the toe is not the essential lesion in the process, but merely the result of some other lesion. The cases that have been reported in the literature of second and third higher autoamputations, following the primary digit autoamputation, are in the same line supporting the view that the primary lesion is what we call a trophoneurosis.

Stonleigh Court.

NON OCCIDES.*

By AUGUST ADRIAN STRASSER, M.D.,
Arlington, N. J.

This commandment in its Latin dress is so pertinent a heading for such a paper as the present and the one by Prof. Dr. L. Knapp in *Volkmann's Vortraege* that I have adopted it as the title of this essay. If this be plagiarism I plead guilty.

Before entering into the more intimately relevant questions concerning the legal and medical phases involved in this theme I thought it of interest to bring out the historical and the religious aspects of the subject and observe from what the present-day attitude has evolved. Previous to the decadent morality of classic Greece, there is no mention of criminal abortion. The fact that Moses, the great legislator, fails to mention it, points to its probable absence among the Israelites and the surrounding nations; and even in the long enumeration of sins laid to the charge of the Canaanites (Leviticus, Chapters xviii-xix-xx) it is not referred to. The oath of Hippocrates distinctly binds the physician to give no means to procure abortion. The early Christians are the first on record to pronounce abortion to be the murder of human beings; their apologists, Athengoras, Tertullian, and Minutius Felix, to refute the slander that a child was slain and its flesh eaten by the guests at the Agapoe, appealed to their laws as forbidding all manner of murder, even that of children in the womb. The Church Fathers unanimously maintained the same doctrine and the various councils, such as that of Eliberis, in the fourth century, and the Sixth Ecumenical Council, punished the crime as if it were murder, and as Lecky, the historian, says, "The stern sentences to which the guilty person was subjected impressed on the minds of the Christians more deeply than any exhortation a sense of the enormity of the crime." As a direct outcome of this doctrine the Church of Rome has given fairly definite legislation on the subject, dividing abortion into two categories, de-

*Read at a meeting of Physicians' Club of Newark, November 11, 1910.

fining that "performed to save the life of the mother, obstetrical abortion; that brought about for social reasons, criminal abortion." With regard to obstetrical abortion all such moral questions when they are submitted are decided by the tribunal of the Holy Office, and we would here note, with regard to decisions of this tribunal, that while they claim the respect and loyal adhesion of all Catholics, they are not irreformable, since they are not definite judgments, and do not proceed directly from the Supreme Pontiff, who alone has the prerogative of infallibility. This authority decreed May 28, 1884, and again August 18, 1889, "that it cannot be safely taught in Catholic schools that it is lawful to perform any surgical operation which is directly destructive of the fetus or the mother. In another decree of July 24, 1895, abortion was condemned by name. The question submitted was whether, when the mother was in immediate danger of death and there was no other means of saving her life, a physician can with safe conscience cause abortion, not by destroying the child in the womb, which was implicitly condemned in the former decree, but by giving it a chance to be born alive, though not being viable, it would soon expire." The answer was "that he cannot." This and similar decisions caused some moralists to doubt the wisdom of the ruling, and it was asked whether an exception in the case of ectopic gestations could not be made. Therefore, the question was submitted, "Is it ever allowed to extract from the body of the mother ectopic embryos, still immature, before the sixth months after conception is completed?" The answer given March 20, 1902, was: "According to the decree of May 4, 1898, as far as possible, earnest and opportune provision is to be made to safeguard the life of the child and of the mother. As to the time, let the questioner remember that no acceleration of birth is licit unless it be done at a time and in ways in which, according to the usual course of things, the life of the mother and the child be provided for. The Church agrees with Ethics, and teaches that no action is lawful which directly destroys fetal life. But also holds that if medical treatment or surgical operation necessary to save a mother's life is applied (though the child's death would, or at least, might, follow as a regretted but unavoidable consequence) it should not be maintained that the fetal life is thereby directly attacked and agrees that we are not always prohibited from doing what is lawful in itself though evil consequences may follow which we do not desire. The good effects of our acts are then directly intended and the regretted evil consequences are reluctantly permitted to follow, because we cannot avoid them. The evil thus permitted is said to be indirectly intended. It is not imputed to us, provided four conditions are verified: (a) That we do not wish the evil effects but make all reasonable efforts to avoid them; (b) that the immediate effect be good in itself; (c) that the evil is not made a means to obtain the good effect, for this would be to do evil that good may come of it, a procedure never allowed; (d) that the good effect be as important, at least, as the evil effect. All four conditions may be verified in treating or operating on a woman with child. The death of the child is not intended, every reasonable precaution is taken to save its life. The immediate effect intended, the mother's life, is good. No harm is done the child to save the mother. The saving of the mother's life is in itself as good as the saving of the child's life. Of course, provision must be made for the child's spiritual as well as for its physical life, and if by the treatment or operation in question the child were to be deprived of baptism which it could receive if the operation were not performed, that evil would be greater than the good consequences of the operation. In this case the operation could not be performed. Whenever it is possible to baptize an embryonic child before it expires Christian charity requires that it be done, either before or after delivery, and it may be done by anyone, even though he be not a Christian." The Anglican Church and the Protestant churches generally have no special legislation. In England, there being a State church, established by law and part of the constitution, the law of the land governs the matter, and it is treated by the church authorities in the same manner as to nature and degree as it is treated in common law; spiritually the guilty person is excommunicated until by open penance he is received back "into the church by a judge that hath authority thereunto." (Article xxxiii of the thirty-nine articles of the Book of Common Prayer according to the use of the Church of England.)

The definite pronouncements guiding the Catholic clergy and their knowledge of the questions involved are of enormous value in curbing the evil among those in their charge; the ignorance of the subject on the part of the greater number of other clergymen not of the Roman or Anglican Church is not only appalling but even their laxity of reasoning on the subject is, to say the least, disconcerting from those who should be teachers of morality.

I shall barely touch on these questions, as this is not the field for such a discussion; I can, however, not leave it without defining what should be the tenets to be defended by all moralists. We as biologists must strictly inculcate the dictum that the union of male and female elements, spermatozoon and ovum, constitutes life, and destruction of that life is the murder of a human being, is an offence against the moral law. Based on this it is evident that the work of safeguarding our youth by earlier introduction into true, not fanciful, knowledge of sexual matters; the curtailing of venereal diseases by teaching the public to put aside sham modesty must be strengthened by a more open and frank discusssion of the perniciousness, immorality, and danger of the practice of inducing abortion on the slightest pretext, or even no pretext, criminally, for social reasons. I cannot emphasize this point any better than by quoting from an article by Dr. Inez C. Philbrick, "On the Social Causes of Criminal Abortion." (Medical Record, September 24, 1904, page 489):

"It needs no argument to prove that the church in the ecclesiastical sense that of an institution endowed with discliplinary authority over the acts and beliefs of its adherents has well nigh passed, the Catholic alone, amongst Christian churches, claiming and exercising, to any considerable extent such prerogative. At the best the church stands before the community for moral uplift and organized service; at the worst, an aid to business, an impetus to social preferment, a cloak to cover a multitude of sins. Modern science in a century has overthrown the foundations of past theologies; but, unfortunately, the gain in ethics has not been proportionate to the lopping off of superstitions. In the interregnum till men shall have replaced the outer authority of the church they no longer recognize, by an inner ethic sense, society will miss the fear of hell, the whip 'to haud the wretch in order.' That the Catholic church does exert a considerable deterrent influence on the practice of criminal abortion is ad-

mitted. If the Christian ministry would justify its continuance let it bring to the people the gospel of clean living and fling aside the dry husks of doctrine devoid of soul sustenance. Let it order well its life. The example, unhappily too frequent to be exceptional, of a minister of 'the earth, earthy,' the husband of a pale, worn mother of many living children or of as many destroyed in utero, will efface from the memory much godly precept. Mayhap the true minister to his people will be asked to seek another field of service, but he will have left behind the mite of leaven in the lump."

Let us now turn next to the medical aspects of the subject. To clear the field of ambiguities of terms we will state first that time after conception or before viability does not enter into the question at all, for, as stated above, from the biological standpoint the embryo is "life" from the minute the ovum is impregnated, wherever that event may occur, and a definition of an abortion medically, from any viewpoint, according to Tardieu, means the premature expulsion of a product of conception, independent of all circumstances, age, viability, and even of regular formation. Certainly we must classify various varieties. Unfortunately, due to disease, general and specific, in either or both parents, local disease in the mother or accidental extraneous causes, spontaneous abortion may occur or it may be induced, either legitimately or criminally, and it is to these latter classes we must pay our special attention.

The induction of therapeutic abortion has received the attention of many writers, and in a great measure the unanimity of opinion that the lines must be drawn hard and fast in limiting the indications is comforting. For example, P. Dubois limits induced abortion to cases of extreme deformities; narrowing of the pelvis to 6-8 cm. at the superior strait; tumors which cannot be removed or pushed out of the way; high degree of rhachitis; narrowing or obliteration of the vagina; hemorrhages or uncontrollable vomiting, and certain forms of convulsions, but in all these the measure must be a last resort.

Garrigues cut this down in some ways and widens it in others; his indications are pelvic deformities, serious diseases in the mothers, *e. g.*, tuberculosis, cardiac disease, aneurism, chronic nephritis, carcinoma, and threatened insanity. He requires a formal consultation, a written and signed minute, consent of both the husband and of the patient, all in writing and witnessed. The latest discussion is by Taussig, who divides the indications for therapeutic abortion into: (1) Pathologic conditions directly due to the pregnancy-incarceration of the pregnant uterus, acute hydramnios, hyperemia of the toxic variety; (2) maternal diseases aggravated by pregnancy—heart, kidney, tubercular lesions of the respiratory tract, certain psychic diseases; and (3) marked narrowing of the birth canal where the mother cannot be persuaded to take the alternative of a Cesarian section.

So that unless such conditions can be clearly demonstrated in the patient an induced abortion receives the earmarks of illegality. It is surprising frequently to see how laxly this matter is considered, and the slightest discomfort becomes the excuse in certain classes for the induction of abortion. Among statesmen, moralists, and clinicians its frequency, its effect on the race in numbers, and in quality, and its dire effects as to morbidity have been a source of great alarm. Philbrick (loc. cit.) quotes the special committee appointed by the Michigan Board of Health in 1881, "which, after painstaking inquiry concluded that one-third of all pregnancies ended in criminal abortion; that at least 100,000 criminal abortions occurred in the United States annually, and that yearly 6,000 women, at the lowest estimate, died from the direct effects thereof." A few years ago Doléris published statistics regarding the increase of abortions in France which caused the State authorities great anxiety and induced vigorous measures to be taken to limit criminal abortions. Doléris found in certain of the lower districts of Paris that the number of abortions had doubled, and even trebled, in the years 1897-1905. Rimette, in the figures of the Paris Maternité for these years collected 9,875 pregnancies and 1,437 abortions. Of these latter 627 were spontaneous, 414 complicated, 367 infected and 27 deaths. (Taussig.)

Of course, these figures vary as to race and country, and each observer has his own. In Russia we are told Michaeloff, out of 258,000 births, had the proportion of 1-10. Keyssner had a ratio of 1-5.6. Taussig, from his gynecologic clinic of 600 patients, had found pregnancy in 348, 870 full term and 371 abortions. Thirty-six had been confessedly instrumentally induced and 50 women had disease traceable to the abortions. This made his ratio 1-2.3. This seems very high, and to make sure of the figures for this part of the country I went over the case histories of the Women's Hospital, St. Michael's Hospital, Newark, from 1894 to 1909, with the following results: Two thousand three hundred and twenty-five married women had born 7,387 full-term children, and had had 2,432 abortions, making the ratio of abortions to births as 1 to 3.04. Of the first 1,500 women in whom the ratio was as 1 to 3.16, 426 cases came for gynecological treatment directly traceable to the result of abortions. It is, of course, difficult to get accurate figures, for most women in this matter are conscious or unconscious liars, and there is no doubt that there are many more criminally induced abortions than are tabulated in this list, although we search out this history very accurately whenever possible, as it is often the clue to the etiologic factor in an otherwise dubious case. But how intensely dangerous a field it is we need only show by the figures of Maygrier, who found only 47 per cent. recoveries in 17 cases of criminal abortion operated on within two days after appearance of symptoms, and less than 35 per cent. of successes when operation was delayed to the third day or later.

For the purposes of this paper we need not enter upon the question of the diagnosis of the already established abortions, nor to give the picture such present on inspection of the genitals. Here again all gradations obtain. From the simple wounds in the cervix left by the tenaculum or the more violent abrasions due to the hastily used dilator, to the ruthlessly torn uterine body and the dragging down of the abdominal contents into the vagina, we have seen them all; and still no case is like its mate exactly. It is unnecessary to give case histories here, for we as physicians do not need them to act as deterrents from such acts. But if the laity could see the dire effects of such work occasionally it might be more effectual than many exhortations from the mouths of statesmen, teachers, or preachers. But it is not the immediate effect but rather the long suffering and perhaps permanent morbidity, the induced abortion calls forth even if the patient successfully negotiates the particular criminal interference, which 6 per cent. do not do. The frequency

of the removal of the adnexa, the local and almost irremediable pain, the consequent economic loss due to sickness all are potent arguments from a medical standpoint. (See Report French Obstetrical Society, Paris, Oct. 8-10, 1908.)

But while altruism has been the keynote of medicine at all times, in this question it must not be driven too far, for the law is no respecter of persons, and it behooves us therefore to drop this philanthropic vein and discuss the question as to how the legal end of this subject looks. The definition does not differ in law materially from medicine. "Abortion is defined to be the delivery or expulsion of the human fetus prematurely, or before it is yet capable of sustaining life (Vol. 1, Cyc., page 170). Abortion as a crime, it has been said, is to be found only in modern treatises and in modern statutes, no trace of it being found in the ancient common-law writers (State vs. Cooper, 22 N. J., L. 52; 51 Am. Dec., 248). The history of the evolution of the present statutes is very interesting reading. It was stated in an opinion delivered by Judge Scudder (State vs. Herman W. Gedicke, 43 N. J., L. 86): "It is further objected that there was error in the charge that it was not necessary that the medicine, drug or noxious thing advised to be taken, administered to or prescribed for her should be capable of procuring a miscarriage, because that would be graduating the guilt of the defendant by the success or failure of the attempt, when the statute makes the attempt a crime regardless of the success." The words defining the means to be used were brought into our statutes by the act of March 1, 1849, Pamph. L., p. 199. It was passed to remedy an adjudged defect in our law, that to cause or procure abortion before the child is quick was not a criminal offense at common law or by any statute of our State (State vs. Cooper, 2 Zab., 52). As soon as the question was raised and the doubt suggested the act was passed to punish the offense. The design of the statute was not so much to prevent the procuring of abortions, however offensive these may be to morals and decency, as to guard the health and life of the female against the consequences of such attempts. This law was further extended, March 26, 1872 (Pamph. L., p. 45; Rev., p. 240, 75) to protect the life of the child, also, and inflict the same punishment, in case of its death, as if the mother should die."

The outcome of this was that the perpetrators of the crime ensconced themselves behind the excuse that the operation was necessary for some reason or other. The ruling was then made (Vol. 1, Cyc., p. 188) that the burden of proof rests on the defendant for the purpose of showing that it was performed on the advice of one or more physicians as the case may be. The reason for the rule is while it is necessary for the State to produce some evidence that the abortion was unnecessary to save the life of the mother, the burden of showing that it was advised by a physician to be necessary for that purpose is on the defendant, since from the very nature of the case knowledge of such fact resting exclusively with the defendant could be easily produced by him, though impossible of production by the prosecution (State vs. Meek, 70, Mo. 355; 35 Am. Rep., 27). Also the converse rule holds: Where the performance of an abortion is shown it will be presumed in the absence of evidence to the contrary that it was not necessary to save the mother's life (Vol. 1, Cyc., p. 188). But the question that interests us most of all is the stand that a reputable physician must or should take when brought face to face with an abortion he may suspect or know to have been criminally induced. In 1895 two innocent practitioners were arrested and haled to court, treated with cruel indignity by the powers in force, and though the mistake was proven an egregious blunder it brought them unpleasant notoriety and damage to their reputation, without any chance of redress. The Medical Society of the County of New York requested their counsel, Mr. R. C. Taylor, to advise them what is the status of a physician called in to a suspicious case. He formulated following conclusions: (1) There is no rule or guide; the question is one of good sense. (2) Under common law failure to report a crime suspected was a crime, but the penal code superseded the common law. (3) But failure to report a death under suspicious circumstances to the coroner or police authorities is a misdemeanor and punishable by sentence to prison or fine, or both. (4) No statute makes a physician's report of a case of illness involving criminal malpractice obligatory or a failure so to report punishable. (5) Nevertheless, in such a case it is best practice to call in a consultant to approve the integrity and wisdom of the treatment, and then communicating his suspicions to the coroner, putting the responsibility up to him. (6) This is not modified by his duty of concealing facts becoming known to him for as long as the physician did not idly disseminate suspicions and simply reported them to the authorities he could not be held for libel or slander if his suspicions were proved unfounded. The comments on this report by an editorial in the Medical Record, April 27, 1895, are exceedingly pertinent and will bear repeating in this connection. While agreeing that ordinary humanity bound every physician to attend any patient irrespective of character, still he owes it to himself and his reputation to guard himself against the charge of complicity in any criminality. The common law and the penal code take precedence of the ethics of his profession, and he dare not uphold the code of a class against the statute of a state. "The simple fact is, the law requires that in all doubtful or suspicious cases he must make a report either to the coroner or the Health Department. This is the beginning and the end of the whole matter; he can put what construction he pleases upon the purely professional aspect of the question, but he must conform to the law whether he believes in it or not." Further along the wisdom of Mr. Taylor's advice is criticised and its validity in a test case questioned, "inasmuch as the law contemplates punishing attempts at abortion, either directly or indirectly, by the patient herself or the operator," and the article ends with the recommendation that this could best be regulated by investigation by a medical coroner who could work up a case without exposing innocent physicians to the public or jury in an alleged violation of professional obligation. "The physician cannot, in complying with the letter of the law, afford to wait until his patient is dead before he divides his responsibility with the proper official. Abortion is none the less a crime even if the patient lives; the only difference being that there is but one murder instead of two. In any and every event the physician in attendance should keep his own skirts clear."

While we as physicians, especially as gynecologists, see the frequent results of induced abortions, many of them admittedly self or criminally induced, the law certainly shows as a usual thing no undue activity in ferreting out or punishing the criminal.

Many excuses can be made for this, however. The very fact that the victim is really a conspirator in the crime, and in the case of death robs the prosecution of the most valuable witness; that the law demands proof of pregnancy and determination to interrupt it, whatever the means employed; the difficulty in combating political and social influences that condone and enlist themselves in efforts to nullify the punishment of abortionists, all explain if they do not excuse the infrequency of punishment of such criminal offenders. By the courtesy of Prosecutor Mott of Essex County I have before me a list of the abortion cases considered by the Essex County Court of Quarter Sessions from the April term, 1899, to the December term, 1909. In all, nineteen cases were tried with the following outcome: Five were *nolle prossed* and three were not tried. One of these fled, forfeited the bail, and another turned State's evidence. Of the other eleven five pleaded "non vult," and received penalties involving terms in the penitentiary and fines up to $1,000, and the others were found guilty and condemned from six months to five years in State's prison.

There is still another phase to this question. Not all physicians, while perfectly conscious of their duty in the matter, feel equal to the task of aiding the prosecution in these cases. The unpleasant notoriety, associated with newspaper comments, and the nerve strain in the technical preparation for a trial, and the irritable state of mind induced by the innuendo allowed the defendant's lawyers are not conducive to the growth of any desire to aid the State in a fight against this particular form of crime. While, of course, much of this cannot be altered in the nature of things, and while the defense in such a case brings up the question of expert testimony, there is not a particle of doubt that the greater part of the nerve wear and tear, not to mention the pecuniary loss incidental to court attendance, which is not measured in dollars, but in patients, are all for the most part unnecessary, and tend to make even the law-abiding physician take the chance and wait to see if the patient may not weather the storm successfully, and thus make the report of a suspected crime not an obligation. He knows that it is wrong and illegal; but the fact that he has witnessed the law, even, balked in its judicial vengeance by further legal quibble; that the very law makes his task an exceedingly arduous one, with the added fact that motives are questioned by even intimates and associates, both lay and professional; these all are potent excuses for his hesitancy and will always be so until the law will be strong enough to try such offenders without recourse to appeals to keep them out of jail for an indefinite period and to protect the physician who has been attending the victim of these practices from innuendo and questioning of motives, and not put him in the light of prosecutor or persecutor. The fact remains that when such a case is reported it is investigated with the blare of trumpets and the newspapers know of the matter and draw inferences and make allegations long before there is any foundation for them. Such should not be the case. The evidence should remain secret until the prosecutor brings it to the attention of the grand jury, or at least until an arrest is made. This would remove the most irksome feature in the report of such cases and facilitate the speedy apprehension of most abortionists, and also safeguard the unjustly accused from unmerited notoriety and malicious accusations.

From the foregoing it might well be surmised that our subject to-night deals only with the professional abortionist; or, at least, the abortionist who has come into conflict with the law to his detriment; but in a symposium on this theme in the Chicago Gynecological Society, February 18, 1900, Dr. R. W. Holmes, one of the essayists, pointed out that in addition, two other classes needed attention, apprehension, or warning. First, the young man who is inveigled into committing his first offense in his pressing need of money; secondly, the man who stands fairly well in the community, with a certain clientèle and who largely is engaged in ethical practice, but who relieves his patient in order that he may hold his families. There are too many members of this second class who even may be members of the local, state, or national medical societies. The clandestine work of this class of men is even more reprehensible than that of the out-and-out criminal who takes his chances deliberately, advertises in the daily papers and accepts his punishment when the sword falls perchance. It is the former who, because he has not backbone enough to set the erring matron straight brings about the lamentable condition the statesmen most deplore. He has not even the excuse of pity for the unfortunate or unmarried victim; his is a mercenary motive alone, and nothing can condone such or expiate the crime under those circumstances. But the root of the evil does not lie even with them. Our false education on matters hygienic and physiologic; our laxity in not teaching our youth the questions involved in sexual matters; the low moral tone pervading our modern life, these are to blame even more than the individual evildoer, and until society awakes to its obligations, gives the unborn their rights, and conserves our females against the vampire of abortionism, it will avail but little to fight this battle from any vantage point, be it medicine, theology, or law.

A SOCIOLOGICAL EXPERIMENT.

By G. FRANK LYDSTON, M.D.,

CHICAGO.

PROFESSOR OF GENITOURINARY SURGERY AND SYPHILOLOGY IN THE MEDICAL DEPARTMENT OF THE STATE UNIVERSITY OF ILLINOIS.

Sociologically the treatment and reformation of the inebriate has long been a subject of great interest to me. My opportunities for the personal study and management of such cases, as is true of most men outside of institutional work, have necessarily been moderate. As an "onlooker in Venice," however, I have formed some pretty definite conclusions regarding the inebriety problem. Briefly these are:

1. We have not yet entirely shaken off the fallacious belief that the inebriate is merely immoral, or even criminal, and should be treated in accordance with his deserts. It is not so very long since I heard the physician in charge of a public "home" for inebriates publicly state that "a drunkard should be treated like any other criminal!" This *ipse dixit* elicited great applause from the "moderate" drinkers and teetotallers in the audience.

2. Most of those who have adopted the modern materialistic and logical "disease" theory of inebriety have advanced but little in the matter of its therapy. Homes for inebriates still are merely safe harbors for sobering up and the treatment of delirium tremens, or the drug treatment of chronic inebriety.

3. That the inebriate is a sick man should go without saying. Whether he was a sick man neuropathically or otherwise, hereditarily or acquired, at the time he took his first drink, is beside the point. He now is sick, usually in multifarious ways. His physical fiber is weakened, his will and moral fiber practically nil, and his vital organs in general perverted in both structure and function. Both moral and drug therapists would do well to keep this in mind.

4. No system of treatment can be permanently successful in the majority of long standing cases that does not bring to the fore the man beneath the "habit." Drugs, mechanotherapy, moral suasion, and preaching alike fail here. Emotional or religious reformation does sometimes occur, and drugs have their quota of cures in the hands both of quacks and reputable practitioners, but these cures are rarely permanent—most of them are houses built on the sands. Counter emotions and backsliding from grace are powerful foes of the unstable wills of inebriates who are not cured, but "reformed."

5. The restoration of physical fiber with restored moral balance and will power in its sequential train is the keynote of management of the inebriate. Moral suasion, religion, and suggestion should be regarded as adjuvants.

6. No method of treatment of chronic inebriety is logical that does not involve steady, systematic employment of a physical nature in the open air. Even this is a failure if the environment is not free from temptation; in brief, free from the lure of city life. If there ever is a specific for inebriety, it will be farm sanatoria, backed up by laws which regard the inebriate, not as a criminal, but as a dangerous social element which should be segregated and cured just as a case of contagious disease would be. Who among us has not been confronted with sad cases in which we yearned for legal power to put the patient under seclusion and restraint and thrust a cure upon him? The law takes no cognizance of the drunkard who does not commit statutory crimes. We, therefore, are helpless.

7. The medical profession, reformers, preachers and sociologists alike should concentrate their efforts to secure the enactment of laws which shall (a) protect the family of the inebriate, (b) protect the inebriate from himself, (c) protect society from the depredations and dead loss of the drunkard to the body social.

Some eight years ago I requested Mr. J. W. Gossard of Chicago, one of our most enthusiastic and intelligent slum workers, to procure for me several chronic inebriate subjects upon whom to try the experiment of farm treatment. My instructions were that he should get the "toughest" cases he could find, who were not criminally inclined, and who showed a willingness to be "cured." My friend followed instructions to the letter, and the most exacting could find no fault with his selection from the standpoint of apparent difficulty of cure. The history and management of the two cases submitted will, I am sure, be of great interest to all who are philanthropically or sociologically inclined. Of still greater interest should they be to the physician, within whose province the inebriate sooner or later falls. I submit them with no claim of expertness in the management of inebriety, and with no intent of dogmatism. Nor do I claim that two cases are sufficient to conclusively prove my point. I merely hope to excite interest sufficient to impel others to work along the same lines, and that some of our wealthy men may be inclined to carry out on a larger scale the experiment herein related. The burden of my plea briefly is for:

1. Small colonies of inebriates sequestered on more or less remote farms.

2. Daily systematic, physical, open air labor for the patient.

3. Such drugs and suggestive therapeutics as the exigencies of the case may require. The element of suggestion in drug treatment is of especial importance at the beginning of treatment.

4. Continuance of treatment until such time as the patient's physical vigor, will power, pride, ambition, and confidence in his ability to face a man's world with manhood's strength have been restored.

Case I.—E. S., a man of 50 years of age, of fair education, who had at various times held positions of responsibility. This man had been a confirmed inebriate for about five years, and had degenerated into a levee "bum" and frequenter of the lowest of the levee resorts. This man recently gave me his history more in detail, and stated that he began hard drinking when a boy of fifteen at school, and had practically continued the habit until he fell in my hands. Various attempts to reform him had been made, without success, by different persons. He had merely stopped drinking for a few days at various times. He was placed in my hands for treatment along the lines already outlined, and was a most unpromising case. The only hopeful element in his case was his pathetic statement that he could not stop drinking because he was "continually exposed to the sight and smell of liquor" in his usual haunts and had "no will to resist temptation." This suggested that a change of environment might assist in his cure.

After assuring myself that E. S. really was willing to submit to treatment, I put him upon a small farm, situated some distance from the city, which I used chiefly for the purpose of recreation and rest, instructing the man in charge not to permit him to leave the place without my consent, an arrangement in which the patient readily acquiesced. I informed the patient that, while he was on no account to leave the farm during the intervals of my visits, he could return with me at any time that he might elect. I also mapped out for him various tasks, with due precaution as to possible overwork, arranging the tasks in such a manner as would keep him busy with something or other from early morning until night. For about ten days I gave him small doses of strychnine. Later, I substituted placebos for the strychnine, with explicit instructions as to time and manner of taking the alleged potent remedies. After a few weeks I stopped the placebos, assuring the patient that he was now safe without medication.

Improvement in my patient was rapid and marked. He soon became bronzed and hardy, and was able to do a full day's hard work. At the end of about ninety days he stated that he now was "a man again," and would like to return to Chicago, remarking that he now could face the lure of the city without danger of relapse. I brought my charge to the city, took him to a department store, fitted him out "from top to toe," gave him enough money for his immediate necessities, and sent him forth to begin life's battle anew.

E. S. reported to me weekly, until I was reason-

ably sure of the continuation of his good behavior. He married, some months later, and a short time afterward gave me something of a shock by disappearing for several weeks, after a quarrel with his wife. He turned up, however, safe and sound, and without having relapsed into his old ways. This, it seemed to me, was a pretty severe test of his trustworthiness.

At the end of a year E. S. suddenly ceased to report to me, as he had done at irregular intervals since I pronounced him cured. I had not heard from him for some months and was beginning to lose confidence in my results, when I received a number of Eastern papers containing remarkable lectures on temperance delivered here and there by "Professor E. S." My levee bum had become a noted temperance worker.

E. S. continued his labors in the temperance reform field until about three years ago, when he became ordained as a Methodist clergyman. He since has creditably presided over the destinies of several modest churches, and is still at work in his chosen field.

Case II.—A man 60 years of age, known for obvious reasons to the denizens of the levee as the "Judge," was brought to me by my friend Mr. Gossard immediately after E. S. had completed his course of farm treatment, remarking, "Doctor, if that first case was not tough enough for you, this one will tickle you to death." My second patient was reputed to be a graduate of Dublin University and, it was claimed, had served as a Judge in Dublin. He had at one time been worth considerable in money and property. Because of his advanced age and the duration of his evil habits and associations, the "Judge" was indeed a difficult case. The term "besotted" was particularly applicable to him. His mentality was noticeably obtunded. Physically he was as sluggish as he was mentally.

I followed the same course with the Judge as with E. S., but had much more difficulty in rousing him to the necessity of physical effort. He was positively ambitionless, and markedly showed the effects of deprivation of his accustomed beverage. Under strychnine, however, he finally braced up, and after a few weeks showed interest in his work and began to show a disposition to cooperate with me in my efforts to cure him. At the end of three months the Judge had undergone a physical and mental transformation, and, like E. S., expressed himself as ready for his return to the city.

The Judge was of a type different from E. S. I never have seen him since we parted at the depot on his return to the city. He did not even give me a chance to "outfit" him. I heard from him indirectly, however, from time to time, for some years, and learned that he had not returned to his former life of dissipation, but was a sober, industrious citizen. I finally got out of touch with him altogether, hearing nothing from him until a few weeks ago, when I learned that he, too, was still a credit to the farm treatment and that he had followed in the footsteps of E. S. and become a successful temperance worker—and, more remarkable still, that he also was a clergyman.

As eight years have elapsed since I took my protegés to the farm, I feel pretty confident of their permanent cure. I submit them to the profession, however, merely as a sociological experiment which is suggestive, to say the least.

MULTIPLE AND COMMINUTED FRACTURES OF THE METATARSAL BONES IN A CHILD, WITH SKIAGRAPH.*

By MEDWIN LEALE, M.D.,
NEW YORK.

This is the case of a boy thirteen years old, who, while playing with his comrades, fell from an inclined cable pulley exercising apparatus, falling a distance of about ten feet. He landed on his left foot which was in the position of full extension and adduction, the foot being bent under him, with the toes in plantar flexion, so that the force of the impact and the weight of the body came on the dorsal aspect of the heads of the metatarsal bones. The result as ascertained from the .r-ray was the following:

The first metatarsal presented a longitudinal fracture on its outer aspect beginning just below the

base and extending downward to the middle of the shaft. The second metatarsal showed two distinct fractures, one complete fracture through the middle of the shaft, slightly oblique in direction, the other a complete longitudinal fracture through the head and adjacent portion of the shaft. The third metatarsal showed a complete transverse fracture through the shaft of the bone at the junction of the lower and middle thirds, and comminution of the head and lower third of the shaft.

The case was seen by the author a number of hours after the receipt of the injury, when inspection showed the whole foot and ankle greatly swollen, and there was considerable hemorrhagic extravasation into the soft parts, amounting to a small hematoma over the shafts of the first, second, and third meta-

*Read at a meeting of the Alumni Association of the St. John's Guild Hospitals for Children, November 16, 1910.

tarsals. The skin remained unbroken. On gentle palpation over the heads of the first, second, and third metatarsals pain was markedly increased, but until the swelling had somewhat subsided distinct crepitus could not be made out, owing partly to the extreme tension of the tissues, and also in part to fear that with more vigorous palpation the fragments might be further displaced and become separated by the interposition of some of the soft tissues, which would have interfered with union. The x-ray fully cleared up the details of the injury.

After the swelling was reduced and proper apposition of the fragments secured, the whole foot was placed in a plaster-of-Paris bandage, so applied as to preserve the arch of the foot and its supporting power. The boy made an uneventful recovery, in a little over two months had a perfect functional result, and was playing tennis when I last heard from him.

This case is cited to illustrate the complete functional results which under proper management so often follow multiple and comminuted fractures in children, particularly provided too much manipulation has not further displaced the fragments, and nature has been given every chance.

A few facts in regard to the development of the metatarsal bones on which stress is not always laid are well illustrated in this skiagraph.

The primary center for the first metatarsal bone, appearing about the third month of fetal life, comprises the head and shaft. The secondary center, representing the base of the bone, appears about the second or third year of life, and this fuses with the shaft about eighteen. The primary centers of the second, third, fourth, and fifth metatarsals furnish the bases and shafts of the bones, the heads on the other hand being developed from secondary centers which appear from two to four years after birth, fusion with the shaft being usually complete by the eighteenth year. The first metatarsal bone, therefore, in its mode of development resembles the phalanges. This mode of ossification which obtains in the metatarsus closely resembles that which takes place in the metacarpus.

852 Lexington Avenue.

SUDDEN DEATH FOLLOWING SPINAL PUNCTURE FOR DIAGNOSIS.*

By EDWARD M. COLIE, M.D.,

NEW YORK.

In the case of H. O., age 16 months, there was no family history of tuberculosis nor of syphilis. At the time of the onset of this attack an older brother was suffering from an attack of intestinal indigestion. Save for attacks of bronchitis when three weeks and one year old the child had been well up to the onset of the final illness. The child was nursed fairly successfully up to the age of two months, when, for reasons not given, it was placed upon a feeding of arrow-root and whole milk in equal parts. After the ninth month it was fed whole milk together with soft solids. For three months the child had had running ears, the antecedent history of which is not known, except that they were not consequent upon acute febrile disease.

On or about June 1, 1910, without other symptoms, the child began to vomit. The diet at this time was milk, soft solids having been discontinued with the onset of the hot weather. Several physicians saw the child at this time and it was treated by diet and catharsis. No improvement followed, so the mother was persuaded to enter Sea Side Hospital with the child. The following is the course after the child came under observation there:

Admitted July 15. July 16 the mother called attention to the fact that the child had vomited several times. July 19, temperature 100.8°, patient was fretful but appeared to be hungry. July 24, the child vomited at frequent intervals during the day, and the highest recorded temperature was 101°. July 25. As the patient continued to vomit during the night he was transferred to the Lewis Pavilion, where the stomach was washed out at 10.30 and no food given for six hours. At 12.30 and at 4.30 P.M. the child vomited clear fluid. During the evening he appeared to be in pain, cried continuously, and later in the night appeared to be apathetic. Upon admission to the ward a cursory examination showed little of interest, as the pupils and the reflexes were not examined. July 26, at 10 A.M., there was a general convulsion. At some time between this and afternoon rounds the child became comatose. At rounds at 3 P.M. the child was presented as a moribund case of gastroenteric infection. The little one was in profound coma. The reflexes were entirely absent. There was very slight rigidity of the neck. Kernig's sign was incomplete. The pupils were sluggish, and the right was moderately widely dilated. The pulse was rather slow for so sick a child, not over 120.

As I thought that the case was clearly one of cerebral compression, most probably one of tuberculous meningitis with onset characterized by predominance of gastroenteric symptoms, a not uncommon form of beginning in this disease, I asked the resident physician to do a lumbar puncture at once. This he did without difficulty, observing the usual technique and choosing the usual site for the operation. About 5 c.c. of clear fluid flowed under increased pressure, then the flow became slow. As I was anxious to get sufficient of it for purposes of diagnosis we waited for 10 c.c. then withdrew the needle. At the end of the few minutes that we waited for this to happen the child had slightly roused and was able to cry feebly once or twice.

That was the last patient that we saw in the Lewis. We walked over to Ward 5 and had just started upon the examination of a patient there when the nurse sent for us, saying that the child was in very bad shape. Arrived at the bedside we found rigidity general and absolute, the child black and asphyxiated, making no respiratory movements of any sort; jaws set, intercostal muscles spastic, diaphragm apparently not moving, the heart beating as during the previous part of the day. In a few moments, as the asphyxia deepened, all of the spasm relaxed, and the breathing was taken up. During the remaining portion of an hour, until the child died, the picture was one of alternate phases; general intense spasm until extreme asphyxia was reached when the phase of relaxation would set in and respiration would be resumed. The respiration during this time was of the Cheyne-Stokes type. The heart rate increased steadily until the heart stopped during one of the convulsions.

Autopsy on July 27. Upon removal of the skull cap, the dura mater was found distended. Upon incision a large quantity of purulent fluid escaped.

*Read at a meeting of the St. John's Guild Alumni Association, November 16, 1910.

The dura stripped readily both from the brain and from the bones, except where attached at the base and over the petrous portions of the temporal bones. There were no discovered perforations, adhesions, or other indications of the avenue of infection of the meninges. The frontal sinuses were normal. Both middle ears contained seropus. The spinal fluid was clear. The brain was at once hardened in 5 per cent. formulin solution and sectioned upon August 5. At that time there was found, occupying the anterior pole of the left frontal lobe, an almost spherical thick walled cavity with a diameter of 5 cm. It contained thick pus. This sac was ruptured either during life or during the manipulations necessary to the removal of the brain. The whole left hemisphere was soft and mushy, in sharp contrast with the right hemisphere which appeared to be normal.

The chief interest, I take it, of this case centers about the mechanism of death. I do not think that there can be any reasonable doubt that the immediate cause or occasion of the death was the spinal puncture. The interval of time (five minutes at the very greatest estimate) between the puncture and the onset of the terminal phenomena is too short to permit of other views. Ten c.c. was a small amount of fluid, yet it is readily conceivable that just that 10 c.c. in the small spinal canal was sufficient to maintain a working balance with the greatly increased intracranial pressure. That the intracranial pressure was great was established at the autopsy.[5] That there was not in this case a free communication between the cerebral and the spinal meningeal canals, is, I think, amply established by two facts: first, the fluid in the spinal canal was not appreciably increased in quantity, although under slightly increased pressure; secondly, the character of the two fluids was radically different; that of the spinal canal was normal in appearance, that of the cerebral cavity was pus. Again, the time that the child lived after the puncture was too short for the development of pus. The pus was there at the time. With a high degree of intracranial pressure and a free drainage through the spinal canal it is relatively safe to do a decompression by means of lumbar puncture.[1], [2]. If, however, this free drainage is interrupted then this procedure is fraught with the risk of sudden death due to foraminal hernia.[3] Foraminal hernia results in the anemia asphyxiation of the medulla, with the consequent arrest of the function of respiration.[3] That death is not always instantaneous in these cases is to be accounted for in this wise: the pressure relieved below, the cerebral pressure crowds the medulla against the sides of the foramen magnum and down into it, causing an acute and complete cessation of the circulation in that portion of the brain. This anemia continues until the accumulated carbon dioxide in the blood raises the arterial tension to a point where the circulation within the medulla is reestablished. Then respiration is resumed and the carbon-dioxide content of the blood is reduced; with the occurrence of this there is a fall in the blood pressure until the circulation in the medulla is again throttled. Eventually the heart dilates in one of the phases of apnea and the process terminates.[4]

This explanation of the unfortunate train of symptoms which I have recited in connection with this case has at least the virtue of scientific plausibility. I have sought diligently for other satisfactory explanations and have not found them. I trust that discussion this evening will bring to light other points of view and throw more light upon this, to me, very interesting case.

SHORT TALKS WITH MY STUDENTS AND OTHERS: BEING RANDOM SUGGESTIONS FOR THE YOUNGER PRACTITIONERS.*

By ROBERT H. M. DAWBARN, M.D.,

NEW YORK.

Wallaby Tendon.—The late Dr. Nicholas Senn, writing from Australia during one of his trips around the world, said that it is a source of amusement to the Australian surgeons that we call by the name of "kangaroo tendon" a certain strong and absorbable material for suturing or ligating, and far more used in America than in Australia. The tail tendons of the kangaroo are much too coarse to be capable of being shredded and employed in this way. What we really use—when the material has honestly come from far Australia—is fiber from the tail tendon of the very long-tailed, rat-like creature called the Wallaby, or rat-kangaroo. Why not call it by its proper name? And yet, upon reflection, is he not a public benefactor who adds a smile to the gaiety of nations?—even for a moment lessening thereby the somberness of life! As a matter of altruism, then, suppose we continue to say "kangaroo tendon"; thus rendering a trifle happier our Australian brethren!

Who Should Wear Rubber Gloves?—(1) For your own protection never operate ungloved upon strangers. The ordinary estimate is that ten per cent. of the population of cities, alike here and in Europe, are either now syphilitic or have been so. (2) For the patient's protection the large majority of operators should wear rubber gloves; for, although sterile of hands upon taking up the knife, being in a warm room, or getting into a "tight corner," will soon bring the sweat, and it will be full of microbes, some of them pathogenic. A minority of surgeons perspire as freely, but it is sterile. A still smaller number never sweat—even in a Turkish bath. These two classes last-named can obtain satisfactory asepsis even with naked hand work. But they, even far more than those who operate gloved, never should touch pus. It sends a cold chill up my spine to see a surgeon do this! Read Lawson Tait upon the almost unbelievable tenacity of life for evil in the case of certain kinds of pus. Once soaked into the skin, they invite themselves to abide long—days or weeks—therein, ignoring all scrubbing and antiseptics. It reminds one somewhat of the kind of visit described in the biographies of the Rev. Dr. Watts. Asked by a certain kindly baronet to stay at his very comfortable home during a convalescence, the visit did not end with recovered health. It lasted until Dr. Watts' death, twenty and more years later!

A Few "Wrinkles" as to Large Rubber Tubing.

*See Medical Record, March 4, 1911.

—To procure the large tube of pure gum rubber needed wherever a cutting operation is to be performed upon a limb—in order to do bloodless work—go to the nearest garage, and buy, for a fraction of the expense of an equally heavy and strong tube elsewhere, a badly torn inner tube of a runabout automobile. The smallest size is best, and about two-thirds of its length is abundant, even for hip-joint work. Regarding the protection of rubber goods, remember that ointments, oil or vaseline, also collodion, benzine, ether, chloroform, and alcohol, all attack it. Neither should you handle surgeon's adhesive plaster with rubber-gloved hands. Pure gum—absolutely so—will not be injured by boiling. However, our gloves are seldom indeed made of really pure rubber—at least when the maker has been established in business for some time; and they should therefore not be boiled longer than five minutes. It is indifferent whether or not borax or baking or washing soda is in the water, meanwhile. Each of these chemicals, at least one per cent (teaspoonful to the pint of water is roughly correct as being one per cent. of anything) added to the water in which the instruments are to be boiled prevents rusting. The rubber gloves and tubing may be boiled in the same solution, if desired. With some implement hold the towel-wrapped gloves under water, which must be boiling upon entrance to enable us to time accurately; and avoid pressing them down upon the extremely hot bottom of the vessel, for otherwise the rubber will be so affected as readily to tear. One remaining important point as to the durability of your tubing aforesaid: Quiescence is with it, as with a business man of active life who has retired, the beginning of decay, and death soon follows. If a bicycle tire is at the onset of winter pumped up hard, and kept so, in the spring it will still be found in good condition. But if allowed to become flat—if its component particles are under no tension—it soon begins to crystallize, to become hard, to lose elasticity, in a word, to die. I keep my big tubing in the overcoat closet. It is clamped at both ends. By one it hangs to a coat hook; at the lower end is hung, by the second clamp, a flatiron. It is impossible for me to remove or replace an overcoat without jolting the tube, so that it is made to spring up and down a few times, thus setting its molecules into vigorous vibration. The unceasing stretching due to the pull from the rather heavy weight, again, never gives opportunity for the absolute rest and quiescence so quickly fatal. I have had for ten years such a tube so treated, and, of course, boiled many times, and often stretched by usage. It seems to-day as strong as when purchased.

The Surgeon's Enemy—the Skin.—Or, rather, our enemies are its permanent residents, still at home in plentiful numbers after all efforts to the contrary have been made; namely, a host of more or less harmless microbes. Occasionally, however, less rather than more—or certain kinds of them—especially when their home surrounds and also constitutes the edge of our wound. At times, then, and particularly just before we are to use the knife, hardly any question has a more real and pressing importance than—How can we most effectively remove the uppermost cuticular layers with least insult to the deepest and to the cutis vera and their denizens? The writer never permits a brush to be used for this purpose, unless it be soft to the last degree, for it is apt to scratch abrasions which invite trouble—turning peaceable microbic tenants into militant nihilists. More effective than the brush, and also harmless—indeed, better even than scrubbing with gauze compresses the soapy skin—is the use for this purpose of a handful of ordinary toilet paper. I do not know why; but anybody can very quickly convince himself of the truth of this claim.

Ultra-Rigid Asepsis Among Teachers.—As teachers of aseptic surgery it behooves us to carry its practice to the last extreme of rigor; even to a degree perhaps wholly unnecessary. A great surgeon of this city now dead, who was also a professor of surgery, used to laugh at the modern avoidance of knives with cross-hatching upon the handles, and similar crevices upon other tools, capable of catching and retaining infective material. Said he, "They are boiled before being used; any microbes must be dead!" But we should avoid even the appearance of evil; and it is undesirable to introduce even sterile dirt—even dead microbes—into our wounds. At my clinics in the City Hospital, during all aseptic operations an experienced interne, called the "Censor of Asepsis," stands upon a stool and closely watches every one in the room—professor, assistants, students, nurses—and everything that is done. In case anyone makes the slightest break in the "chain of asepsis" it is instantly reported by the censor. Theoretically, the assistants or the bystanders commit all blunders, if any. Practically, the operator has most cause to scratch his head! If I chance to be the offender I thank the censor doubly. As a special protection against students, who may otherwise, and perhaps unobserved, touch something which should be sterile, upon entering the operating room, they all don aseptic long gowns, gathered at the neck and dropping to the feet, but *without sleeves*. These resemble a giantess' underskirt. Perhaps these special precautions are unnecessary, but we as teachers will do well to remember a little story, bearing upon this matter of possible overcarefulness: A young clergyman is about to deliver his first sermon. Beside him in the vestry stands a very old and experienced orthodox minister, giving him a few last words of advice before letting him ascend the pulpit. "And in this matter of damnation, now," quoth he, "never, never dilute it in your sermons. Your congregations are sure to do that for you!"

Egg-Membrane Grafting.—In skin grafting why are there such conflicting and contradictory reports as to the value of employing the inner skin of a very fresh egg? It is because of two blunders often made, either of which ruins any chances of success. (1) Place upon the wound (first made aseptic and deprived of its granulations exactly as when Thiersh technique is used) that surface of the egg membrane which normally lies deepest in the egg. The other side, *i.e.* that which lies in contact with the shell, alone has the epithelial cells which we need for cuticle formation. (2) Use an egg from a hen—never from a pullet. The latter does not contain the principle of life (whatever that is). Apropos, remember this experiment of Lawson Tait, often verified by others: A hen's egg and a pullet's egg, laid the same hour, are placed side by side in the same atmospheric conditions. The microbes in the dust of the air, entering the myriad pores of the shells, attack the moist membrane beneath. The hen's egg is able to resist them successfully for a long time; the pullet's egg undergoes decay far sooner—for the reason named heretofore.

Shoulder Tenderness.—One of the main causes

of persistent tenderness near the shoulder joint is bursitis of the exceptionally large bursa beneath the deltoid muscle and just at the edge of the acromion process, anteriorly and externally therefrom. A blow upon the shoulder readily causes this disease; sometimes it is present without any history of traumatism; and mistaken diagnoses, including even supposed arthritis of the shoulder-joint itself, are common. This bursitis can be excluded by a test almost pathognomonic—one which the author has written upon heretofore and long ago (in the Boston *Medical and Surgical Journal*), namely, that when the arm is abducted to a right-angle with the body this bursa slips up beneath the acromion, and hence can no longer be pressed upon. The instant disappearance of tenderness while in this posture and its prompt reappearance as soon as the arm is allowed to drop by the side constitute the sign in question.

Upon Gratitude Toward Doctors.—(Brief essay, lest the title evanesce before *finis* can be written.) Gratitude, like alcohol, is a heart stimulant; it is, however, very volatile; in this again resembling alcohol. Alas! "Too like the lightning, which doth cease to be ere one can say it lightens." Therefore, brother, present your honest claim for professional work while yet the first and final echoes of gratitude—already a thing of the past—linger in the patient's memory. (Three metaphors in as many sentences; yet, none the less, unmixed truth!) At least, we can always find gratitude in the dictionary. Also in the use of the formula "G. P." (Grateful Patient)—well understood by all in the profession. There is here, however, an implied but deceptive familiarity. Surely too flippant a way of characterizing a creature more rare than a day in June! Can it be that in England he is rarer still?

At least this combination of initials has no such meaning there; but according to Conan Doyle—himself a doctor—they stand for the physician, not the patient! That is, in England "G. P." means General Practitioner. As a rule, that is. But upon both sides of the Atlantic it is sometimes used—chiefly among hospital men—to characterize a certain disease of the brain. Should a doctor be himself its victim one might readily make the diagnosis, were the patient with joyous mien and fibrillary tongue-twitchings to offer an unasked loan or gift of a few thousands, upon the ground that by depletion it would help to cure an abnormal plethora of his bank account. That his patients had one and all experienced practical religion; hence the need to relieve his bank from the sudden strain or bulging consequent upon and evidencing their gratitude. Here no doubt could exist as to the trouble; "G. P." (General Paresis) would be its dread name!

Who Loves Anatomy?—Don't all speak at once! In studying this most interesting of subjects it doubles the joy, also the ease of memorizing, to look up the meaning—the derivation—of all the terms encountered peculiar to the human body. Instead, most men memorize them as a parrot would, without the least thought of their etymology.

It will assuredly pay any doctor, whether prospective or present, to learn to draw with fair accuracy the joints of the limbs, the bone-ends both separately and then articulated, from in front, from behind, from the sides; doing this either by aid of a skeleton or illustrations. I advise this not alone for examination-purposes (although it is one of the best because most abiding of helps to the memory), but still more for purposes of self-protection later on, as a practitioner, upon encountering possible dislocation, or impacted fracture involving a joint, or both at once. If one can see the normal joint in his mind's eye he is incapable of the awful diagnoses sometimes perpetrated otherwise. It does seem to me that not even mathematics presents so extreme an example as does the undergraduate study of anatomy regarding the value of the personal equation in selecting the professor. In mercy to its classes a faculty should give more thought to a wise choice herein than any other branch deserves.

At the one extreme I would place such a teacher as Dr. Corydon L. Ford, gone, lo, these many years, where good anatomists go! It was while struggling with the names of the bones of the human skeleton that I once heard him make a remark which, however casual, burned itself into my memory. He said that he had never as yet during the thirty-odd years of his professorship in anatomy delivered a lecture without study beforehand to refresh his recollection of little details. Mingled emotions! Should I feel more dismayed at the obvious hopelessness of ever Knowing It All, thus revealed, or relieved at the thought that he, too, who had been supposed by us all to know anatomy backwards and sideways, as well as forward, was after all a student still, and hence to some degree in the same fix as ourselves! For a while I was a prosector under this great man—a generation and more ago. I recollect the eagerness with which the students raced to get good seats at his lectures. I have seen him start at the skin of the armpit, and in a single hour, during which he held their absorbed interest by his words, he made a beautiful dissection showing the brachial plexus and the axillary vessels. At the opposite extreme I should place a certain gentleman occupying that chair, at the present time, in a different college. His students hate anatomy with an abiding, an undying hatred. He even has the gift of making the blood a dry subject!

The Prime Rule of Plastic Surgery.—Plastic surgery occupies no small part of the operative field. In it the first law—indeed, the rule of rules—is never to attempt to unite two unwilling edges or surfaces; for your sutures being under tension, will assuredly cut out. In surgery, as in matrimony, an unwilling union is apt to be followed by divorce!

Never Rub the Limbs Downhill!—More often than the other way one sees the laity doing this. They often seem to regard a disease—rheumatism, let us say—as a distinct entity which they are endeavoring to drive out of the patient; whereas rubbing upward, they think, might send it into the body, thus fixing it deeper. Curiously, even trained nurses rarely seem to know just why they must never rub the limbs centrifugally. And yet their primary instruction in anatomy should remind them of the delicate valves, in pairs, every few inches along the veins. Vigorous massage in the wrong direction is unquestionably, by tearing these valves, a common cause of varicose veins later on in life. It is usually easy to demonstrate upon the veins under the thin skin of the back of the hand the existence and competence of such valves. Simply press a long vein below, and strip it upwards from this point with the finger meanwhile. Such a demonstration to the eye of the reason for the rule is never forgotten; words alone may well be.

DIGESTION OF VEGETABLES.

EVER since Beaumont's pioneer researches on human digestion, the state of our knowledge of the manner in which the digestive fluids act upon the coarser vegetables has been far from satisfactory. It will be remembered that Beaumont's observations appeared to show that all classes of food, vegetables included, were digested in the stomach alone. To-day we know that certain vegetables may not be attacked at all by the digestive fluids.

Adolf Schmidt, at a very recent meeting of a Berlin medical society (*Berliner klinische Wochenschrift*, February 20, p. 360), considers this subject very fully. The unknown element which stands in the way of the digestion and utilization of vegetables is the varying proportion of cellulose, plus the individual's personal equation—for it is universally admitted that some subjects are much more able to dispose of cellulose than are others. The digestive enzymes act but feebly on vegetables. If an hydrolysis of cellulose occurs at all pentoses should be formed. Contrary to older views, the author asserts that intestinal bacteria do not cause fermentation of the cellulose in the body, although this phenomenon occurs *in vitro*.

Mastication, the solvent action of the gastric and pancreatic juices through the acid and alkali content respectively, and a faint proteolytic action on the proteid content of the vegetables all aid in the production of a chemical comminution or suspension. Thorough cooking naturally aids greatly in securing this desideratum, especially cooking in weakly acid or alkaline solutions. Individuals with chronic constipation appear to be able to utilize vegetables better than those with daily evacuations, on account of the more prolonged sojourn of the food in the intestines. On the other hand individuals who can readily utilize all foods must necessarily be constipated as a result. In hyperchlorhydria it is claimed that vegetables are utilized to a greater extent than under normal conditions. It is difficult to demonstrate the presence of cellulose, by chemical tests, although it is made up of hemicellulose and other substances identifiable with the microscope. Schmidt deals concretely with the least nutritive vegetables, such as radishes, certain kinds of turnips, and so-called edible fungi, which in addition to cellulose contain chitin, the latter further antagonizing the utilizability. But his comments apply in some degree to all vegetables.

Nowhere does he mention the action of the diastasic enzymes on the starch of the vegetables, although he states distinctly that the pancreatic ferments do not attack the latter. We are left in doubt as to whether the carbohydrate content, usually comprising both starch and cellulose, is richer in the latter than is commonly taught, or whether, as is usually held, the cellulose merely protects the starch from the action of the digestive diastases. Any true nutritive value must necessarily come from the contained starch.

It is of interest to note that Klemperer, who discussed Schmidt's paper, expressed the opinion that the natural place for the digestion of vegetables is the mouth, thus voicing the opinion of the American layman, Fletcher. Hence properly prepared vegetables, subjected to prolonged mastication in the midst of the alkaline saliva, might be made to yield up their starch, which would then be changed by the salivary diastase into maltose and dextrose. Such a test could readily be made after prolonged buccal treatment of, say, mashed turnips. There is little doubt that starch would soon be in evidence, chemically, yet such a test would be only qualitative, and would give but an imperfect idea of utilization.

THE STUDY OF CARDIAC HYPERTROPHY.

THERE are many problems in the normal and pathological physiology of the cardiovascular apparatus that are being solved by the recently employed methods of the artificial production of valvular lesions in the lower animals. With the aid of one of these methods, Hugh A. Stewart, reporting his results in the *Journal of Experimental Medicine*, February 1, 1911, has sought to determine, first, the development of the reactive processes known as hypertrophy, in point of view of time after the establishment of a condition favorable to its onset; second, the question of cohypertrophy; and, third, the relation which the altered muscle bears to the normal. By means of the valvulotome devised by MacCallum, Stewart produced aortic insufficiency in dogs, a procedure that can be carried out with ease and certainty. The instrument is passed, under aseptic precautions, down the left carotid artery until the point reaches the sinus of Valsalva which lies between the posterior aortic cusp and the anterior mitral segment. It is now passed through the base of the cusp, the cutting edge turned toward the lumen of the aorta, and, on withdrawing it, the cusp is completely divided in two. The lesion is accompanied immediately by the development of the so-called collapsing pulse and a diastolic murmur. The subsequent development of hypertrophy was determined by the use of proportional weights; namely, the comparison of the proportional weight of the heart to the body weight in the normal animal and in the animal in which an aortic lesion had been produced.

This investigation brought out a number of important facts. It was found that (1) hypertrophy induced by the production of aortic insufficiency involves all the chambers of the heart. The greatest absolute increase in weights is in the left ventricle.

The remaining segments, arranged in the order of decreasing increments, are septum, right ventricle, and auricles. The greatest relative increase is also in the left ventricle, but the auricles show a relative hypertrophy greater than that of the septum or right ventricle. (2) The cohypertrophy of the auricle is not due to an altered venous pressure, but results from an increased force of auricular systole. (3) The heart shows an increase in weight within one week after the production of aortic insufficiency. The increase in weight is due only in part to an increased water content.

As regards the question of auricular hypertrophy, Stewart notes that one cannot at the present time offer an explanation of the physiological mechanism whereby the auricles increase the force of the contractions in sympathy with those of the left ventricle. It is stated that this subject is at present under investigation and the results will be published shortly. So far as his experiments have gone, this investigator has obtained strong presumptive evidence that there exists an intracardiac reflex which maintains a coordination in the force of systolic contraction between the chambers of the heart.

GASTRIC FEVER.

One of the mysteries of the evolution of our knowledge of fevers relates to the nosological position of certain relatively mild types of fever, practically obsolete to-day, which tended to attack children by preference. Two of these were respectively "gastric" and "slow" fever. The former ran an acute and severe course while the latter lasted for weeks and was almost devoid of local symptoms. Practitioners who received their diplomas two generations ago regarded these affections as clean cut, although thermometry was practically unknown. The slow continued fever naturally suggests the benign typhoid of young children, but seems to have had, under that precise form, no mortality worth mentioning. To-day it is never mentioned by name, nor is there any syndrome known to resemble it.

It is otherwise with gastric fever, which is an affection suggesting strongly the gastroenteric type of influenza, save that it is a disease rather of warm than of cold weather, and has otherwise a different incidence from grip. In the *Münchener medizinische Wochenschrift* for February 7. Scheglmann states that the gastric fever of old authors still appears in out-of-the-way rural localities. It appears in quasiepidemics, but is not known to be contagious. He studied a group of 140 patients, made up largely of strong, young farm laborers. The visitation occurred at harvest time. As a rule there were no prodromes. The disease began violently with a chill, followed by high fever and prostration. Unbearable headache, nearly always frontal, soon appeared. There was complete anorexia, often associated with vomiting and epigastric pain and tenderness. The limbs were also the seat of severe pains. The tongue was heavily coated. Tympanites and diarrhea were the rule and nosebleed was common. The viscera otherwise presented nothing characteristic, save the gastric or gastroenteric symptoms. The disease ran a brief course, seldom lasting over fourteen days. Actual mortality from the disease was in some doubt. Two of the 140 patients died, but autopsies were not obtained. The apparent causes of death were heart failure (in an elderly patient) and perforative peritonitis. The treatment used was symptomatic. The subject of differential diagnosis is of chief importance. Influenza was first excluded (by no means an easy task); next came typhoid fever, including paratyphoid, and both were readily excluded by the serological (agglutinating) tests. Meningitis was excluded without difficulty. The old writers could suggest no specific cause for gastric fever as they knew it. The author is inclined to attribute it to some grain fungus, which, however, probably serves only as an intermediary for a bacillus. A single preparation from the stools sent to Munich contained only a microorganism not unlike the paratyphus B., but no actual diagnosis was made.

DEFICIENCY OF CALCIUM SALTS IN TYPHOID FEVER AND DYSENTERY.

Calcium salts are a necessity if a person's physical condition is to be kept up to its proper standard. The lack of food containing these salts in suitable proportions results in a lowering of the health generally and inadequate resistance against disease. Dr. G. Arbour Stephens writes in the *Hospital*, February 4, emphasizing the need of food of lime-bearing value for troops on active service and points to the fact that a deficiency of lime salts does predispose to disease as evidenced by the large number of intestinal troubles that arise in rickety children. Soldiers, as he remarks, are not exempt from the calcium law, drawn as they usually are from the poorer classes, and when on active service, under onerous conditions they have to perform their duties on food deficient in calcium salts, it is no matter for surprise that they suffer from intestinal troubles of an inflammatory nature, and thus help to swell the number of enteric and dysenteric patients.

The dietary of the soldier, at any rate, in the British army is wofully lacking in lime salts. Of all the articles of diet with which they are supplied none contains more than 5 to 7 per cent. of lime salts. Stephens asks whether there is no way out of this difficulty. Of course, troops on active service cannot expect to be provided with fresh milk and eggs, but he suggests that the lime salts in those foods can be substituted by a supply of tablets of calcium lactate, which, together with a quantity of capsules of calcium permanganate, should materially diminish the prevalence of disease in the time of war. Stephens, moreover, states that he has tested the value of calcium lactate tablets on troops in a marching competition with excellent results. In a district, too, in which the supply of water is polluted and where climatic and other conditions are productive of great thirst he recommends that with each draught of water there should be taken one or two capsules of calcium permanganate. By this procedure the risk of infection

would be greatly diminished. The drug taken in this form is not objectionable in taste and it acts in a fresh condition on that part which requires it most, the intestinal mucous membrane. It is certainly true that the diet of the soldier in any army on active service is deficient in calcium salts, for the food of soldiers under such conditions does not vary much in different armies. True it is also that a deficiency of calcium salts in food is calculated to predispose to disease, and, perhaps, especially to enteric fever and dysentery. Therefore, if the plan proposed by Stephens is feasible and effective, there would seem to be every reason for army authorities to look into the question of adopting it.

Modern Sanitation.

At the fourth annual meeting of the Association of Life Insurance Presidents held in Chicago on December 9 and 10, 1910, a paper on modern sanitation was presented by Dr. Alvah H. Doty. The paper contained many points of interest, but perhaps one of its main objects was to draw attention to the fallacy of the belief held up to a comparatively recent date by most sanitarians and still by many, that infectious diseases are frequenty transmitted by fomites. This belief though long in dying has, Doty says, gradually but surely given place to the view that such diseases are usually conveyed directly from one person to another, or by food and drink, as in cholera or typhoid fever, while within the past few years conclusive proof has been obtained that insects constitute a potent factor in the transmission of infection. Reference should also be made to the menace of the human carrier of disease. The speaker maintained that our knowledge of infectious diseases had so greatly advanced that now, with proper isolation and scientific disinfection, whenever required, every outbreak of infectious disease could be brought under control and there was therefore little or no fear, in civilized countries, of any great loss of life such as has occurred in the past and occurs at intervals at the present time in certain parts of the Far East. If, too, as Doty pointed out, proper sanitary regulations could be enforced in those sections which are regarded as the home of bubonic plague and cholera, such diseases would become an unimportant factor as a menace to the public health or would disappear altogether. Again the clothing of well persons is very seldom a medium for the conveyance of disease, nor does Doty hold the view that paper money, however filthy and offensive it may be, is a means of transmitting infectious complaints. The public in his opinion is too liable to become hysterical regarding personal infection and many things are done which to the practical sanitarian are not only illogical but absurd.

Statistics of Tuberculosis.

Writing in *Assurance*, December, 1910, Mr. Lawrence Irwell of Buffalo makes a vigorous criticism of Professor Fisher's paper, "The Costs of Tuberculosis in the United States and Their Reduction." Irwell's paper is somewhat elaborate and it would be impossible to review it carefully within the limits of a brief article. The main contention, however, is that the statistics collected are not sufficiently accurate to be of any real value, and he quotes largely from English statistics, which he says are accurate or, at any rate, fairly so, to disprove the validity of Fisher's assertions. English statistics seem to show that the decrease of mortality from tuberculosis has been slight during the past twenty-six years or so, and Irwell quotes from a letter to himself from the statistical superintendent of the English Registrar-General's office in support of this view. The quotation is as follows, "The diagram facing page C of the annual report for 1908 does not indicate any very marked change in the rate of decline of mortality from tuberculous disease since 1884." Therefore, Irwell argues that, if in England, where statistics are more or less reliable, mortality from tuberculosis has only slightly diminished, it is not likely that in this country, in which loose methods prevail, "any marked change" has occurred. Irwell believes that statistics here which appear to show that the reduction of the mortality from consumption has been immense are absolutely fallacious. The decrease of mortality from tuberculosis is probably not commensurate with the strenuous efforts which have been put forth to achieve this object. However, it would be quite out of place to decry the statistics brought forward by Fisher without making a very careful study of the matter. It is well that the question should be freely ventilated, for it is certainly in the interests of every one concerned that the true facts should be known.

Typhoid Fever and Water Storage.

Some valuable investigations have been undertaken recently in London with regard to the persistency of typhoid fever germs in water, a report of which appears in the *Times*, February 6. The London Metropolitan Water Board has just issued a report on research work by Dr. A. C. Houston, which deals with the vitality of typhoid fever bacilli in stored water and with that of "cultivated" as opposed to "uncultivated" bacilli. The former, of course, were artificial cultures while the latter were obtained from a "typhoid carrier." Bacilli from a laboratory and bacilli from a carrier were added in similar proportions to samples of river water in a carefully conducted and protracted series of experiments with the general result that both varieties alike were proved to be incapable of sustaining an independent existence during storage and perished within definite limitations of time. Houston, therefore, concluded that "even a week's storage of raw river water is an enormous protection and that more than a month's storage is an absolute protection against the typhoid bacillus," and he added that it is in the power of those in authority by adequate storage to render supplies drawn from rivers perfectly safe, however much polluted they may have been originally.

Pseudoleukemia Treated by 606.

Wolff reported to the Breslau Surgical Society (*Berliner klinische Wochenschrift*, February 6) a remarkable cure of the following condition in a boy aged six years: the earliest diagnosis was tuberculous lymphoma of the neck. The glands were extirpated, whereupon fever developed with rapid enlargement of the supraclavicular, axillary, and inguinal glands. The liver and spleen also became enlarged, ascites followed, and the patient became cachetic. The diagnosis clinically and from examination of blood and tumor sections was pseudoleukemia. Four injections of 606 were given at two weeks' intervals. As a result the splenic tumor

vanished first, then the ascites, and finally the glandular swellings and cachexia. Recovery was almost absolute, only a few enlarged glands persisting. The result recalled those obtained years ago by Köbner in cervical lymphadenoma by injecting Fowler's solution directly into the glands. It is to be regarded as due to the arsenic in the molecule of salvarsan. The latter was injected between the shoulder blades.

News of the Week.

Report from the Canal Zone.—The report of Dr. W. C. Gorgas, Chief Sanitary Officer, of health conditions in the Canal Zone during the year 1910 has been issued. Summarized it shows that the improvement in general conditions apparent most markedly in 1909 have continued, although the total death rate was slightly increased because of an increase in the number of deaths from violence. A comparison of the deaths and death rates during the last seven years shows the following:

	Number of employes.	Deaths.	Rate.
1904	6,213	82	13.26
1905	16,512	427	25.86
1906	26,547	1,105	41.73
1907	39,238	1,131	28.74
1908	43,891	571	13.01
1909	47,167	502	10.64
1910	50,802	558	10.98

The death rate from disease alone was lower in 1910 than in 1909. Among white employes from the United States the death rate from disease was 2.63 per thousand, and among all Americans, including women and children, 3.64 per thousand, which is a decided improvement over 1909. Deaths from special diseases among all employes are classified as follows:

	Number of Deaths.	
	1909.	1910.
Typhoid Fever	13	13
Dysentery	8	21
Pneumonia	70	73
Malaria	52	50

The death rate of the total population, including the cities of Panama and Colon and the Canal Zone, was 21.18, an increase over the previous year, when the rate was 18.19 per thousand. One death from yellow fever occurred during the year, the patient having arived in Panama from Cartagena only two days before he was taken ill. With this exception no cases of yellow fever, plague, or smallpox occurred on the Isthmus during the entire year.

Middleton Goldsmith Lecture.—Prof. Frank P. Underhill of the Sheffield Laboratory of Physiological Chemistry, Yale University, will deliver the Middleton Goldsmith Lecture of the New York Pathological Society at the New York Academy of Medicine on Saturday evening, March 18, at 8.30. The subject of the lecture will be: "A Consideration of Some Chemical Transformations of Proteins and Their Possible Bearing on Problems in Pathology." All physicians and others interested in the subject are cordially invited to be present.

Harvey Society.—The last lecture of the season will be delivered at the New York Academy of Medicine on Saturday evening, April 1, at 8:30, by Dr. S. Weir Mitchell of Philadelphia, under the title: "A Lecture on William Harvey, the Discoverer of the Circulation of the Blood." The society announces that ladies will be especially welcome at the lecture.

Antivivisection.—A joint hearing before the Senate Judiciary and the Assembly Public Health Committees on the bills introduced into the Legislature for the regulation of vivisection was held in Albany on March 7. Drs. Simon Flexner, James Ewing, William H. Park, and W. B. Cannon spoke against the passage of the bills, which were supported by Dr. Herbert Snow of London and Mr. Frederick Bellamy. The Vivisection Investigation League was recently incorporated in New York City, its avowed purpose being the carrying on of any work for the purpose of arousing public sentiment against vivisection, the investigation of "the practice of vivisection upon animals or human beings," and the holding of public meetings and circulating literature against vivisection. At a meeting held in the Berkeley Lyceum, New York, on March 9, under the auspices of the League for Political Education, Dr. Herbert Snow of London and Dr. Woods Hutchinson of New York debated the subject of vivisection and its value to medicine. The utter diversity of the basic views held by the debaters, as well as of their conclusions, made a logical discussion impossible, and the unmannerly greeting given to some of Dr. Hutchinson's remarks showed clearly the bias of the audience as well as the good breeding of the ladies of both sexes who composed it.

Medical Legislation in Pennsylvania.—*Antivivisection.*—Two bills directed against animal experimentation have been introduced into the Pennsylvania Legislature. One is intended to prohibit experiments on living animals, except for purposes of healing or curing, under penalty of a fine of from $100 to $500, or of imprisonment of from three months to one year. The other bill contemplates prohibiting the administration of curare to animals. Still another bill prohibits the purchase of animals or fowl from minors or persons having no known trade.

In Favor of Electrocution.—A bill has been introduced into the Pennsylvania Legislature making electrocution the legal method of inflicting the death-penalty in the State of Pennsylvania.

To Diminish Idiocy.—A bill has been introduced into the Pennsylvania Legislature providing under suitable conditions for the sterilization of idiots and feeble-minded persons in State institutions under the control of superintendents and courts, and it has been affirmatively recommended by the Committee on Health and Sanitation.

A Fair for Osborn Hall.—An Easter Bazaar in behalf of Osborn Hall, the new club house for Bellevue nurses, 426 East Twenty-sixth street, will be held at the club house on the afternoons and evenings of April 5 and 6, from 2 until 10 P.M. Since the founding of the training school, in 1873, this is the first appeal on the part of Bellevue nurses for public aid of any sort. Long needing just such an attractive homelike place as the club house, so generously dedicated to their use, they now face the problem of providing funds for its maintenance. The Nurses' Registry is to be kept at Osborn Hall, and the restaurant will be open to physicians attending the dispensaries in the neighborhood.

A Modern Hospital in a New York Hotel.—One of the features to be offered by the new McAlpin Hotel, now in course of construction on the southwest corner of Thirty-fourth street and Broadway, will be a fully equipped miniature hospital

where cases, no matter how serious, can be treated with the same care as in the best up-to-date private sanatorium. It is to be arranged so as to be able to accommodate comfortably twelve patients at the one time. Surgeons, physicians, and trained nurses will be in attendance constantly. This hospital will be on the twenty-third floor of the hotel.

New Hospital.—The work of constructing the new Bushwick Hospital at the corner of Howard and Putnam avenues, Brooklyn, will, it is expected, be begun in about two months. The new building, which will be four stories high, will cost about $75,000. It is thought that a large part of this sum will be realized from the sale of the old hospital site.

Columbia University.—At a meeting of the trustees of the University recently it was voted that the head professorship of physiology in the College of Physicians and Surgeons be named the Dalton professorship, in honor of the late Dr. John C. Dalton, who held the chair of physiology from 1860 to 1883, and was president of the college from 1884 to 1889. The professorship is now held by Dr. Frederic S. Lee. The trustees also announced that the sum of $693,000 had been received from the executors of the estate of the late Mr. George Crocker, for the establishment of the Crocker Cancer Research Fund.

Hospital Sold.—St. Andrew's Convalescent Hospital on East Seventeenth street, New York, has sold its present site and will move to 237 East Seventeenth street, overlooking Stuyvesant Park.

Civil Service Examination.—The New York State Civil Service Commission announces an examination to be held on April 1, 1911, for the purpose of filling a vacancy in the position of assistant surgeon in the Soldiers' and Sailors' Home, Bath, New York, at a salary of $1,200 and maintenance. On the same date examinations will be held for vacancies in the corps of trained nurses at salaries of $420 to $600 with maintenance.

The New York Polyclinic Medical School and Hospital gave a dinner at the Waldorf on March 11, at which plans for the new buildings now in course of construction were discussed. Dr. Robert C. Myles spoke of the new enterprise. Among the other speakers were Dr. John A. Wyeth, Dr. J. Riddle Goffe, and Dr. Francis J. Quinlan.

Health Bulletin.—The New York City Department of Health announces that it has undertaken the publication of a monthly bulletin, which is intended for the information of public health officials, physicians, and laymen interested in health problems, and will contain in each issue editorials and special articles dealing with phases of public health work. The bulletin will also contain reports of the activities of the department, the vital statistics of the previous month, and an official account of the acts of the Board of Health, the purpose being to make it an agency for disseminating information regarding hygiene and sanitation and the prevention of disease, particularly with reference to health conditions in New York City and to the department's work as guardian of the health of the people.

Dr. Wilfred T. Grenfell of Labrador arrived in New York from England on March 10, and on the following evening he spoke at a meeting in the Academy of Medicine to a number of hospital internes and medical students.

Hospital Quarantined.—The Memorial Hospital of Brattleboro, Vt., was placed under strict quarantine on March 5, following the discovery of several cases of diphtheria in the institution.

Dies at 110 Years.—Mendel Diamond of New York, who came to this country from Russia many years ago, died on March 6 at the alleged age of 110 years.

To Stop Quackery.—Dispatches from Berlin state that a committee of the Reichstag, which has been preparing a bill to suppress quacks in medicine in Germany, has decided to recommend one forbidding the practice of faith healing or spiritualistic or other mystic treatment of the sick for pay, or where the efficacy depends upon a claim of the possession of miraculous powers, magnetism being exempt. It is said that discussion of the proposed measure brought out stories of most amazing credulity and superstition.

Yellow Fever in Mexico.—The Texas State Department of Health has been advised that yellow fever has made its appearance in Mexico. An effective quarantine against the infected places is urged.

Cholera in Hawaii.—Twenty-five cases of cholera with twenty-one deaths was the record in Hawaii up to March 9. Almost all of the victims are natives.

Bequests to Charities.—By the will of the late Mrs. Letta Searles Cooley of Cleveland, Ohio, approximately $100,000 is provided for the establishment of a hospital in East Cleveland to be known as the Lathrop Cooley Memorial.

Infantile Paralysis in Iowa.—During the year 1910 there were 604 cases of infantile paralysis in Iowa, with 160 deaths. This number was exceeded only in Pennsylvania, which had a total of 1,028 cases.

Death Rate in Chicago.—During the year 1910 the death rate in Chicago was 15.2, which is higher than that of the past two years. The increase is ascribed by the Commissioner of Health to the refusal of the City Council to grant sufficient money for the proper maintenance of the department.

The Women's Medical Society of the State of New York held its fifth annual convention in New York on March 9 and 10, closing with a dinner at the Hotel Astor. Over a hundred women physicians attended the meetings.

Lawrence County (Ark.) Medical Society.—At the meeting of the society held on March 4 at Walnut Ridge the following officers were elected: *President*, Dr. H. R. McCarroll; *Vice-President*, Dr. W. W. Hatcher; *Secretary*, Dr. J. C. Swindle; *Treasurer*, Dr. W. E. Hughes.

Southern Commercial Congress.—The Section on Health of the Southern Commercial Congress, which has been in session at Atlanta, Ga., met on March 10 under the presidency of the Surgeon-General of the Public Health and Marine-Hospital Service. Various public health questions were discussed.

Fourth Councilor District (N. C.) Medical Society.—At the annual meeting held on February 15 the following officers were elected for the ensuing year: *President*, Dr. James J. Philips, Tarboro; *Vice-Presidents*, Dr. Williams Spicer, Goldsboro, and Dr. L. D. Wharton, Smithfield; *Secretary-Treasurer*, Dr. Michael M. Saliba, Wilson.

Charitable Gifts.—The New England Hospital for Women and Children of Roxbury, Mass., receives a bequest of $20,000 under the will of the late Miss Alice M. Curtis of Wellesley.

Tulare County (Cal.) Medical Society.—At a meeting held at Visalia on January 21 the physicians of Tulare County organized a medical society, the following officers being elected: *President,* Dr. T. D. Blodgett, Tulare; *Vice-President,* Dr. Mark Petit, Visalia; *Secretary-Treasurer,* Dr. F. L. Stallings, Lindsay; *Censors,* Drs. Miller, Portersville; Dr. C. M. White, Visalia, and Dr. W. C. Chilson, Tulare. The society will hold monthly meetings hereafter.

Stephenson County (Ill.) Medical Society.—At the annual meeting on January 27 the following officers were elected: *President,* Dr. C. L. Mease; *Vice-President,* Dr. J. H. Stealy; *Treasurer,* Dr. N. C. Phillips; *Secretary,* Dr. J. Sheldon Clark.

Red River Valley Medical Association.—At the annual meeting at Crookston, Minn., on January 25 the following officers were elected for the ensuing year: *President,* Dr. G. A. Morley, Crookston; *Vice-President,* Dr. O. F. Melby, Thief River Falls; *Secretary-Treasurer,* Dr. J. F. Norman, Crookston.

Dodge County (Neb.) Medical Association.—At the annual meeting held at Fremont on January 19 the following officers were elected: *President,* Dr. George Haslam; *Vice-President,* Dr. Rupert Davies; *Secretary,* Dr. H. N. Morrow; *Treasurer,* Dr. R. C. McDonald.

Johnson County (Neb.) Medical Society.—At the annual meeting held at Tecumseh on January 19 the following officers were elected for the ensuing year: *President,* Dr. C. H. Davies, Tecumseh; *Vice-President,* Dr. J. Hanson, Elk Creek; *Secretary-Treasurer,* Dr. A. P. Fitzsimmons, Tecumseh.

Northwestern District (N. D.) Medical Society.—The annual meeting of the society was held at Minot on January 20, when the following officers were elected: *President,* Dr. J. D. McConnell, Minot; *Vice-President,* Dr. J. S. Davies, Granville; *Secretary-Treasurer,* Dr. J. Roy Ringo, Minot.

Texas Association of Medical Directors.—At the annual meeting in Austin on January 25 the following officers were elected: *President,* Dr. J. S. Lankford, San Antonio; *Vice-President,* Dr. N. A. Olive, Waco; *Secretary-Treasurer,* Dr. M. M. Smith, Dallas.

The Medical Society of the Missouri Valley will hold its twenty-third semi-annual meeting at St. Joseph, Mo., on March 16 and 17, 1911. The oration in surgery will be delivered by Dr. Charles H. Mayo and the oration in medicine by Dr. Heinrich Stern of New York. Dr. Charles Wood Fassett of St. Joseph is the secretary of the society.

Northern Medical League of Philadelphia.—Under this title the physicians and druggists of the northern section of Philadelphia have formed an association for the purpose of furthering the mutual interest of its members, financially as well as scientifically and socially, and to bring about a better ethical relationship between the two professions and among the physicians themselves. Bimonthly meetings will be held, one to be a scientific meeting in the nature of a post-graduate course, the other devoted to problems concerning the welfare of the physician and druggist. The following officers have been elected to serve for the first year: *President,* Dr. M. V. Leof; *Vice-President,* Dr. G. Azoff; *Treasurer,* Dr. H. Stembler; *Secretary,* Dr. H. Snyderman.

Hall County (Ga.) Medical Society.—At the annual meeeting held in Gainesville on January 17 the following officers were elected for the ensuing year: *President,* Dr. John B. Rudolph; *Vice-President,* Dr. J. H. McClure; *Secretary-Treasurer,* Dr. A. B. White.

Clinton County (Ia.) Medical Society.—The following officers were elected at the annual meeting of the society held in Clinton on January 18: *President,* Dr. F. M. Keefe; *Vice-President,* Dr. F. O. Kerschner; *Secretary,* Dr. M. E. Brown.

Dubuque County (Ia.) Medical Society.—The annual meeting of the society was held in Dubuque on January 10, the following officers being elected: *President,* Dr. E. R. Lewis; *First Vice-President,* Dr. W. L. Becker; *Second Vice-President,* Dr. A. L. McNeil; *Secretary,* Dr. M. J. Moes.

Hunt County (Tex.) Medical Society.—At the December meeting of the society the following officers were elected: *President,* Dr. E. P. Becton; *Vice-President,* Dr. T. B. Spaulding; *Secretary,* Dr. J. A. Bush. The society issues an interesting announcement of the program arranged for its meetings for the next six months.

The International Medical Association to Aid in the Suppression of War will meet in Paris in September, 1911, the exact date to be fixed later. Medical men desiring to attend the congress are requested to communicate with the president, Dr. J. A. Riviere, 25 rue des Mathurins, Paris.

New York State Homeopathic Society.—At a meeting of the society held in Albany on February 14 the following officers were elected: *President,* Dr. Oranda S. Rich, Brooklyn; *First Vice-President,* Dr. George R. Critchlow, Buffalo; *Second Vice-President,* Dr. Murcena S. Ricker, Rochester; *Third Vice-President,* Dr. George H. Jenkins, Binghamton; *Secretary,* Dr. Bert B. Clark, New York; *Treasurer,* Dr. Reeve B. Howland, Elmira.

DeWitt County (Texas) Medical Association.—At the annual meeting held in Cuero on February 7 the following officers were elected: *President,* Dr. G. W. Allen, Yorktown; *Vice-President,* Dr. W. D. Finney, Cuero; *Secretary,* Dr. B. J. Nowierski, Yorktown; *Censor,* Dr. R. M. Westphal, Yorktown.

The Minnesota Academy of Ophthalmology and Oto-Laryngology was organized at a meeting of Minneapolis and St. Paul physicians, which was held in the former city on February 8. The officers elected are as follows: *President,* Dr. Howard McI. Morton, Minneapolis; *Vice-Presidents,* Dr. J. W. Chamberlain, St. Paul, and Dr. John F. Fulton, St. Paul; *Secretary-Treasurer,* Dr. E. H. Parker, Minneapolis.

Langlade County (Wis.) Medical Society.—At the annual meeting held on January 28, officers for the ensuing year were elected, as follows: *President,* Dr. M. J. Donohue; *Vice-President,* Dr. George H. Williamson; *Secretary-Treasurer,* Dr. J. C. Wright.

Brown County (Wis.) Medical Society.—Officers for the ensuing year were elected at the annual meeting held at Green Bay on January 27, as follows: *President,* Dr. R. C. Buchanan; *Vice-President,* Dr. Felix Moreaux; *Secretary-Treasurer,* Dr. T. J. Oliver.

North Idaho District Medical Society.—At the annual meeting on January 9 at Lewiston the following officers were elected: *President,* Dr. W. H. Carrithers of Moscow; *Secretary-Treasurer,* Dr. Aspray of Moscow.

Obituary Notes.—Dr. John Williams Coe, who died of pneumonia March 6, 1911, after a short illness, was born June 19, 1872, at Meriden, Conn. His parents were John W. and Sarah Williams Coe, both of early New England stock. His father's family were descended from that Robert Coe to whom, in 1639, the deed of sale of Stamford, Conn., was given by the Indians. Dr. Coe was graduated from Yale from the Sheffield Scientific School in 1893. During the following year he continued his study there with Professor Chittenden and later spent several months in special laboratory work at the University of Greifswaldt in Germany. His medical course was taken at Johns Hopkins, from which he graduated in 1898. He was an alumnus of the Presbyterian Hospital, a member of the Lenox Medical and Surgical Society and the Academy of Medicine, and an instructor in the Cornell Medical School. His practice was exclusively in diseases of the skin and genitourinary organs. He was an excellent laboratory technician and had given to the pathology of these diseases much excellent investigation. He was a thorough student, a competent practitioner, and a man of most admirable qualities.

Dr. William Wheeler Hewlett of Babylon, N. Y., a graduate of the Bellevue Hospital Medical College in 1869, a member of the New York State and Suffolk County Medical Societies, and of the Associated Physicians of Long Island, died suddenly at his home on March 5, aged 63 years.

Dr. Daniel Maynard Burgess of New York, a graduate of the Medical Department of New York University in 1855, a member of the New York State and County Medical Societies, and for thirty years health inspector for the United States Government at the Port of Havana, died at his home on February 28, aged 82 years.

Dr. Hosias M. Schiemann of New York, a graduate of the University of Kazan, Russia, in 1889, died on March 10 in Mt. Sinai Hospital from injuries received in an accident some time before.

Dr. J. A. Parsons of Bowersville, Ga., a graduate of the Atlanta Medical College in 1884, died at the Grady Hospital, Atlanta, on February 25, aged 49 years.

Dr. Edwin H. Carter of Des Moines, Iowa, a graduate of the Eclectic Medical College in 1865, and of the Rush Medical College, Chicago, in 1897, died at his home after a short illness on February 25, aged 74 years.

Dr. Elmer H. Dodson of Spencer, W. Va., a graduate of the Bellevue Hospital Medical College in 1882, and for fifteen years connected with the Hospital for the Insane at Spencer, died at his home on February 22, aged 59 years.

Dr. Herschel V. Logan of Americus, Ga., a graduate of the Medical Department of the University of the South, Sewanee, Tenn., in 1897, died at his home on February 26, aged 40 years.

Obituary.

HENRY PICKERING BOWDITCH, M.D., LL.D.

BOSTON.

Dr. Henry Pickering Bowditch, the eminent physiologist and formerly professor at the Harvard Medical School, died March 13 at his home, in Jamaica Plain, aged 71. Dr. Bowditch served in the Civil War, retiring with the rank of Major. He then entered the Harvard Medical School from which he was graduated in 1868. He studied physiology in France and Germany, and on his return in 1871 was appointed assistant professor of physiology at Harvard, becoming full professor in 1876, and receiving the appointment of Higginson professor in 1903. From 1883 to 1893 he was dean of the Medical School. He retired from active work in 1906.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

ANTIQUITY OF THE MODERN MAN, HUNTERIAN LECTURES—BONE CASES—SANITARY SERVICE OF TERRITORIAL FORCE—PAPILLEDEMA OR OPTIC NEURITIS—HEREDITY—POOR LAW CONFERENCE AND FEEBLE MINDED—DETECTION OF BLOOD STAINS—SMALLPOX OUTBREAK—MEASLES—OBITUARY.

London, February 24, 1911.

Professor Arthur Keith, conservator of the Hunterian Museum, opened a course of lectures on the "Fossil Remains of Man" at the Royal College of Surgeons on Monday. He described the remains found by the late Mr. Robert Elliott in 1888 at Galley Hill and which Mr. E. T. Newton holds were embedded when the level of the Thames was 90 to 100 feet higher than it is to-day. The remains are now in Mr. Frank Corner's collection. For some time geologists refused to regard them as equal to the 100 feet in point of time, but Mr. Newton's views seem of late to prevail. The antiquity of the Galley Hill man, Professor Keith said, must be measured by the work done by the Thames which has not only worn its estuarian valley down 90 to 100 feet, owing to the elevation of the land, but has also eroded and filled up a channel 40 to 50 feet below its present level. At the lowest estimate the bed of the river is held to have been lowered and raised 170 feet since the upper terrace of gravel (where the remains were found) was laid down in post-glacial times. The level and aspect of the valley have altered but little since the Roman and there is no reason to suppose that changes were at any time vaster; one may safely allow, said the professor, 1,000 years for every foot. On this basis the antiquity of the Galley Hill man may be 170,000 years. Judging from the parts of the skeleton found, whatever the age, the lecturer pronounced the man of essentially modern type and he is the only representative of thousands of generations of Englishmen spanning the vast period of human life in this country from glacial to neolithic times.

In Wednesday's lecture the Heidelberg jaw was considered as rendering it possible to form a conception (might one say a guess?) of the stage of evolution reached by man between the pliocene and glacial periods. At first sight this lower jaw appeared more anthropoid than human. The muscles of mastication had been developed more than in any other human race. Whatever the food, it must have demanded much pulverization. Then this jaw took part in the mechanism of speech and the modern jaw was held to be adapted to this characteristic of mankind. In the Heidelberg jaw the lecturer saw an intermediate stage, representing the evolution from the simian to the human chin as we now know it. The parts would at the most have reached a primitive stage in the evolution of speech.

Bone cases were prominent at the Clinical Section (R. S. M.) on the 10th inst. One was mollities

ossium of forty-five years duration in a single woman of fifty-eight who did not begin to walk until her third year and then awkwardly until she was thirteen, when she took to her bed. Dr. Simmons showed the skiagraphic appearances. The bones generally were translucent and light in texture; the shafts of the long ones thin, the compact layer narrow, and the central canal wide. The deformities suggested that the bones were slightly plastic and yielded to the stress on them. The long ones bent and the pelvis showed the effects of weight. Hands and feet scarcely altered. Skull retained its shape, having no muscle pulls on it.

Another case was called "imperfect osteogenesis." It was a girl of eight, the second of four children. The bones were said to have been "soft from birth," but a fracture occurred on the fourteenth day. Many fractures since, usually from slight injuries. No signs of rickets or syphilis. The disease seemed to be arrested two years ago and the limbs were placed in the best position, but the improvement did not last. At present there are bosses above the ears, on both sides, spinal lordosis, old fractures, and other deformities.

Another case was a boy of seven. At three he fell and broke his right femur. A large swelling developed at the site and sarcoma was diagnosed but operation refused. Lower half of both legs gradually bent. Two years ago right forearm broken in a fall. Two months ago left upper arm broken and was set. On removing splints a fusiform swelling of bony hardness was found nine and one-half inches in circumference. A skiagram showed this as a mass of trabeculated bone between the fractured ends, under the periosteum, and in the flexor muscles, but a large part of the swelling threw no shadow. The whole length of right femur was occupied also by a fusiform swelling and the skiagram showed the whole shaft expanded and the trabeculæ arranged as wide-meshed cancellous tissue, as if filled with cysts. Similar appearances elsewhere.

Remarks by members were to the effect that mollities was congenital and led to fractures of the more centrally placed bones. Osteogenesis was acquired and led to bending, oftener below the knee. In the third case fibrous osteitis was present also.

Lieutenant Colonel C. H. Melville, professor of hygiene at the Royal Army Medical College, gave an address to the Society of Medical Officers of Health on the 10th dealing with the work of the sanitary service of the Territorial Force in case their districts should ever be occupied by troops. He said 106 Medical Health Officers had offered their services on mobilization and their assistance would be of great value in case of invasion—not only on account of their scientific attainments, but even more on the extent of their local knowledge and experience of civil sanitary administration. The health of our army in the field depended much on that of the civil population where it was quartered and the efficacy of sanitary measures not of a purely emergent nature largely depended on the extent to which they chimed in with local machinery. In one important point, the prevalence of disease in a locality, the Medical Health Officers could give authoritative information. He should remember soldiers were apt to be careless about sanitation, they were accustomed to be spoon-fed in such matters. The Medical Health Officers should cooperate with the military in the cleansing of a battlefield after an action, and in such an overcrowded country as this cremation would be necessary. The connection between the civil and military sanitary machinery must be maintained and every officer who promised to serve on mobilization should see that his services would be worth having.

Histopathology of Papilledema was the title of a paper read at the Ophthalmalogical Society on the 9th inst. In it Drs. Paton and Holmes, basing their statements on the examination of sixty eyes from cases in the hospital for paralysis, said optic neuritis was a simple, congestive edema in no way inflammatory. Any inflammation would only be secondary and limited in distribution. Hemorrhages seen were chiefly congestive. The large white patches on or near the disc were due to degeneration of the nerve fibers and they might undergo fatty change. The changes produced as the disc became otrophic were described and illustrated by lantern slides. Mr. S. J. Taylor asked if any case confirmed what he found—that the earliest evidence of optic neuritis was in the upper and inner part of the disc, to which Mr. Paton replied affirmatively. It nearly always began in the upper border, but involved the lower later. When only the upper border showed edema there was shrinkage of tissue.

Dr. F. W. Mott has just concluded a course of lectures at the Royal Institution on "Heredity," a subject which has for a long time served as a sort of battle ground for differing scientific opinions. Transmission of disease to children was, he said, rather, if it existed, only a predisposition to that disease. There was no proof that the drink habit was transmitted by drunkards to their offspring. On the other hand genius and madness were often allied. Julius Cesar and Napoleon were both, he considered, epileptics.

Dr. Archdall Reid treated the subject at the Author's Club where he was entertained as the "principal guest" last week. It is the custom of this club to invite some author who has made a subject his own to dine and address them on the subject. Dr. Reid said evolution implied adaptation to environment, degeneration the contrary. Man and the beetle could live in their own environments but not in one another's. The right theory of heredity as of evolution must fit in with this fact. Only one did, Darwin's natural selection. Selection implied mortality—the fit survived, the unfit perished. Many died young. Who? The weakest against microbic diseases. One source of elimination was alcohol to which people varied in susceptibility. Were slum children unhealthy because of heredity or of their surroundings? The races most exposed to slum life were the Chinese and the Jews and they had not grown degenerate. There had been a selection and they had undergone protective evolution. So with consumption and other cases—always there was this protective evolution. Children resembled their parents on the whole, a man produced a man, a beetle produced a beetle, but there were variations in details. Offspring were not rendered degenerate by their parents but races underwent evolution through the fires to which they had been exposed. Nor was it the illnesses that changed a race—it was the illnesses which ended in death.

The thirty-ninth annual Poor Law Conference has been sitting this week, 280 boards of guardians being represented. It is perhaps only natural that these gentlemen should feel that in the discussions, one may almost say the disputes, that have been going on respecting poor law reform their services have been overlooked. It should be remembered

that they have always been possessed of local knowledge. They have covered the country with the buildings necessary to carry out the intentions of the legislature, they were early in the field in education of the children and in providing infirmaries for the sick. No one doubts that they have made mistakes nor denies that abuses have crept in, but they may fairly ask whether more so than in other institutions. One of the papers submitted at the conference argued that the guardians as administrators should consolidate rather than break up and there should be no class in need of maintenance at the public expense who ought not to be eligible for treatment under the Poor Law. On the other hand it was said that what guardians might or might not do depended very much on whether they took a narrow or a generous view of their statutory powers. The boarding out system was also discussed as well as heredity. As to this one guardian declared it was being used as a blind to cover the main causes of degeneracy, which were drink, immorality, insufficient food, and environment. England was not going to ruin because of the feeble-minded but because of the strong-minded who were also evil-minded.

On another day this problem was taken up by Sir William Chance, who urged that it was of national concern, as a really feeble-minded child would always remain so. He believed the defect was hereditary, from the facts brought out by the Royal Commission's Report (1908). At present these children were left to the Poor Law, educational authorities, and voluntary efforts. He agreed with the commission that there should be one authority to control every class of mental defectives, whether lunatics, idiots, imbecile, feeble-minded, or epileptics. There could be no good reason for leaving one class of mental defectives—and a dangerous class—under a different authority from that which dealt with the other classes. Was it not hypocritical to talk of the liberty of the subject when it was proposed to give compulsory power over persons who scarcely knew what liberty meant, incapable of taking proper care of themselves and often irresponsible for their actions?

The detection of human blood by the serum test as related in evidence in a recent murder trial has excited public attention. At the Royal Institute of Public Health the process was demonstrated on Monday by Dr. Rajchman, assisted by Mr. E. Garratt. It was shown that on receiving a piece of a stained garment the threads are teased out by the expert and a portion placed on a watch glass with normal salt solution which has the density of serum. Blood will dissolve in about twelve hours and the liquid is then put in a small tube and anti-human serum added. If the stain is of human blood the characteristic precipitate of albumen at once appears. Formerly the ablest expert could only say the blood was mammalian, but by this method he can differentiate that of various animals because the serum of any one gives the reaction to the blood of that animal only. It has been suggested that the process might be utilized for other purposes, but the detection of crime is first in importance.

Yesterday it was announced that an outbreak of smallpox had occurred in East London and eleven cases had been taken to the smallpox hospital. This morning fourteen additional cases are reported. The first case was in a girl of twelve, an out patient at a hospital. She was at first treated for chicken pox, but when worse was taken to the Infirmary, where the doctor, feeling uncertain, obtained the opinion of one of the medical officers of the asylum board, who diagnosed it as the more serious disease and had her transferred to the board's hospital. The delay in recognizing it was unfortunate, as the contacts in the child's family and in the infirmary soon fell ill. The outbreak began in the same street as did the last epidemic. All the authorities are determined that everything shall be done to stamp out the disease.

Measles is very prevalent all over the country and the school medical officers are doing their best to restrict its spread among the children—no easy task considering the rapidity of infection. Six hundred children have been admitted to the asylum board's hospital, where four hundred and seventy-five remain; fifty-five have died.

Surgeon Lieutenant Colonel H. F. H. Hensman, late First Life Guards and A. M. S., died on the 21st inst., aged seventy-one. He qualified in 1861, became assistant surgeon in 1862, served in the Umbeyla campaign in 1863. In the South African war in 1899-1900 he commanded the Maine, was mentioned in dispatches, received the Queen's Medal, and was created C. M. G. Promoted to rank of colonel in 1902 and retired in 1904.

Another lieutenant colonel, T. T. Gardner, a Guy's man, has also died. He passed the two London colleges in 1855 and joined the A. M. S. in 1858, was attached to the Ninetieth Regiment of the artillery, and retired in 1881.

OUR PARIS LETTER.

(From Our Regular Correspondent.)

ABORTIVE TREATMENT OF SYPHILIS—ANTITYPHOID VACCINATION—LITHIASIS OF THE BILIARY DUCTS—PTOSIS OF THE STOMACH.

PARIS, February 15, 1911.

At the Academy of Medicine the subject of the abortive treatment of syphilis was considered. Ehlers of Copenhagen describes a case in which a patient 40 years of age, syphilitic for eleven years, and a general paralytic, was treated with 606 and died five days afterward from paralysis of the heart. Ehlers thinks that the patient died undoubtedly of arsenical poisoning. After treating seven syphilitics who had been refractory to mercury with 606 he followed them after the injection and was able to see that the amelioration, often miraculous, did not last more than seven to fifteen days in severe cases and a month in others. In all seven patients recurrence occurred, for the most part as serious as before the treatment. Ehlers is in favor of not using 606 until we have more knowledge of its action. Hallopeau rejects the use of 606 as dangerous. He believes that we should substitute for it hectine in the abortive and curative treatment of syphilis. The technique is the same as for an injection of morphine, but it should be used in subcutaneous injections in the edge or in the neighborhood of the primary lesion, the customary dose being 20 centigrams dissolved in 1 cm. of sterilized water. The injections should be made daily for about 30 days; this treatment appears to have the same decisive action in all patients. Syphilis attacked in the first thirty days of its evolution is definitely cured. Hallopeau thinks that in hectine we have the only drug useful for the abortive treatment of syphilis. The definite success of its use locally, following definite rules, is constant. If

there are failures they are to be attributed to the use of a different technique. Cure being complete, one may authorize marriage after this curative treatment, from the moment when the Wassermann reaction is negative. As a result of this communication a commission was appointed by the academy to examine the conclusions of Hallopeau, composed of Fournier, Balzar, Gaucher, Hallopeau, Pinard, and Vaillard.

Antityphoid vaccination was the subject of a paper by Vincent, following a communication from Chantmesse. The frequency of typhoid fever justifies the necessity of not neglecting and of using proper means for reducing the spread of this disease. Is antityphoid vaccination among this number, and may we hope by its employment to obtain an effective prevention of this disease? Antityphoid vaccination has been applied with success for some years in the English, German, and American armies. More than 100,000 subjects have been vaccinated. The antityphoid vaccines generally employed have been cultures of the bacillus of Eberth killed by heat. Antityphoid vaccination does not make the disease disappear entirely in the regions in which it has been applied, but it diminishes its frequency. Besides this, the persons who do contract the disease in typhoid neighborhoods are attacked much less severely than unvaccinated subjects. The immunity assured by antityphoid vaccination appears to be prolonged to one to four years. Whatever vaccine be employed, antityphoid vaccination has shown itself to be without danger to the numerous individuals who have been inoculated. Antityphoid vaccination should not be formally forbidden except among subjects who are threatened with typhoid fever, for it may aggravate the infection. Antityphoid vaccination should be done only in perfectly healthy subjects, exempt from all taints, visceral or otherwise. Among the persons who may be expected to be benefited by antityphoid vaccination are physicians, internes, students of medicine, male and female nurses in hospitals, young people coming from a healthy region to the cities which are habitual foci of typhoid fever, the population of cities, soldiers and marines who are employed in colonies where typhoid fever is endemic. To sum up, Vincent thinks that there is reason for recommending the employment of antityphoid vaccination as a rational prophylactic measure to reduce to reasonable proportions the frequency and severity of typhoid fever. This recommendation includes all persons whose professions expose them to direct or indirect contagion by the bacilli of typhoid fever. Delorme thinks, on the contrary, that antityphoid vaccination is at the present time a very uncertain method of immunization, incomplete, sometimes even dangerous. In spite of real progress, it is not as yet so devoid of inconveniences (accidents, local and general, numerous contraindications) that one should recommend it, even tentatively, in civil circles or in the army. Netter's views are entirely opposite to those of Delorme. He thinks that we should not order vaccination, but should recommend it as an opportunity. According to Netter antityphoid vaccination confers an appreciable immunity, it lessens the gravity of this disease and its relatively slight incoveniences are daily diminishing in frequency. Landouzy thinks that antityphoid vaccination is inoffensive and efficient. For him the advantages of vaccination overtop the inconveniences and difficulties. To refuse to indicate the opportunity presented by vaccination would be not only to serve badly the national defense and the prosperity of the country, but also to lower the development of the medical sciences of the present day. Chauffard thinks that there can be no doubt that antityphoid vaccination has given proofs of its value, and that, even if it may give rise to painful reactions, it is still without danger if the indicated precautions are taken. But for the present it cannot enter into general use and must remain a treatment of exceptional cases, applicable only to an organization of special technique, or under careful control, which remains, in France, to be prepared. We should only attempt it in special conditions, in which the risks of contamination are considerable. The protection against professional typhoid fevers can and should be demanded in a methodically organized and observed typhovaccination. To act otherwise would be to be lacking in a medical and social duty. Lithiasis of the biliary passages was considered by the Surgical Society. Hartmann presented a memoir of Gosset on lithiasis of the biliary passages, with a series of twenty-five cholecystectomies. In his paper at the Surgical Congress in 1908, Gosset showed that of seventy-eight cases of death there were sixteen by hemorrhage and he added that we should take special care in hemostasis and particulary in ligature of the cystic artery, which should be ligated in full view and with an isolated ligature. Gosset and Desmarets have described the varieties of the cystic artery, which permits of the description of an operative method of ligature which is always available, whatever be the anatomical variations which we find present. The cholecystectomies which have been done by Gosset were executed in two different conditions: 1, as a primary operation in lithiasis of the gall bladder alone; 2, as a complementary operation after opening and drainage of the hepatic duct.

Ptosis of the stomach was the subject considered at the Medical Society of the Hospitals. An interesting communication was made by Gaston Durand and Raulot-Lapointe. Enriquez has done most to popularize the systematic employment of radioscopy as a means of investigation of the stomach and intestine.

Radioscopy has done more—facilitating the diagnosis of ptosis of the stomach, it has, at the same time, given an exact measure of the value of the means employed to combat it. Enriquez had the idea of controlling by the *x*-rays the means employed to retain gastric ptosis, and he was able to see that the belts most perfectly applied, according to the rules prescribed by the authors who had advocated them, raised the lower border of the organ by 1 cm. at least when the stomach was not empty; but that, on the other hand, in all cases of empty stomach these same belts sagged down regularly by 1 or 2 cm. and even more, depressing the lower border of the stomach. To obviate this grave defect, Enriquez proposes to reinforce the belts by means of a pneumatic cushion of variable size and of a special shape which he called "hypogastric cushion." By the application of such an apparatus all gastric ptoses can and should be cured with the express condition of using a means of retention which can adapt itself to every particular case. The cushion of Enriquez has the shape of a shuttle and presents this peculiarity that the superior border has a sort of bellows attached, which, when it is filled, forms a third face, supe-

rior and horizontal. This cushion compresses like a wedge against the abdominal wall, raises and supports the mass of intestines and stomach, as can be seen by the *x*-ray examination. It is unnecessary to insist on the value of the radioscopic examination in all cases of ptosis, as well for diagnosis as for a control of the immediate and remote effect of the belt. Without this examination the belt may be more injurious than useful.

INSANITY AMONG BRAIN-WORKERS—SPECIFIC REACTION FOR ECHINOCOCCUS FLUID—DEVELOPMENTAL DISTURBANCES OF THE TESTES IN CHILDHOOD—RUDOLF CHROBAK.

VIENNA, February 2, 1911.

DR. KOLOMAN V. PANDYS, head physician of the public insane asylum at Lipotmezo, has investigated the causes and the progress of mental diseases among physicians and other intellectual workers. He examined the medical histories of 12,000 insane men. Paresis was the dominant affection. Of the insane physicians over forty years of age, 77 per cent. suffered from paresis, while this was found in insane lawyers to the extent of 89 per cent. In the course of the last forty years eleven actors had been admitted, all suffering from paresis. Of officers over thiry-six years old, 94 per cent. suffered from paresis, while those under thirty-six years furnished 75 per cent. Under the age of thirty-six years, of the physicians 29 per cent., of the judges 60 per cent., and of the musicians 26 per cent. suffered from paresis. It was found that at this age, in comparing the brain-workers with the common people, the former had 31 per cent. and the latter only 12 per cent. suffering from paresis. Above the age of thirty-six the relationship was different; the brain-workers showing 72 per cent. and the rest of the population 75 per cent. With respect to the excess of paresis the investigations of Pandys as to its etiology are of particular interest. In doubtful cases the Wassermann reaction proved that these were undoubtedly of syphilitic origin. The remarkable frequency of paresis among brain-workers is attributed to their greater opportunities for venereal excesses and the acquisition of lues. Paresis was found most frequently in cases in which the original syphilitic infection was treated but slightly or not at all. In the nonparalytic cases alcoholism was the causative factor in the following percentages: physicians, 9; lawyers, 15; judges, 41; architects, 30; and musicians, 33. The elimination of lues and of alcoholism would have saved 53 per cent. of Hungarian intellectual workers from insanity

Dr. Bernhard Vas of Budapest has made interesting investigations upon the recognition of echinococcus fluid with the aid of a biological reaction. The serum of the suspected individual was capable of giving a positive test when the echinococcus fluid was used as an antigen for fixing the complement. This test was found to be specific.

Dr. Joseph Kyrle has investigated the developmental disturbances of the testicles in childhood. He found that the majority of individuals dying during childhood have undeveloped testes. This was apparently the manifestation of some law, possibly a phase of natural selection, by means of which the least fit would be most readily eliminated.

The Vienna faculty has recently suffered a new loss in the death of Rudolf Chrobak. Hardly had the grave of the illustrious director of the new gynecological clinic in Vienna, von Rosthorn, been covered, when the sad news flew through the medical world, "Chrobak, the master of all, has died" The latter was born in the year 1843, entered the University of Vienna, and received his medical degree at the age of twenty-three. After his entrance into the then famous clinc of Oppolzer, he soon dedicated his activities to gynecology, in which he rapidly attained the leadership. It is of particular note that in the essentials Chrobak was self-taught, his conceptions of disease, his entire medical thinking were, throughout, original. As early as the year 1871 he qualified as Privat Docent in gynecology, therefore becoming one of the first representatives of a specialty that was just then branching off from general medicine. His gynecological lectures soon became known throughout the world. In the midst of these activities it is surprising that he found time to carry on research work in Brücke's famous physiological laboratory. He did not give up this interest in physiology even when he was called to fill the vacancy left by Breisky in the second gynecological clinic. Even before this he had received the title of professor extraordinary. The entire faculty felt the impress of his remarkable personality. Chrobak was an accomplished speaker. It is noteworthy that leading spirits in the domain of medicine have so often been masters of style. One may cite Du Bois-Reymond, Bergmann, and others. Under the direction of Chrobak his clinic acquired a dominating influence; he founded an entire school equally important from the viewpoints of science, medical art, and ethics.

OUR BERLIN LETTER.

(From our Regular Correspondent.)

ANAPHYLAXIS—ITS MECHANISM—RELATION TO IMMUNITY — ANAPHYLACTIC DISEASES — ANAPHYLAXIS AND INFECTIOUS DISEASES.

BERLIN, January 15, 1911.

HYPERSUSCEPTIBILITY, or anaphylaxis, is beginning to play a large rôle in medicine. Almost every day the results of new investigations in this field are being published, results which apparently indicate that our pathological conceptions may undergo a radical reform, provided that the newly discovered facts stand the test of criticism. In this connection we may note the communication presented by Friedberger before the Society for Internal Medicine, January 9, 1911. His paper is entitled "The Nature and Significance of Anaphylaxis." By the latter is meant the increased sensitiveness of the animal organism to the administration of foreign proteid. The fundamental experiment is as follows: If into a guinea pig a tenth of a milligram of the serum proteid of a sheep is injected subcutaneously, and if at a later period, as early as after ten days, five milligrams of the same proteid are injected into a vein, the animal goes into convulsions, has asphyxia, and dies. Anaphylaxis may be transmitted passively, for if a guinea pig be injected with blood serum from another guinea pig already rendered anaphylactic, the former will acquire this property. Similarly the offspring of an anaphylactic animal will be anaphylactic if the mother has acquired this property during gestation.

It must be accepted that in this case of possible transmission, as in the passive transmission of

immunity, the injected proteid (antigen) evokes an antiproteid (antibody). Friedberger conceives anaphylaxis as a proteid—antiproteid reaction occurring *in vivo*, in which the antibody always reacts specifically towards the antigen, which may be of bacterial or of animal proteid nature. With the first injection of antigen there is no antibody present. Parallel with the formation of the antibody, this unites slowly with the antigen, with the splitting off of poisonous decomposition products from the latter. The gradual splitting off is without harm to the body. Upon the reinjection of the antigen there occurs a sudden union of the latter with the antibodies already present, so that there is suddenly produced a large quantity of poisonous decomposition products, with the result that the organism succumbs to the action of the latter. If upon the reinjection of antigen, only a small quantity is injected, not enough poison is produced to kill the animal. In this case the antigen combines with the antibody, so that for a certain time not enough free antibody is present to furnish sufficient poison upon the subsequent administration of antibody. In this case, upon the reinjection of a harmless dose of antigen, later large doses of the latter may be injected without harm to the animal. This condition of diminished power of the organism to react on account of the failure of the antibodies, is called antianaphylaxis.

Further investigations showed that during anaphylaxis the serum becomes poor in complement. Moreover, if the complement, which is always present in the blood in considerable amount, be destroyed, anaphylaxis does not occur. Hence this phenomenon depends upon three factors: antigen, antibody, and complement, which unite with the splitting off of a poisonous substance. It has been possible to produce this poison, the anaphylatoxin, in the test tube. Thus, if an animal is inoculated with horse serum, and if the serum of this animal, which contains antigen and antibody, be mixed in the test tube with horse proteid, there results from the union of antigen and antibody a precipitate, which, if added to normal guinea-pig serum containing complement, results in the formation of anaphylatoxin.

These investigations have served to throw light upon many obscure problems in practice. The idiosyncrasy of certain persons towards albuminous foods is easily explained on the basis of anaphylaxis. It must be granted that in these persons the antibody corresponding to the offending proteid is normally present. Likewise those persons who immediately after an injection of horse serum get sick or die thereby give evidence of hypersusceptibility to horse serum. These cases are extremely rare. More numerous are those cases in which a second injection, as of antidiphtheritic serum, is given. The second intravenous injection is very dangerous. It has been established that hay fever is an anaphylactic disease. Eclampsia is being studied as regards a possible anaphylactic nature; likewise the idiosyncrasy towards certain drugs.

There is a close connection between anaphylaxis and certain infectious processes. Since the bacteria are nothing but vegetable proteid, the same anaphylactic phenomena are evoked by bacteria as by animal proteids. Anaphylaxis and immunity are the same processes with different end effects. Whether one immunize an animal with bacteria or render it anaphylactic by means of proteid, in both instances a reinjection results in the formation of anaphylactoxin. In both instances a sufficiently large dose causes death. In the case of an immunized individual the bacterial dose is so extraordinarily small that the resulting anaphylatoxin cannot have any fatal effect.

In giving a practical example of this phenomenon Friedberger describes the conditions occurring in pneumonia as follows: In the early days of pneumonia the multiplication of the bacteria leads to an accumulation of bacterial proteid. A portion of the bacteria are destroyed by the antibodies that are being formed. Upon the seventh or the ninth day, after the quantity of antibodies has become very large, the antibodies unite with the bacterial proteid, with the aid of the complement present. There results a copious supply of anaphylatoxin, by means of which the bacteria are destroyed. The cure following the crisis results, if sufficient antibodies are present, to destroy all bacteria, or if the number of bacteria is not so large as to produce a fatal dose of anaphylatoxin. If the supply of antibodies is too small, too few pnuemococci will be destroyed, and the pneumonia will take a protracted course. While the same phenomena may be present in the exanthemata, in other diseases, such as tuberculosis, while anaphylaxis may play an important rôle, it may not be so easily explained. The toxicoses, such as diphtheria and tetanus, are, at any rate, exceptions.

OUR LETTER FROM THE PHILIPPINES.

(From our Regular Correspondent.)

EHRLICH-HATA PREPARATION IN LEPROSY—POPULAR LECTURES ON HYGIENE—TREATMENT OF THE INSANE—HOSPITAL DRAWINGS—RESTRICTING THE USE OF POLISHED RICE—A COUNCIL OF HYGIENE.

MANILA, January 28, 1911.

In view of the favorable press notices which have been published with regard to the two cases of leprosy alleged to have been treated with dioxydiamidoarsenobenzol, or 606, in Russia with good results, it was deemed advisable to request volunteers among the lepers at the San Lazaro Hospital for testing similar treatment here. Many immediately came forward and 0.6 gram of this preparation was injected intravenously in two pronounced cases of leprosy. During the first twenty-four hours there was a moderate febrile reaction, the highest temperature recorded being 39° centigrade. There was a feeling of malaise and one of the patients complained of pain in the joints, but this entirely disappeared within thirty-six hours. Three weeks have now elapsed since the injection was made and there have been no changes in the lesions so far as can be observed, and no untoward effects.

The Bureau of Health has now in course of preparation a set of lectures dealing in a popular manner with hygienic subjects which are to be translated into the various dialects. These are to be delivered by Filipinos throughout the provinces, and are to be illustrated with lantern slides. No effort will be spared to make these lectures popular. Special attention will be given to tuberculosis. Arrangements have been made with local cinematograph companies to secure the films which are now being so successfully used in the United States. It is hoped to enlist the aid of the public schools and of the church authorities wherever practicable.

Up to the present time the Philippine Islands have not been provided with any law by which the disposition of the insane may be regulated. It has

been customary to commit emergency cases under the general police powers of the Government and if any question arose with regard to the legality of the confinement the cases were simply released. It appears that in Spanish times it was not customary to make provisions for the insane. Up to a few years ago it was not an uncommon sight to see insane persons throughout the provinces tied up under houses with dog chains. Since then, however, several insane hospitals have been built and at least all of the more urgent cases are now provided for. The time has, however, arrived when it seems most necessary that adequate legal facilities should exist for the commitment of the insane and properly safeguarding their property rights. To provide for this the Bureau of Health has prepared a draft based upon the law of Massachusetts for consideration by the Legislature.

The fifty free beds which have heretofore been maintained by the College of Medicine and Surgery of the University of the Philippines, at St. Paul's Hospital, were transferred during the first week of January to the Philippine General Hospital, and in addition to these the College of Medicine and Surgery of the University of the Philippines has arranged to support another fifty beds, so that the total number of free beds under its control now amounts to 100.

Steps are also under way to transfer to the Philippine General Hospital the 100 free beds which are maintained by the City of Manila in the St. Paul's and San Juan de Dios Hospitals. It is unfortunate that the withdrawal of the Government support from these two private hospitals will seriously interfere with their finances and possibly curtail their usefulness.

A bill has been drafted and presented to the local legislature which has for its object the discouragement of the use of polished rice in the Philippine Islands. In order to accomplish this purpose it is proposed to impose a tax of 2½ centavos upon each kilogram of rice from which the outer and subcortical layers have been removed and which upon analysis is found to contain less than .4 of 1 per cent. of phosphorus pentoxide (P_2O_5). It is hoped that by doing this rice mill owners can be induced to so change their process of manufacture as to only clean and slightly polish rice and thereby leave the greater portion of the outer layers undisturbed. The persons who have this bill in charge desire it to be distinctly understood that they do not desire to be placed on record as stating that beriberi is necessarily due to the absence of phosphorus, but that the phosphorus test is only applied as a means of arriving at the extent to which the outer layers of the rice have been removed.

The Assembly or Lower House of the Philippine Legislature has passed a bill creating a Council of Hygiene. Briefly the bill provides for a body to be composed of seven members, all of whom must be Filipinos, and are to be appointed by the Governor General. It must hold weekly meetings, have a paid secretary, each member to receive 15 pesos ($7.50) for each meeting attended, and a similar amount for each day upon which they render any service for the government. It shall have the power to abolish any positions in the Bureau of Health now authorized by law and appoint persons to any position in the Bureau of Health without Civil Service examination and at such salary as it may determine. Any regulation made by it shall have the same force and effect as any law enacted by the Legislature. The Director of Health shall be under its complete control and carry out all of its wishes and desires.

It may perhaps be remembered that in 1905 the Legislature abolished the Board of Health and substituted for it a Bureau of Health with a director at its head who is solely responsible. This plan has given excellent results in practice. The record of the past five years shows that great economy was effected, and owing to the quick action which was possible much more work was accomplished than formerly. On account of the fact that responsibility can be quickly fixed where there is a single head, instead of an intangible board, with delays due to lack of quorums, personal differences, there has been a much more businesslike administration. It is generally admitted that the one-head plan has been satisfactory and that the Council of Hygiene is simply a device for making political appointments and places for Filipinos who are unable to pass the Civil Service examinations to take positions of Americans who have won them by merit. The bill now goes to the Upper House or Commission for consideration.

Looking Backward.—W. E. Fay points out the progressive steps in the care and treatment of infants and young children in the Floating Hospital in the past ten years.

Bacillary Dysentery.—A. I. Kendall notes that the following organisms are present in the intestine in bacillary dysentery: the dysentery bacillus (Flexner and Shiga types, or both), *Bacillus coli*, and the streptococcus. These act upon protein in the absence of fermentable carbohydrate and form putrefactive products, some of which may be very toxic. To prevent this the author advises that lactose should be fed in rather small amounts, often repeated, to keep up a stream of this sugar in the alimentary canal, otherwise the proteolytes will be able to attack whatever nitrogenous substances may be present in the alimentary canal between the doses of lactose. Dextrose may be infused, preferably as a 2.5 per cent. solution in physiological salt solution to bring to normal the dextrose content of the blood and to furnish fluid to the patient. This feeding of lactose is intended to accomplish a twofold purpose: to furnish to the host a readily assimilable food, requiring a minimal expenditure of energy to metabolize it, and to change the character of the metabolism of the dysenteric flora from the proteolytic to the fermentative type. This change in the type of the intestinal flora is particularly desirable to prevent further intoxication of the host and to give him a better chance to combat the poisons already absorbed.

Infectious Diarrhea.—H. Bowditch points out the beneficial effect of lactose feeding in the treatment of this condition.

Silver Nitrate Irrigations in Infectious Diarrhea.—R. M. Smith notes that in a certain number of cases of infectious diarrhea in infants an early colon injection of 3 per cent. silver nitrate solution apparently hastens the disappearance of blood and pus from the stools, and shortens the course of the disease. In some late cases, where blood and pus persist in the movements, the ulcers can be stimulated by silver nitrate injections and the stools cleared. Since no harm has been done by the use of silver nitrate injections, and some good results have been obtained, it would seem worth while to give this means of treatment further trial.

Statistics of Infectious Diarrhea.—J. H. Young, on the basis of an analysis of 178 cases of infectious diarrhea in infants, states that the mortality of infectious diarrhea as given in series of cases previously reported varies from 6 per cent. to 50.9 per cent., the latter in cases in which the dysentery bacillus was found. Such variations only show the difficulty in making a diagnosis of this disease from clinical signs. The severe types are easy to diagnose. It is the mild cases that are overlooked, the class of cases impossible to diagnose on clinical signs alone, but only by bacteriological examinations of the stools. It is these mild cases which, as dysentery bacillus carriers, form the most common source for the spread of the disease.

Associated Flora of Bacillary Dysentery.—A. I. Kendall and A. W. Walker state that a longer or shorter time after lactose feedings are started, the fecal flora undergo a rather striking change. The streptococci tend to disappear, the colon and dysentery bacilli diminish in numbers, and longer, slender Gram positive rods take their place. The bacteria in the dejecta increase considerably in numbers as well.

Human Milk for Hospital Use.—F. B. Talbot describes two methods of obtaining human milk for hospital use. In the first of these wet nurses are kept at the hospital, are fed liberally, and supply milk in two ways: the milk is drawn with breast pumps for the very weak babies; the stronger babies are put to the breast. In the second method, milk is collected from nursing mothers in the tenements who are found to have a superabundance of milk. In the hospital the wet nurses supply on an average one quart of milk daily. These wet nurses are paid for the milk which they supply at the rate of 2 cents per ounce.

Diarrhea Due to Gas Bacillus.—A. I. Kendall and R. M. Smith state that apparently there exists a group of diarrhea in infants impossible to differentiate clinically from infectious diarrhea caused by the dysentery bacillus. These cases are associated with the presence of large numbers of gas bacilli in the stools.

Absence of Floor of Tympanum.—D. W. Drury states that when the lateral sinus is large and unusually far forward the bulb is likewise large and the fossa, which is consequently deeper, may arch up into the floor of the tympanic cavity, from which it may be separated merely by a thin and translucent plate of bone which occasionally shows an osseous deficiency.

Intussusception.—B. Vincent reports a case of this condition.

Collecting Urine from Female Infants.—C. H. Lawrence describes an apparatus that he has devised for the purpose. It consists of the thumb of a discarded rubber glove fastened by its distal end to an elliptical opening in a Y-shaped piece of adhesive plaster, and by its proximal end to the open end of a test tube. The adhesive plaster is fastened to the infant in such a manner that the elliptical opening is right over the vulva.

New York Medical Journal.

Report on the Treatment of Syphilis by Intravenous Injections of Salvarsan. A. G. Rytina.
Oily Suspensions of Salvarsan. S. Pollitzer.
Diet in Heart Disease and Arteriosclerosis. L. F. Bishop.
Are We in Danger of Trachoma? A. Brav.
Forecasts of Medical Practice in the Future. T. D. Crothers.
The Operative Technique in Acute Suppurative Appendicitis. W. Bartlett.
Acute Amygdalitis. N. Settel.
Prolonged Epistaxis Associated with Increased Vascular Tension. H. Hays.
Phrenology and Its Founder. J. Knott.

Intravenous Injections of Salvarsan.—A. G. Rytina comments on the efficiency of this drug and states that the intravenous injection is practically harmless, giving rise to neither pain nor complications, and producing better results than are obtained either by subcutaneous or intramuscular injections.

Oily Suspensions of Salvarsan.—S. Pollitzer prepares a suspension by triturating the powder obtained from ten ampoules in 15 cc. of iodipin (10 per cent.). This makes a 40 per cent. suspension of the drug. One cubic centimer, containing 0.4 gram of salvarsan, is injected into the erector spinae muscle.

Diet in Heart Disease.—L. F. Bishop notes the importance of a carefully selected diet in a class of cases in which the heart trouble is part of a general cardiovascular disease, and is of chemical or at least of toxic origin. In these cases the ingestion of protein must be reduced to the safest minimum, namely, 50 grams per day.

Trachoma.—A. Brav notes that trachoma is not so contagious as it has been thought to be. Usually only mild cases present themselves. There is no trachoma problem in this country. Trachoma does not thrive in civilized surroundings. It is a curable disease. Only neglected cases terminate in a reduction of vision. In this country it never leads to total blindness, except, perhaps, among the Indians. Laws on this subject need not be oppressive. Trachoma is not on the increase, but rather on the decrease. A trachoma institute, for the purpose of investigating the various aspects of this disease, exists in Philadelphia.

Medical Practice in the Future.—T. D. Crothers believes that the physician of the future will be employed just as a lawyer is retained by a large business firm. He will make regular visits to the home of his patrons and become acquainted with their home life and habits and advise and correct in questions of danger and peril.

Acute Suppurative Appendicitis.—W. Bartlett describes his operative technic in this condition.

Acute Tonsillitis.—N. Settel notes that in cases in which there are no visible secretions these increase the bulk and tension of the tonsils, and the local and constitutional symptoms are correspondingly more severe. The best local treatment consists in the swabbing over the inflamed surface of a 20 or 30 per cent. solution of silver nitrate.

Prolonged Epistaxis.—H. Hays points out that the epistaxis associated with increased vascular tension cannot be controlled until the tension is lowered. For this purpose he recommends rest and the administration of morphine to the physiological limit.

Phrenology.—J. Knott continues his article on this subject.

Report of a Case of Epidemic Anterior Poliomyelitis. L. F. Frissell.
Simple Method for the Detection of Minute Quantities of Albumin in the Urine. R. Katzenstein.
Abortive Cases of Poliomyelitis. An Experimental Demonstration of Specific Immune Bodies in the Blood Serum. J. F. Anderson and W. H. Frost.

Pyelitis in Infancy.—J. Brennemann describes the clinical picture of this condition as follows: A female infant becomes suddenly seriously ill with high temperature, and recurring chills, especially emphasized by Thompson as characteristic, are valuable symptoms. Another striking symptom is the extreme pallor which comes on after the flushed condition of the first few days. The other symptoms are those of the fevers in general, though the breathing is sometimes accelerated and a slight cough may be present. There is frequently some indigestion, which may lead to a wrong diagnosis. The disorder generally, however, does not differ so much from other acute infections as to be readily diagnosed from them, but a positive diagnosis is made when pus is found in the urine. Commonly the urine is turbid, sometimes even thick and milky, and pus cells singly or in clumps crowd the field. Goeppert has suggested as a minimum diagnostic standard of from six to eight leucocytes in each field of an uncentrifuged specimen. In some cases, however, there is a bacteriuria, the urine swarming with bacilli of the colon type. In some cases constitutional symptoms are lacking; in others these are present, though there is little formation of pus; but such cases are rare.

Esophagoscopy for Sharp Foreign Bodies.—W. Lerche concludes that esophagoscopy is not a difficult procedure and gives the best results in the treatment of these cases with the least discomfort to the patient. The use of instruments in the esophagus, except through the esophagoscope, in case of sharp foreign body, should be abandoned. In every case in which the swallowed foreign body is not recovered an esophagoscopic examination of the esophagus should be made. Even if the foreign body is successfully pushed into the stomach the patient is not entirely beyond danger.

Graves' Disease.—By G. W. Grile. See MEDICAL RECORD, Vol. 77, page 1107.

Sodium Cacodylate in Syphilis.—A. J. Caffrey states that he has had equally as good results with sodium cacodylate as with 606.

Operative Posture.—J. E. Goldthwait describes an apparatus for obviating the strain on the patient in the lithotomy position and thus preventing the postoperative weak back.

Intracranial Surgical Lesions in Children.—C. C. Rogers refers to his surgical treatment of children having impaired mental development associated with malnutrition, in whom medical treatment had been a failure. He found in these cases capillary arterial sclerosis as early as the sixteenth month, the findings and symptoms indicating intracranial pressure, and many of the patients improve after a decompression operation followed by antiluetic treatment. In any case of suspected brain tumor, if it can be located, operation should be performed for the purpose of removing the tumor if possible and at any rate of relieving intracranial pressure with the hope that the tumor can be later removed. The decompression operation must be done before advanced ocular or mental symptoms have appeared. Children presenting paralysis of a hand or leg soon after birth should be closely watched and if the paralysis progresses or if there are signs of intracranial pressure or rapid extension producing progressive paralysis much can be done in the way of benefiting these babies and saving life by making a large opening in the skull and relieving the pressure.

Salvarsan.—H. Fox and W. B. Trimble state that the remarkable tonic effect of the drug was observed in nearly every case and in all there was a slight systemic reaction, but while the general febrile symptoms were slight the local effects were more or less severe. The results of the injections were, from a clinical standpoint, in some respects encouraging, in others somewhat disappointing. In a case of leprosy no change in the lesions or general condition was observed. The effect of the new remedy to cause lesions to disappear rapidly has been startling in some cases, but the authors do not consider them specially brilliant as compared with those of other methods of treatment. In several cases in which mercury had failed, however, salvarsan seemed to succeed. It seems to the authors that the lesions of the mucous membrane yielded more quickly than those of the skin. Relapses were frequent enough to be a little discouraging, but the general results of the treatment were favorable enough to induce a continuance of the experimental treatment.

Internal Secretions.—R. H. Chittenden states that the ductless glands exercise a regulating action on each other; that a disturbance of one is followed by a modification of the action of another. Thus the pancreas and the thyroid seem mutually to inhibit each other. The chemical reactions which are here involved are not yet fully understood. The ductless glands illustrate certain forms of internal secretion of the greatest importance, but the cells of every organ and tissue are continually forming intermediate and end products which, absorbed by the blood and lymph, may serve as stimulants to other tissue cells and influence the metabolic processes. The recognition of this chemical correlation is shown in the functions of the intestines and the sexual organs.

Pancreatic Internal Secretion.—W. G. MacCallum states that extirpation of the pancreas produces profound disturbances, more intense than can be produced in any other way, and one is as yet practically unable to annul these effects with any extract from the gland. It is evident, however, that it does not act quite independently of the other organs of internal secretion and, so far as glycosuria is concerned, the weight of evidence is in favor of the idea that the adrenal secretion is the instrument of the nervous effects on the sugar depots of the body; that it can by itself in some way stir up the tissue to set free sugar into the circulation or mobilize the carbohydrates, and the exact nature of the process, apparently a chemical one, is not clear. The action of the thyroids also in the production of glycosuria is to be considered, and glycosuria also sometimes occurs in disease of the hypophysis, and it has been produced by injection of hypophyseal extract. The author believes that the chromaffin system is concerned, not with the activities of the pancreas, but with the mobilization of sugar; that the pancreas is similarly concerned, not with inhibiting the activity of the adrenals, but with causing the glycolysis of the free sugar, while the secretion of the thyroid, if in excess, interferes with this glycolytic action of the pancreatic ferment.

Thyroid Function.—S. P. Beebe concludes that the thyroid gland furnishes a hormone which may be present in the blood within wide limits in the condition of health, and which stimulates a variety of tissues to a physiological, and at times a pathological, degree of activity.

Early Diagnosis of Poliomyelitis.—L. S. Frissell reports a case of epidemic poliomyelitis diagnosed in the preparalytic stage by lumbar puncture. This disease may simulate any of the infections, especially typhoid fever, influenza, or intestinal toxemia. In this case the slight rigidity of the neck and the increased reflexes were suggested, but only the presence of an epidemic put the author fully on his guard. The exaggeration of the reflexes also, gradually diminishing and disappearing at the time of paralysis only to become exaggerated later, is a point

in evidence as to the general nature of the disease which cannot be exclusively confined to the anterior horn cells. The spinal fluid was examined by Flexner, who noted the fact of its agreement with the character of the spinal fluid of his experimental monkeys. As regards the increase in leucocytes and in the protein reaction it is the only case in which he has followed these reactions in man.

Simple Albumin Test.—M. B. Katzenstein recommends, in the heat and in the contact tests for albumin, the passage of light rays through the urine and observing it at right angles to the rays, the principle being the same as seeing particles of dust in a ray of sunshine. Very minute quantities of albumin can be detected. In specimens in which the author and others had failed to detect cloudiness in all other lights it was easily seen by this method. The urine should always be filtered, especially with the contact test. Any bullseye lantern will suffice for the method.

Abortive Poliomyelitis.—J. F. Anderson and W. H. Frost report the results of experiments on the effect of the blood serum of patients who have recovered from abortive poliomyelitis, and in whom paralysis did not occur, in neutralizing the virus of the disease. While there was considerable variety in the abortive cases, there was in most a fairly distinct syndrome, viz., headache, more commonly occipital, pain and tenderness along the spine; neuritic pain and hyperesthesia of the limbs; restlessness and irritability; prostration out of proportion to the severity of other symptoms; some gastrointestinal derangement, and occasionally other symptoms of nervous derangement—vertigo, delirium, etc. The results indicate that normal human serum may have a germicidal action on the virus of poliomyelitis. If this is so, however, the action has quantitative limits which clearly differentiate it from the action exercised by the serum of persons who have had poliomyelitis. No appreciable difference has been demonstrated between the normal serum of adults and of children in regard to the action on the virus. The serum of persons who have recently recovered from frank attacks of poliomyelitis exhibits a germicidal action on the virus considerably greater than that exhibited by normal serum.

The Immunity Reaction in Diagnosis, Especially of Tuberculosis and Syphilis. W. d'Este Emery.
Operations for Stone in the Male Bladder. W. F. Haslam.
The Treatment of Pneumonia. D. B. Lees.
The Education of the Deaf; Its Present State in England, with Suggestions as to Its Future Modifications and Development. M. Yearsley.
Note Upon the Examination, with Negative Results, of the Central Nervous System in a Case of Cured Human Trypanosomiasis. F. W. Mott.
Remarks on the Treatment of Syphilis with Dioxydiamidoarsenobenzol (606). C. F. Marshall.
Contributions to the Physiology and Pathology of the Assimilation of Albumin. S. A. Arany.
A Case of So-called Insusceptibility to Vaccination. J. D. Staple.

Immunity Reaction in Tuberculosis.—W. d'Este Emery notes that the results in the application of the Bordet Gengou reaction in tuberculosis have been various, some authors finding the reaction of some value, others finding it quite useless.

Operations for Vesical Calculi.—W. F. Haslam continues his historical survey of this subject.

Treatment of Pneumonia.—D. B. Lees emphasizes the importance of the early discovery of the local focus. The initial lesion of pneumonia is to be attacked by the application of two icebags, so placed as to include between them the inflamed area of lung. The reason for this procedure is that the pneumococcus is very sensitive to changes of temperature. Growth cannot take place below 28° C. The greater the virulence of the pneumococcus the more marked is its susceptibility to surrounding influences. In carrying out the local treatment by means of icebags it is necessary to watch the right auricle. If this becomes dilated one should relieve the right heart by the application of leaches before the icebags are applied. The feet of the patient must be kept warm. In addition to the local treatment, the author advises the continuous inhalation of volatile antiseptics. Vaccine treatment is also recommended. The precise state of the right heart is the most urgent question in pneumonia. The most powerful cardiac stimulant in pneumonia is bleeding. Next in value come strychnine and oxygen. The inhalation of alcohol has a remarkably beneficial effect in cardiac failure.

Education of the Deaf.—M. Yearsley urges the need of a classification of the deaf child which shall be upon a more scientific and more comprehensive basis than that at present in use. He believes that the education of the congenitally deaf and of those very deaf children who, by reason of the early age at which they acquired their deafness, have not developed speech, should be commenced at a much earlier age than is now the general rule, in order that they may receive that physiological, in contradistinction to pedagogical, training to which they have as much right as the normal hearing child.

Trypanosomiasis.—F. W. Mott reports the negative results in the examination of the central nervous system in a case of cured human trypanosomiasis.

Salvarsan.—C. F. Marshall believes that in the present state of knowledge there is no drug which can replace mercury in the treatment of syphilis. Although salvarsan causes rapid healing of certain syphilitic lesions, this effect is not constant and is often only temporary. There is no proof that an abortive cure of syphilis can be realized by this drug. If salvarsan is indicated at all in the treatment of syphilis it is chiefly in those cases which are not influenced by mercury, but such cases are rare. Moreover, some cases resist the action of both drugs. The administration of salvarsan is attended with many risks and dangers.

Assimilation of Albumin.—S. A. Arany states that certain processes of assimilation are dependent upon the presence, or rather upon the activity of bacteria, as is proved by Schottelius's experiment, who found that chickens put upon sterilized food did not develop and soon succumbed, whereas if bacteria were added to their food they soon recovered and prospered. Another striking proof of the action of bacteria upon assimilation is afforded by the researches of Ellenberger, who discovered that boiled or filtered intestinal juice of the horse lost its ability of dissolving cellulose.

Multiple Vaccination.—J. D. Staple states that if a child is vaccinated in only one place there is less likelihood of the operation being successful than if this is performed in the orthodox number of places.

The Differential Diagnosis in Cases of Albuminuria. H. French.
Clinical Observations on the Use of Digitalis in Heart Disease and Dropsy, with Filbrillation of the Auricles (Nodal Rhythm). J. D. Windle.
Two Cases of Death from Postanesthetic Acid Intoxication. G. Brown.
Radium in Cancer. C. J. Morton.
Curative Influence of Roentgen Rays in Malaria. B. Skinner and H. W. Carson.
Thyroid Extract in Carcinoma. E. H. Jones.
A Note on "Sensory Tetany," "Vasomotor Tetany," Acroparesthesia, and Raynaud's Symptoms. F. P. Weber.
Operations for Stone in the Male Bladder. W. F. Haslam.

Differential Diagnosis in Albuminuria.—H. French discusses the subject under the following heads: A. Albuminuria with renal tube casts, including the various forms of Bright's disease, the nephritis of pregnancy, chronic ascending nephritis, the result of obstruction to urinary outflow or of irritation of the pelvis of the kidney, lardaceous disease of the kidneys, infection of the kidneys.

thrombosis of the inferior vena cava, and new growths of the kidney. B. Albuminuria with renal tube casts and with pus. C. Albuminuria without tube casts: 1, febrile conditions; 2, heart failure conditions, and physiological albuminuria.

Digitalis in Heart Disease.—J. D. Windle states that it has always been recognized that benefit from the administration of digitalis in cases of severe heart failure is variable, even when classical indications for its use are present. In some patients improvement is rapid and maintained—the heart decreases in size and dropsy quickly disappears; in others its power for good is limited—improvement occurs to a certain extent, and then comes to a standstill; in others again, particularly cases of mitral stenosis with regular pulse, and those resulting from arterial disease, digitalis is often impotent or even harmful—the heart continues to dilate, and dropsy increases under its use.

Postanesthetic Acid Intoxication.—G. Brown reports two cases of this condition. He notes that acetone is present in the urine of patients who have been anesthetized. In order to minimize this possibility the prophylactic feeding with glucose has been recommended.

Radium in Cancer.—C. J. Morton states that at present the position of radium therapy seems to be that while it is of undoubted value in many cases, its chief function is in aiding and not in excluding the other recognized methods of treatment. Until it can be proved that relapse and metastasis are not more common after regression from radium than after excision, the method must be reserved for those cases in which operation is contraindicated and for recurrences.

X-Rays in Malaria.—B. Skinner and H. W. Carson report that their experience has been that the application of *x*-rays in cases of malarial fever relieves splenic pain and reduces recent engorgement; that the temperature falls and does not usually rise again, and that recovery is not attended by the anemia usually present in cases treated with quinine. They have not had to fall back upon quinine in cases treated by the *x*-rays, while they have had cases which resisted quinine and yielded promptly to the rays (quinine being discontinued).

Thyroid Extract in Carcinoma.—E. H. Jones reports a case of multiple carcinoma of the skin and subcutaneous tissue in which the growths disappeared entirely under the administration of thyroid extract.

Sensory Tetany.—F. P. Weber states that the groups of symptoms described as tetany, acroparesthesia, and Raynaud's disease overlap each other, and that cases occur in which one symptom group becomes merged with one or both of the others. Tetany may be preceded or accompanied (or, in mild attacks, replaced) by numbness and tingling in the hands and feet (acroparesthesia), and the motor symptoms of tetany may be regarded as the motor analogue of the sensory symptoms described as acroparesthesia, and of the vasomotor phenomena known as Raynaud's disease. The latter symptom group, according to this view, might almost be termed "vasomotor tetany," just as acroparesthesia might be termed "sensory" tetany.

Operations for Vesical Calculi.—By W. F. Haslam. See abstracts of articles in the *Lancet* February 25, 1911.

Berliner klinische Wochenschrift.

February 20, 1911.

Gastric Ulcer and Pulmonary Tuberculosis.—Stiller of Budapest, after discussing the numerous hypothetical local lesions in the gastric mucosa which may pave the way for peptic ulcers, comes to the alleged rôle of a tuberculous substratum. According to Arloing, Kodon and other writers, gastric ulcer is a paratuberculous affection, due to the tuberculous toxins produced from a latent focus. In other words, there is produced in the gastric mucosa an analogue of lupus erythematosus of the skin, which readily ulcerates. The author believes in the frequent association of the two conditions. Gastric ulcer very often occurs in children of tuberculous ascendants, and subjects with gastric ulcer often beget tuberculous children. In addition to paratuberculosis, manifest structural tuberculosis is not infrequently associated with ulcer. Nearly 20 per cent. of ulcer cases die of phthisis. The author brings his habitus asthenicus doctrine into the causation of gastric ulcer, just as it is also concerned in the predisposition to tuberculosis. His asthenics suffer from enteroptosis, and the majority of gastric ulcer patients suffer from the latter. Hyperchlorhydria must be present if a chronic ulceration is to be set up. The ulcer also occurs by preference in the anemic and chlorotic. All these elements help to make up the asthenic habit, which is the strongest factor in the predisposition to tuberculosis. In individuals with the asthenic constitution, hardly any organ is immune. The subject may come into the world with malformations of the heart and generative organs. On the other hand such subject may be protected largely from metabolic diseases, and from arteriosclerosis and nephritis. The so-called dyspepsia of tuberculous subjects is practically a congenital condition, inseparable from the asthenic habit. Neurasthenia, in so far as it is constitutional, is the nervous expression of this same habit. Gastroptosis implies gastric atony, hypersecretion, hyperchlorhydria. Koch's bacillus seeks for its host this type of congenitally inferior organism, and many kinds of purely local pulmonary lesions serve further to invite it. The author repudiates the idea that subjects with paralytic thorax, etc., are necessarily tuberculous. He sees the contrary every day. Apparently he regards the common predispositions to gastric ulcer and phthisis pulmonum as quite sufficient to explain their coincidence and causal relationship. Nothing in his article appears to show that he regards gastric ulcer as a form of paratuberculosis.

Relationship of Acari to Tumor Formation.—Saul gives credit to Borrel for first calling the attention of cancer research men to the possible rôle of ticks in the genesis of tumors. This element can evidently play no rôle in the formation of tumors of embryonal origin, nor is there and evidence yet to connect it with malignant growths. Nevertheless ticks secrete enzymes capable of setting up tumor formation in both man and animals. These enzymes cause proliferation of individual cells, which tendency is handed down to succeeding cellular generations. The result is a circumscribed hypertrophy. In the rat ticks are able to cause papillomatous formations sufficient to cause death from cachexia. The article is brief and sketchy, intended only for record. The complete paper will follow in time.

Experimental Cholelithiasis.—Klinkert followed the technique of several earlier investigators in this field by placing silk loops in the unopened gall-gladder of rabbits and then injecting virulent typhoid cultures intravenously. In three out of nine cases he obtained positive results—concrements formed about the silk or on the wall of the gall-bladder. These concrements contained no cholesterin and were composed only of pigment and organic matter. The author has found similar concrements in the human subject at autopsy. It seems probable that such formations furnish the nuclei for future deposits of cholesterin.

Münchener medizinische Wochenschrift.

February 21, 1911.

Salvarsan in Yaws.—Strong reports the most flattering results of the treatment of frambœsia with 606 in the Philippines. He leaves the question open as to whether these results form a document of the identity of yaws

and syphilis, yet insists that salvarsan is an ideal specific for the former. After a single injection the worst lesions undergo resolution in from ten to twenty days. The absorption of large granulomata is almost miraculous. Even deep losses of substances heal within the first month. Nothing in the healing art is more striking than the power of this remedy over the disease in question. Thus far the author has had to inject but once, and no relapse has yet been recorded. The spirochetes naturally vanish as the cure progresses. No untoward effects of the injections have been noticed.

Cancer Statistics in Bavaria for 1909.—Theilhaber, as a result of study of cancer records, sums up such results as may throw light on the etiology of the disease. Thus rectal cancer is especially common in government clerks, who are already known to be predisposed to hemorrhoids by reason of their sedentary life and posture. Others who lead a life favoring pelvic congestion are also well represented. Aside from the preceding, rectal cancer is not known to attack special classes of individuals. Gastric cancer is a disease of the poor—peasants, weavers, wood choppers and day laborers. The higher stations of life are attacked more infrequently. Cancer of the face attacks those who live in the open. The very large number of elderly peasants who suffer from cancer of the stomach lends support to the belief that the spread of carcinoma is not synchronous with advances in culture.

Trichobezoar in the Stomach; Gastrotomy.—Up to 1909 there were records of forty-five cases of hair tumors in the gastroenteric tract, of which number twenty-one had been removed by gastrotomy. Kampmann, a gastroenterologist of Strassburg, has added one case to this number. The cases operated upon—all in females—ended in recovery. The non-operated cases tended to end fatally through asthenia or perforation—peritonitis. So unusual an affection, suggestive at the outset of hysteria or stimulation, deserves especial consideration. Patient was a school girl aged ten, who vomited frequently between meals. She had a good appetite yet remained thin. There was a history of a bad habit dating from the first year of life, to wit, the swallowing of hairs or wool from any accessible source. This habit had evidently persisted for years. The patient seemed healthy, but was easily excitable and poorly nourished. Thoracic organs normal. A tumor was palpable in the stomach, which responded to the special tests for a trichoma. A radiograph was taken, the stomach having been filled with a bismuth-carbonate suspension; and the diagnosis of a foreign body was thereby assured. Gastrotomy gave exit to the hair mass. Patient made prompt recovery from the operation and gained weight enormously as a result.

February 23, 1911.

Non-Occurrence of the Bacilli of Bovine Tuberculosis in Human Sputum.—Möllers regards Koch's dictum that bovine tubercle bacilli cannot cause human pulmonary phthisis as practically proven. Human tuberculosis, the white plague so-called, is virtually a disease of the lungs. The author has examined the sputum of fifty-one consumptives, using the complete technique for excluding or demonstrating the bovine bacillus. He finds in literature enough other complete tests to amount to six hundred and thirty-two cases. Human tubercle bacilli were invariably present in this series, bovine tubercle bacilli invariably absent. It is not denied that bovine bacilli are pathogenic to man, or that they cause certain definite lesions. Their rôle, however, is decidedly a subordinate one.

Tuberculous Infection in Childhood.—This article is a sort of supplement to the preceding, both representing work done at the Institue for Infectious Diseases in Berlin. Rothe, the author, finds that in about twenty per cent. of all cases of tuberculosis in childhood the bronchial and mesenteric glands are involved. It does not appear that these children are especially exposed to intestinal infection. On the contrary, the bacilli tend to center the organism through the lungs, as is the case with adults. In regard to the infecting bacillus, all the facts show that this is practically the germ of human tuberculosis. It is freely admitted, however, that in a single case of bronchial gland tuberculosis the perlsucht bacillus was undoubtedly the exciting cause. As one hundred cases were studied, the bovine bacillus was the cause of but one per cent. of all cases.

Significance of the Manchurian Plague for Europe.—Trautmann refers to the untrustworthy accounts of the daily press, and the lack of expert testimony, in respect to menace of a plague visitation in Europe. The plague in question differs from all similar afflictions in that it is primarily a disease of certain lower animals, which nevertheless is extremely pathogenic and fatal to man. It may, however, impose itself as a human plague; that is to say, it may assume such a form (pneumonia) as to be transmitted from man to man without the further mediation of the rodent mammals which it first attacks. In this form it follows the lines of travel on both land and sea. The opening of the Trans-Siberian railway has therefore made it possible to transmit such an affection to Europe in a very short space of time. The sanitary precautions in Eastern Europe are not such as to win the confidence of Germany. A comparison is naturally suggested between the menace of plague and that of cholera. But there is no just comparison to be entertained, for we know as yet nothing at all to indicate that plague carriers exist, *i.e.* apparently healthy men who carry virulent germs. We know that cholera carriers do exist, and that they constitute the chief menace to others. Few survive the plague, but these few in theory constitute a menace as long as their lesions (bubo, pneumonia) are unresolved Plague germs do not enter the drinking water; and generally speaking they are not a hardy germ like the cholera vibrio, which can survive winter's cold in river water. They are readily destroyed by dry heat and ordinary disinfectants. In order to flourish they require moisture and a proper pabulum. The chief danger in respect to transmission by fomites seems to be wholly in the presence of fleas and other insects. It therefore seems that fear of transmission along the Siberian railway is not well founded. The danger of marine transmission, while possibly greater, is antagonized by the sanitary laws which are enforced in the seaports. Neither the rodents nor the fleas which are indigenous in Germany are of the sort which has been accused of transmitting plague. In Hamburg, the author's station, typical cases of plague have been seen in past years. A case is cited which showed plague bacilli in the stool for a few days. The patient recovered and the diagnosis was naturally in some doubt. Incoming ships have sometimes carried both rats and fleas of the sort which transmit plague; and plague-accused ships have been held in quarantine, but with hardly an exception no cases of plague have developed on shipboard.

Staining of the Urine by Criogenin.—Fernández y Benitez describes a discoloration of the urine similar to the one produced by the bile pigments, but due to the ingestion of criogenin. The detection of the drug in the urine is made by means of a reagent composed of a nitric acid solution of ammonium molybdate and another of sodium phosphate; the sediment is dissolved in sodium solution, desiccated and redissolved in nitric acid solution. The reaction consists in a bluish-green tinge in the urine thus treated.—*Crónica Médico-Quirúrgica de la Habana.*

Book Reviews.

THE JEWS: A STUDY OF RACE AND ENVIRONMENT. By MAURICE FISHBERG, Fellow of the New York Academy of Sciences; Member of the American Ethnological Society; The American Association for the Advancement of Science; The American Anthropological Association, etc. Price, $1.50. London: The Walter Scott Publishing Co., Ltd.; New York: imported by Charles Scribner's Sons, 1911.

ALTHOUGH the Jews have for a great many years aroused the interest of scientific writers, this book represents the first attempt made in the English language to delineate a complete ethnic picture of this remarkable people. It is quite fitting that the task of writing this book should have fallen to the lot of a medical man, who has abundant opportunities of observing the physical and mental characteristics of this people, and it is particularly fortunate that Fishberg has undertaken the labor of completing the studies along this line for which he is already well known. The greater part of our knowledge of the characteristics of the Jews is tinctured with the excessive adulation of their admirers or the senseless scorn of their detractors. In the spirit of an impartial observer the author has succeeded in presenting a comprehensive study of the racial characteristics of the Jews. His conclusions on certain fundamental problems associated with the present status and the destiny of the race are in striking contrast to most views on this subject promulgated by lay and pseudo-scientific writers. From an analysis of anthropometric measurements of Jews made in many different parts of the world, it is concluded that they do not constitute a homogeneous race, but have widely different characteristics, depending upon the country in which they are domiciled. There are almost as many different types of Jews as there are countries, each of which type betrays in head-form, stature, and color of hair and eyes a close resemblance to that of the people among whom the Jews have been living for many generations. The inference is drawn that the so-called ethnic purity of the Jews is a myth; that these people have in the past largely intermarried with and converted many of the people among whom they had taken up their abode. This intermixture of the Semite with Aryan and Slav contradicts the popular notion of the racial exclusiveness of the Jews: the restraints of dietetic and other religious regulations, and the artificial isolation imposed upon this people during centuries of persecution, have not prevented a close amalgamation with other races. It is further shown that at the present time in those countries in which the social and political restrictions against the Jews have been removed there is a growing tendency for these people to intermarry with other races. In Germany from 1900 to 1908 one-fifth of all Jewish marriages were contracted with Christians. According to the author this is an indication that the social isolation of the Jew is coming to an end, and that in the near future all the real and alleged differences between Jews and Christians will completely disappear in progressive communities. As regards the demographic phenomena presented by the Jews it is noted that wherever they are isolated by hostile legislation, and as a result of which they are on a low economic and intellectual standard, their birth-rates and marriage-rates are high. They increase in spite of the persistent efforts of their persecutors. On the other hand, in countries in which they are permitted to attain a higher social and economic level their marriage-rates and birth-rates are low. In this respect they react similarly to civilizing influences as do other people. In the chapters devoted to the subject of the pathological characteristics of the Jews there is a great deal that will interest the physician. The lesser liability of the Jews to tuberculosis has been frequently commented upon within recent years, and this is attributed by the author to the fact that they are better adapted to city life and overcrowding by a long sojourn in the Ghetto, and by the process of natural selection those predisposed to tuberculosis have been eliminated. The lower infant mortality is the result of the care bestowed upon her infant by the Jewish mother, the universal practice of breast-feeding, and the fact that the Jewish mother rarely goes out to work after marriage. The author presents the well-known facts that nervous and mental diseases and diabetes are more frequently met with among Jews than among other people, as the result of the psychic trauma to which the Jews have been subjected during eighteen centuries of persecution. It is impossible within the restricted limits of this review to point out all the important conclusions derived from an intensive study of this people: their social and economic conditions in various countries, their education, occupations, criminality, political conditions and social disabilities, and the question of assimilation *versus* Zionism. On all these and on the phases of the subject already discussed the author has succeeded in making a valuable contribution to scientific literature, a contribution remarkable for its originality and freedom from bias. The author has presented his thoughts in a style strikingly clear and free from error, a style whose elegance is in keeping with the breadth of scholarship pervading the entire work.

FRACTURES AND THEIR TREATMENT. By J. HOGARTH PRINGLE, M.B. (Edin.), F.R.C.S. (Eng.). Glasgow, London: Henry Frowde, Oxford University Press, Hodder & Stoughton, 1910.

IT might seem that a new work on fractures, issuing from either side of the Atlantic, was superfluous, and that, even with the advent of the use of the *x*-rays and admitting that it is indispensable in the diagnosis of fractures in general (not of every fracture), there yet could not be enough new in methods of either diagnosis or treatment to make the rewriting of the whole subject fresh or needful to the average American surgeon. The author calls the subject (paradoxically) a "comparatively new one," by virtue of two factors which, he explains, led to his writing the book—the advent of Röntgen's discovery of the *x*-rays and the development of insurance of workmen against injuries. The influence of the latter was apparently felt from a recent English law, the Workman's Compensation Act, which has little interest beyond the principle of employer's liability for American readers; and the chapter on it, with tables of relative indemnity values for injuries, will find but limited use here. But, for all this, the book has, on reading, a renewed interest and many excellencies. A most commendable practice is to introduce the topic of a given bone by mentioning its ossification centers. We think that among practitioners the consideration of this development of bone is not given, in fractures, prominence enough and that familiarity with the centers and the time of their merging into one bone is not overcultivated, even among orthopedists. Those who practise pediatrics, as specialists or not, can profit by this convenient association of ossification centers of a bone with its fractures. Under Joint Fractures emphasis is well put on avoiding too long immobilization with subsequent forced breaking of adhesions. The treatment by leaving the fragments mobile and using massage, advocated by Lucas-Championnière, is given some prominence and a modified advocacy—*i.e.* in ankle and wrist-joint and some shoulder and knee-joint fractures, but not in fractures into elbow-joint, nor of femur or humerus, or both tibia and fibula. The chapter on fractures of the vertebræ has diagnostic diagrams on sensory distribution. One good feature is the bibliography arranged under subdivisions of subjects. As this is very largely German and English literature, it may serve an American searcher well and supplement what references would be more apt to come to his hand. The illustrations and diagrams are mainly practical (as on apparatus, adjustments, etc.), rather than simply of cases or radiograms. The book-making is needlessly cumbersome. American scientific readers do not want in a book heavy, calendered paper nor bulk greater than a clear type (and helpful illustrations) demands.

THE PRACTICAL MEDICINE SERIES. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of GUSTAVUS P. HEAD, M.D., Professor of Laryngology aand Rhinology, Chicago Post-Graduate Medical School; CHARLES L. MIX, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. Volume VII. PEDIATRICS. Edited by ISAAC A. ABT, M.D., Clinical Professor of Pediatrics, Northwestern University Medical School. With the Collaboration of MAY MICHAEL, M.D. ORTHOPEDIC SURGERY. Edited by JOHN RIDLON, A.M., M.D., Professor of Orthopedic Surgery, Rush Medical College. With the collaboration of CHARLES A. PARKER, M.D. Series 1910. Chicago: The Year-Book Publishers.

THREE-QUARTERS of this small volume deals with the advances in pediatrics during the past year. Among the infectious diseases is described an epidemic (75 cases) of an exanthematous disease in which the diagnosis was not clear. It resembled rubella in some respects and scarlet fever in others. J. W. Watson, the writer, believes it to be a new disease, and in want of a better name calls it the "Fifth Disease." The section devoted to "Orthopedic Surgery" covers briefly the work done in that specialty during the previous year.

Society Reports.

SEVENTH ANNUAL CONFERENCE ON MEDICAL EDUCATION OF THE AMERICAN MEDICAL ASSOCIATION.

Held at Chicago, Illinois, March 1, 1911.

The Chairman, Dr. Arthur Dean Bevan, Presiding.

The chairman in calling the conference to order said, first, that medicine was to-day a science just as chemistry was a science and physics was a science. The art of medicine to-day rested as firmly upon a scientific basis as did the practical application of chemistry and engineering, and as there could be but one science in chemistry so from now on there could be but one science of medicine. The fads and pathies that formerly existed under the old empirical practice of medicine became impossible in the light of modern scientific medicine. A thorough training in the sciences upon which medicine was based was essential in the modern medical curriculum, and a thorough familiarity with disease processes in the living patient must be mastered before the student was permitted to begin independent practice. First, after graduating from high school at least one year of training in physics, chemistry and biology; two years in the science of anatomy, physiology, pharmacology and pathology; two years in the study of medicine, surgery and obstetrics and the specialties, with the opportunity of studying those subjects in the dispensary and hospital, and lastly a year's practical training as an interne in a hospital in which the student was a part of the medical machine which was responsible for the proper care of the patients.

Progress and Needs in Medical Education.—Dr. N. P. Colwell, Chicago, Secretary of the Council, presented a report on this subject and stated that since 1904 there had been a positive decrease in the number of colleges until now the number had been reduced to 129. Of the 44 colleges closed since 1907, 20 colleges were closed outright and 24 by merging with others. Of the 20 which became extinct 16 had been graded in Class C by the Council on Medical Education. Since 1904 there had also been a decided improvement in the standards of admission. Until 1904 only three or 1.9 per cent. of all medical colleges were requiring for admission more than a high school education, but now 41 or 31.8 per cent. (nearly one-third) of all colleges were requiring for admission one or more years of collegiate work, and the teaching of medicine as a whole had been placed more largely upon a university basis. He referred to other improvements, the improvements that were still needed, and said that the educational safeguards were still faulty. The low standard colleges referred to could exist only in states where the laws regulating the practice of medicine were inadequate or were not enforced. The solution of many of the problems of medical education rested in the hands of the State licensing boards, and doubtless would be solved by them if they were given a fair chance. As a rule, the board was too closely connected with politics and in some States the members were appointed largely for political reasons and were liable to be changed with every turn of politics. He said there should be one portal to the practice of medicine. Not only should there be but one board in each State, but there should be a single educational standard fixed with which every applicant for a license to treat the sick by whatever means or methods should comply.

Entrance Examinations.—Dr. Thomas S. Fiske, of New York City, enumerated the following manifest advantages of the examinations held by the college entrance examination board; first, that they were uniform in subject matter. Second, that they were uniformly administered. Third, that they were held at many points to meet the convenience of students at one and at the same time. Fourth, that they represented the cooperative effort of a group of colleges, no one of which thereby surrendered its individuality. Fifth, that they represented the cooperation of colleges and secondary schools in respect to a matter of vital importance to both. Sixth, that by reason of their uniformity they aided greatly the work of the secondary schools. Seventh, that they tended to effect a marked saving of time, money, and effort in administering college admission requirements.

Five-Year Medical Course.—Dr. J. G. Adami, McGill University, Montreal, said regarding the five-year course in medicine, now in operation in the leading Canadian schools, that it was not deemed essential all the medical schools of the continent should adopt such a course. There might be other medical schools having a similar environment, however, which might obtain the best results educationally by establishing a similar course. Briefly, the objects in the development of the curriculum at McGill had been, first, to give a sound course in the preliminary science subjects; second, to make the courses from the first to the fifth year as practical as possible; third, to observe a natural sequence in the various courses, and, fourth, to give the maximum of hospital instruction with the freest employment in the wards and of bedside instruction.

Equipment and Instruction of the Laboratory Years.—Dr. E. P. Lyon, of St. Louis, stated that the scientific instruction must be in the hands of professional scientists, not practitioners of medicine. They must be provided with proper laboratories for teaching and research with equipment, materials, libraries and assistants. Anything less than this provision was to disregard the model which the school was trying to realize, namely, the good doctor. The laboratory work should be conducted by the professors and not by cheap assistants. If the right men were chosen for heads of departments the choice of specific equipment might be left to them. The State Board would do well to insist that the colleges have trained instructors rather than publish lists of required equipment which might or might not be used. The three powers of good observation, experimentation and judgment were necessary for the technical work of the physician. But on account of his intimate relation to the people he needed many other psychological traits which might be summed up as character. The medical school could do little by precept, but much by example. The medical teachers should be men of character and culture.

Instruction and Equipment of the Clinical Years.—Dr. George Blumer, Yale University, stated that the problem of teaching in clinical years was a threefold one; training in the fundamental principles of medicine, surgery and obstetrics, practical training in physical and clinical diagnosis, and surgical technique. There was opportunity to apply the principles of technique by actual contact with patients. He made a comparison of clinical and didactic teaching as methods of imparting fundamental training. He pointed out the advantages and disadvantages, and said the proportion of such was determined by local conditions. There was a tendency to overemphasize didactic teaching. Technical training in clinical and physical diagnosis must be by laboratory methods. Didactic methods were out of place. He spoke of the advantages of the use of living animals in teaching surgical technique. Contact of students with individual patients was the keynote of the fourth year instruction. A system of clinical clerks was desirable. Students should do most of the work in clinics. He referred to the equipment necessary, and spoke of laboratories with microscopic and necessary apparatus to teach students. The dispensary especially should be equipped for teaching with abundant material. The hospital especially should be equipped for teaching under competent medical school control. The greatest

problem at present was lack of proper endowment, namely, properly paid and trained men in clinical years. There was a lack of absolute control of hospitals by medical schools.

Subjects Included in the Two Years of College Work Required for Admission to Medical Colleges.—Dr. Charles R. Bardeen, Madison, Wisconsin, said that during the two years of college work required by the majority of medical colleges which could afford to maintain high preliminary standards about half the time should be devoted to physics, chemistry, biology and English. The other half of the time should be divided between the study of foreign languages and one or more non-technical studies such as art, history, economics, civics, mathematics, and philosophy. The aim of this preliminary college work should be to produce breadth of view as well as to give some understanding of scientific knowledge and methods.

State License Examination.—Dr. Horace G. Norton, swers given from a full understanding of the subject. The primary object of the examination was to determine whether the applicant had a competent practical knowledge of the science of medicine, and that he was not giving quiz compend answers. Every experienced examiner could, he thought, distinguish compend answers from answers given from a full understanding of the subject. The examination of the student included his academic qualifications, and the reliability of the medical school from which he graduated. He thought that written examinations were good so far as they went, but they must be supplemented by other and practical tests. In his State the present law directed a written examination. He hoped this winter that a better medical law would be passed allowing the institution of a practical examination. He had no personal knowledge of examinations in other countries, but would be glad to hear from those who had. What practical examinations should be required without too much trouble and expense? He was sure that the bedside examination in a hospital was impractical and unnecessary because of the time consumed. He did believe, however, that refraction, blood examination, urinary examination, recognition of pathological and bacterial slides, a showing of ability to use a microscope, and the possible detection of heart and lung lesions and chemical reactions were practical. He then described the best method of preventing impersonation.

Interstate Reciprocity.—Dr. W. T. Gott, Indianapolis, Indiana, stated that in recognition of a strong demand in the profession some States entered into reciprocal agreements as early as 1901, and that at the present time the majority of States had such agreements with certain other States. Reciprocity in medical licensure, if conscientiously administered, had a favorable influence on educational standards. State practice acts were not apt to be weakened or the standards lowered, since that would endanger the reciprocal relations with other States. Medical colleges also were urged to keep their standards high, since their students were thereby made eligible to registration through reciprocity in a larger number of States. As long as cults in the healing art existed, according to the speaker's judgment, it was a serious mistake to provide for each a separate board of medical examiners. The administration of such boards was consciously or unconsciously influenced by bias and unnecessary temptation was put in the hands of such boards to be lax in passing on the credentials of applicants of their own system of practice. The speaker further believed that credentials issued by a board composed entirely of representatives of one school or system of practice should not be acceptable for a certificate through reciprocity, and that such a ruling would have a salutary effect in upholding the standard of educational qualifications throughout the country.

Dr. Frank B. Hiller, Jefferson City, Missouri, read a paper entitled "Valuation of Credentials."

Dr. James B. Herrick, of Chicago, followed with a paper entitled "Educational Functions of Hospitals."

At the joint conference on Medical Practice Acts several papers were read bearing on medical practice acts and the public, the attitude of the judiciary in the enforcement of medical practice acts, and what should be the attitude of the State toward the practice of medicine. The subjects of the regulation of the practice of medicine for the public good and the administrative duties of the State Boards of Medical Examiners were discussed.

At the Seventh Annual Conference on Medical Legislation the committee on resolutions submitted the following report, which was unanimously adopted:

Whereas, the Committee on Carroll Memorial has completed its work in a manner highly satisfactory to all concerned,

Resolved, that the final report of the committee be accepted and the committee discharged, and be it further,

Resolved, that the Committee recommends that the cordial thanks of the Conference and of the Association be extended to Major Ireland and his committee for the efficient manner in which they have accomplished their work.

Resolved, that the thanks of the Conference be extended to Drs. Halsey, Gay, and Bristow for their individual efforts in the consideration of medical expert testimony and that this committee be discharged, and be it further,

Resolved, that the Council on Health and Public Instruction be requested to establish a standing committee to give this matter thorough consideration and if possible to confer with a committee of the American Bar Association.

Resolved, that the Seventh Annual Conference of the American Medical Association on Medical Education and Medical Legislation deplores the action of Columbia University of New York in establishing a course of study in optometry, for the reason that opticians have never succeeded in founding an official school of optics or optometry, but have relied on the recognition or legalization of the word optometry to make them a profession, and for the further reason that the existence of such course at Columbia University has this year been used in many States as the chief argument for the further enactment of optometry laws, which are designed to permit opticians to practice medicine in a limited degree, and be it further

Resolved, that a copy of these resolutions be transmitted by the secretary of this Conference to the President of Columbia University of New York.

Resolved, that this Conference reaffirm its endorsement of the model bill on vital statistics and express its appreciation of the interest shown by Hon. E. D. Durand, Director of the Census, and by Dr. Cressy L. Wilbur, Chief of the Division of Vital Statistics, in promoting the adoption of uniform vital statistic laws in the various States, and that the secretary be instructed to furnish a copy of these resolutions to the above-mentioned gentlemen.

ST. JOHN'S GUILD ALUMNI ASSOCIATION.

First Regular Meeting Held November 16, 1910.

Medwin Leale, M.D., President, in the Chair.

President's Address.—Dr. Medwin Leale, the President, in an opening address said that the Association of the Alumni of St. John's Guild Hospitals for Children was organized last May with three distinct objects: first for the maintenance of interest in the work of the St. John's Guild Hospitals among the profession and laity; second, for the consideration and discussion of matter pertaining to the hygiene and diseases of infants and children; and third, for the establishment of friendly relations among its members. In regard to the first reason for the society's existence, after all, it was those who had

been intimately connected with the work of this distinctly eleemosynary institution who were best qualified to diffuse interests in its work and the members would be poor sons of the parent institution if they did not ever keep this in mind. The second object, the scientific one, brought forward the wish that from one or more of the members might emanate something of real scientific value, something which might be of benefit to the little sick ones. It was the speaker's sincere hope that the third object would indeed cultivate among the members the friendliest relations and that it might make them mutually helpful. If these three objects were achieved the establishment of the society would not have been in vain.

Work of St. John's Guild.—Dr. W. Morgan Hartshorn read a paper upon the work of the Guild during the past summer. He reported that during the last five years the Seaside Hospital had made rapid advancement financially and in the recognition as a prominent factor in the reduction of infant mortality in New York City. During the season of 1910 over 45,000 patients were carried upon the boat and 2,400 were admitted to the Seaside Hospital. In cases treated there were over five times as many suffering from diseases of the intestinal tracts as from other conditions. Although many were admitted *in extremis*, yet the deaths numbered only 40 during the summer. Additional land had been acquired, so that the institution now controlled 15 acres. During the past summer, at an expense of $43,000, two of the new concrete wings had been completed. The outer easterly wing contained 32 beds for babies and was to be used as an overflow or convalescent ward. The other new wing contained 24 beds for mothers and babies and 10 for children. These buildings were equipped with all modern sanitary improvements. Two similar wings upon the other side would be built as soon as funds were secured. Eventually they hoped to have eight new pavilions. The Guild had also purchased land along the beach 100 feet, including the greater part of the cedar grove. The feeding cases were the most difficult to handle, but responded fairly well to modified milk and to some of the proprietary foods. Last summer Soy bean flour was introduced and the results showed that owing to its high protein value and to the absence of starch it was useful in selected cases. As a diluent for cow's milk in the form of a gruel made by boiling one tablespoonful with 6 ounces of flour to a quart of water for 15 minutes, it was taken readily by the babies. Of 15 cases fed with Soy bean 10 gained, 2 held their own, and 3 lost.

Sudden Death Following Spinal Puncture for Diagnosis.—Dr. Edward M. Colie reported this case. (See page 487.)

Dr. Philip Smith said that spinal puncture was performed very frequently in their hospital, especially in patients suffering from paresis. The occurrence of a lymphocytosis was strong corroborative evidence that this disease existed and it often served as a differential point in excluding some other conditions. He had not observed any harmful effects following spinal puncture except in two instances. In some cases there was a feeling of dizziness, some nausea, and vomiting, but these symptoms did not persist any length of time and no after-effects remained. In the two cases to which he referred, soon after spinal puncture was performed there was nausea and vomiting, with the occurrence of a stuporous state. The temperature became elevated and marked signs of pulmonary edema preceded death. The first died in about 72 and the second in about 48 hours after the spinal puncture. Autopsy in each case disclosed a tumor affecting one of the hemispheres. The unfavorable symptoms and fatal termination were considered to be due to the sudden lessening of the intracranial pressure.

Dr. W. Morgan Hartshorn said that he recalled a somewhat similar case of brain abscess upon which he had performed the autopsy several years ago. The symptoms, as in Dr. Colie's case, had been misleading and the patient, a boy of 11, had been sent to Johns Hopkins Hospital, where Dr. Cushing had operated to relieve intracranial pressure. The operation had not been successful, however, and the child died. Upon autopsy a large abscess involving the entire temporosphenoidal lobe had been found. The case was interesting in that several diagnoses had been made by a number of physicians.

Dr. Colie said, in closing, that had he known that there was a cerebral tumor present in this case he would not have recommended spinal puncture, for the danger under such circumstances was too well known. Thinking that it was an uncomplicated meningitis he wished to take advantage of the slight doubt remaining, and if it had turned out to be a meningitis of the epidemic form to have at once instituted the serum treatment. He thought, in the light of this case, that it was a safe rule to stop when the pressure stopped. Further, if there should be no apparent increase in the volume of the cerebrospinal fluid and at the same time a patently marked intracranial pressure, it would be best to assume that the drainage from cerebral to spinal meningeal cavities was interrupted.

Multiple and Comminuted Fractures of the Metatarsal Bones in a Child, with Skiagraph.—Dr. Medwin Leale read this paper. (See page 486.)

The Modern Care and Treatment of the Insane.—Dr. Philip Smith of New York City presented this paper. He said that the nature of the insane institution was imperfectly known. The care and treatment of the patient was often looked upon with dread by the relatives of the unfortunate one because of the impressions obtained from the newspapers and other unreliable sources. Very many of the accidents reported were due to pathological changes in the bones of the patients that made them very friable and liable to serious injury without violence. Also the patient's distorted imagination often caused false reports to be circulated. The idea that mental diseases are the only ones treated in the hospital should be corrected for the physician now more than ever tries to remedy all the physical defects liable to affect the patient. During the past two years modifications for admission of patients to insane hospitals had been introduced. Instead of passing through the regular form of commitment, examination by two duly qualified physicians and a complaint to a justice of the supreme court, they could now be received by making a voluntary application to the superintendent of the institution. They had the right to leave at any time after giving five days' notice providing it was safe to the community. At the Manhattan State Hospital the usual routine was as follows: After an inspection the patients were photographed and bathed. A physical and mental examination was then made by the medical staff and a careful history obtained. The patient was then presented at a meeting of the medical staff. These were held three times a week. After observation he was again brought before the staff meeting and a final diagnosis was made. The family physician was invited to these meetings and his cooperation was asked for. Patients on parole reported regularly at the hospital and observations were made. If necessary the patient could return to the hospital without the formality of commitment. If the relatives of the patient became insistent and refused to listen to advice, the question of discharge was vested in the superintendent of the hospital, or on his refusal, in the courts. Under the law a bond was given to assure proper care in the future. An after-care society had been formed under the control of the Lunacy Commission whose scope was to keep the patient under observation and to provide work and a home for him if necessary.

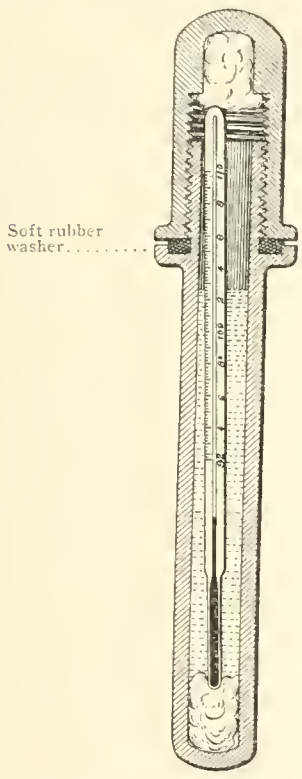
New Instruments.

AN AUTO-ASEPTIC THERMOMETER CASE.

By EMILE BERLINER,

WASHINGTON, D. C.

Many infections may take place by the infective material becoming lodged on the mucous membranes of the mouth, larynx, pharynx, or in the nasal passages. Notable transmissions of disease germs of virus from one individual to another are observed in the spread of diphtheria, laryngitis, bronchitis, tuberculosis, and infantile paralysis. It is a fact that practically all the patients of a doctor are brought into more or less intimate contact with one another by the clinical thermometer. Hence the great necessity of preventing infection from taking place by way of clinical thermometers which are not sufficiently disinfected after taking the temperature of a sick person, either in incipient cases or in such as are fully developed. It is not inconceivable that



when the mind of a physician is concentrated on a case of sickness he will often forget to observe that care in disinfecting his thermometer which modern bacterial research points out as necessary for preventing the spread of contagion.

At a recent meeting of the Association for the Prevention of Tuberculosis in Washington, D. C., the writer presented a simple improvement in tubes or cases for clinical thermometers which makes possible an automatic and at the same time most thorough disinfection of the thermometer after each use. The improvement consists in a soft rubber, or leather, washer placed where the top of the tube or case is screwed to its body. This washer seals the case and renders it watertight.

Solutions of formaldehyde, carbolic acid, bichloride of mercury, peroxide of hydrogen, or other powerful disinfectants are poured into the tube, filling it, say, one-half. When required for use the thermometer is rinsed off in water, wiped dry, and the temperature is taken; this rinsing is repeated afterward before it is put back into the case. A single shake will then cover the thermometer with the antiseptic fluid and disinfect it.

The invention is obviously a perfect one, and the only question to be decided is about the kind of antiseptic fluid which should be used. This was brought out in the discussion which followed my presentation and which was participated in by General George M. Sternberg, Dr. George M. Kober, Dr. E. C. Schroeder, Dr. G. Lloyd Magruder, and Dr. W. C. Gwynn, all of whom agreed upon the undoubted value of the conception. Dr. Schroeder favored a 5 per cent. carbolic acid solution, and Dr. Kober has already undertaken to have experiments made at the Hospital Laboratory of Georgetown University in order to settle the question. The illustration accompanying this article hardly needs any further description than that already given. The improvement is so simple that every conscientious physician will undoubtedly secure such an auto-aseptic case as soon as manufacturers place them on the market.

1438 Columbia Road.

Medicolegal Notes.

A Medical Expert is Not Necessarily an Expert in Insurance Law.—In an action on a life policy a question to a physician as to whether, taking into consideration the condition in which he found the insured in March, 1901, and what the insured told him about the previous history of the case, the insured would have been insurable in October, 1900, was excluded. While he was an expert in matters pertaining to his profession it was not shown that he was an expert in the law of insurance, so that he could tell, in reference to different physical conditions, when a man would be insurable.—Reagan v. Union Mut. Life Ins. Co., Massachusetts Supreme Court, 92 N. E. 1025.

The Privilege of Confidential Communications Applies in Testamentary Matters.—An offer to show by the medical attendant of the deceased, in a will case, that he had visited her professionally and that from his observations she was in his opinion not of sound mind was rejected under the provisions of section 7304 of the 1905 North Dakota Code. This privilege of secrecy, it was held, is personal with the patient, and applies in testamentary matters, and cannot be waived by the heirs and personal representatives.—Auld v. Cathro, North Dakota Supreme Court, 128 N. W. 1025.

Case of Injury Where Relation of Patient and Physician Held to Exist.—In an action for injuries sustained in a street car accident it was held that the testimony of the company's physician, who was sent to attend those injured in the wreck, as to the plaintiff's condition at the time he treated her in the performance of this duty was properly excluded as being a privileged communication.—Louisville & S. I. Traction Co. v. Snead, Indiana Appellate Court, 93 N. E. 177.

Sufficiency of Registration.—An accusation charged a violation of section 485 of the Georgia Penal Code of 1895 for practising medicine without registering in the office of the clerk of the supreme court of the county where the accused practised. The requirement of the laws is that every person engaged in the practice of medicine within the State of Georgia, before commencing to practise, shall register with the clerk of the superior court of the county wherein he resides and is practising, or intends to commence the practice of medicine. He is not required to register wherever he may practise mdicine. One registration is sufficient in the county where he resides at the time he commences the practice of medicine. The accusation was therefore fatally defective in failing affirmatively to allege that the county in which the accused was charged with having practised medicine without registering was the county wherein he resided.—Jones v. State, Georgia Court of Appeals, 69 S. E. 315.

Indictment for Practising Without License in Missouri Must Allege That Physician Was Not Registered on March 12, 1901.—The Missouri act of March 12, 1901 (Laws 1901, p. 208), §5, provides that any person, except physicians already registered, practising medicine in the State, and any person attempting to treat the sick without first obtaining a license from the State Board,

shall be guilty of a misdemeanor. Act of March 22, 1907, amends this section so as to provide that any person practising medicine in the State, and any person attempting to treat the sick, or representing or advertising himself to be authorized to treat the sick, without a license from the State Board, shall be guilty of a misdemeanor, provided that physicians registered on or prior to March 12, 1901, shall be regarded as registered physicians for the purpose of the act. It was held that the last mentioned proviso was an exception to the enacting clause of the statute, and an information or indictment thereunder which fails to allege that the defendant was not a registered physician on or prior to March 12, 1901, is fatally defective.—State v. Brand (Missouri), 131 S. W. 923.

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading, but it must be with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

Regeneration of Epithelium in Tuberculous Intestinal Ulcers.—R. Amenomiya finds that tuberculous intestinal ulcers may be healed not only by scar formation but to a great degree by the regeneration of the damaged tissue. The process is similar to that which occurs in the case of typhoid ulcers.—*Virchow's Archiv.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended March 10, 1911.

Places.	Date	Cases.	Deaths.

ON THE INJECTION OF DRUGS, ESPECIALLY OF SALVARSAN (EHRLICH) INTO THE LUMBAR MUSCLES.*

By S. J. MELTZER, M.D., LL.D.,

NEW YORK,

FROM THE DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY OF THE ROCKEFELLER INSTITUTE.

The intramuscular injection of drugs is a familiar procedure. It came into practice about thirty years ago, especially for mercurial injections in the treatment of syphilis. It had the meaning of a "deep injection" and was instituted for the purpose of avoiding pain and abscesses. It was not expected that the intramuscular mode of injection would serve to hasten the absorption of the injected drugs; on the contrary, Neumann and Finger[1] asserted that the absorption from the muscles is not as good as from the subcutaneous tissue on account of the paucity of lymphatics. The same view is apparently still held by some clinical writers of the present day. Gennerich, for instance, a valued recent contributor to the therapeutics of salvarsan, says[2] that the subcutaneous application has the advantage over the intramuscular by its more intense action, and he believes that the intramuscular effect is more prolonged.

A few years ago Auer and I[3] published experiments in which it was demonstrated that the absorption, after an intramuscular injection, is by far more rapid than after a subcutaneous one. For reasons which we need not discuss here, we carried out recently another series of similar experiments. In these experiments the absorption of various drugs was studied, but adrenalin was employed most extensively on account of the characteristic rise of blood pressure which this agent produces when it reaches the circulation.

I shall give here only a brief résumé of our chief results; they are as follows: 1. An injection of adrenalin into the lumbar muscles of rabbits causes an immediate rise of blood pressure which is practically not inferior to that of an intravenous injection; a subcutaneous injection causes a very insignificant rise, if any. 2. The duration of the rise of blood pressure after an intralumbar injection is regularly longer than after an intravenous injection. 3. The effects of an injection into the gluteal muscles is inconstant and insignificant; if it causes a rise of blood pressure at all, it is moderate in degree and of short duration.† The experiments with other substances gave essentially similar results.

*Read at the meeting of the New York Academy of Medicine, March 2, 1911.

†A full account of these experiments with illustrative tracings will be found in the March issue of the *Journal of Experimental Medicine.*

We may mention here that Morgenroth[4] found our results to hold good, also for diphtheria antitoxin.

We offer the following explanation for our findings: In the first place the muscle tissue is abundantly provided with blood capillaries, and it is now generally accepted that the absorption of solutions takes place chiefly through these capillaries. Then the lumbar muscles are firmly encased all around in strong inelastic fasciæ, an injection of a quantity of some mass or solution into the dense tissue causes locally an increase of the intramuscular pressure which is then, at least, partly, the means of driving the soluble part of the mass through the wall of the capillaries. In the subcutaneous tissue there is neither an abundance of blood capillaries nor can the local pressure there be easily raised.

The difference in the power of absorption between the gluteal muscles and that of the muscles of the lumbar region depends, we believe, upon some anatomical differences. The sacrospinal muscle presents a large, roundish, compact mass of muscle tissue, consisting of fine muscle bundles, densely packed, with very little connective tissue between. The muscle is wrapped up tightly by strong fasciæ which effectively isolate it from the various adjacent tissues. The gluteal muscles, on the other hand, are made up of flat muscle layers, consisting of coarse muscle bundles. The various bundles, as well as the various muscle strata, are separated by loose connective tissue. The fasciæ envelop the muscles only loosely, and it seems that on the inner side the muscles are not sufficiently isolated, especially not from the loose connective tissue which surrounds the nerves and blood vessels emanating from the pelvis. While an injection into the sacrospinal muscle always remains *intramuscular,* this is not the case with the gluteal muscles, in which the injected solutions can readily escape into the loose connective tissue which is abundantly present within and next to the muscle tissue. The rate of absorption from within this loose areolar tissue probably does not differ much from that of the subcutaneos tissues.

These anatomical differences between the two sets of muscles are very well pronounced also in the human being. On the basis of our experimental observations I offer, in the first place, the suggestion in a general way, *that in medical practice injections of drugs should be made into the lumbar muscles,* especially in cases in which a rapid effective action is urgently needed. However, I wish to discuss here in particular the more specific proposition that *salvarsan (Ehrlich) should be injected into the sacrospinal muscle.*

The administration of salvarsan began its career by injections into the gluteal muscles and probably for no other reason than that mercury, some arsenical preparations and other drugs were usually administered by this method. The unpleasant compli-

cations which appeared in some cases of intragluteal injections made it desirable to administer the new very active drug in some other way. I shall not discuss any of the other methods employed for this purpose. Our experience with the rapid and prolonged absorption of the other substances from the

Fig. 1.

lumbar muscles brought the suggestion to my mind that salvarsan also ought to be injected into these muscles. A further analysis of the unpleasant conditions complicating sometimes the intragluteal injections (excruciating pains, peroneal paralysis, sciatica, thrombosis of the femoral and iliac veins etc.), made it evident that they were the result only of the special anatomical structure and location of the gluteal muscles; the injected mass of the substance escaped into the loose areolar tissue between the muscles and in their proximity, and gravitated toward the lowest and least resistant point and that is the loose connective tissue near the exit of the sciatic nerve. On the other hand, the sacrospinal muscle which contains but little loose connective tissue, and is, as stated before, well encased in complete strong fasciæ, is practically better isolated from its neighborhood than any other muscle in the body. A substance injected into this muscle will remain, if properly done, within this muscle, will have all the advantages of an intramuscular injection, and will in no way affect neighboring organs and tissues. I have, therefore, tested this plan of administration of salvarsan in several cases of syphilis.

I mentioned this method at a medical society in a discussion on Ehrlich's new remedy. Since then it has been employed by several practitioners. Dr. Kakels mentioned it in his paper.[5] I know, however, that some physicians use it in an incorrect manner. In Gottheil's[6] paper it is mentioned that in a few cases the solution of arsenobenzol was injected in the quadratus lumborum. I do not know whether my remarks gave rise to this procedure, but a glance at Fig. 2 may suffice to prove that it is unsafe to inject into that relatively thin muscle. No wonder that in some of the cases in which this method of injection was used "a large tense mass extending down to the front of the abdomen" has been formed. I decided, therefore, to embody here reproductions of the excellent figures from the well-known Atlas of Anatomy of Spalteholz.* They show the exact location and the relations of the sacrospinal muscles, the character of the mass of muscle tissue and the fasciæ which surround it.

The following are a few details which have to be observed in carrying out the intralumbar injection as I suggest it. The patient is lying on the abdomen, the part of the abdomen opposite the lumbar region being supported by a pillow or two. In women, with their normal lordosis, this support is indispensable. As a rule, in this position the sacrospinal muscles are sharply outlined. An imaginary line should be drawn which unites the highest (most cephalic) point of the iliac crest with the third or fourth spinous process. At about the junction of the inner and middle third the needle should be inserted. On Fig. 1 the point of insertion is indicated by a cross. The needle should at first be pushed straight perpendicularly in the ventral direction until the fasciæ is reached. This is in most cases easily recognized by the sudden resistance which the needle meets. After the fascia is penetrated, the point of the needle should now be directed straight forward (toward the head), moderately vertically and very slightly outwards. The needle, which has to be strong and with a fairly wide lumen, should have a length of not less than three inches. With shorter needles the injected solution may in some obese individuals remain outside of the fascia. There is in obese persons sometimes an unsuspected amount of fat between the muscle and the skin.

My personal experience with the intralumbar injection of salvarsan is limited to about a dozen cases in which I administered the remedy myself, carried out at the period before the remedy was for sale. In all instances the patients were under observation of other physicians. Five cases were under the care of Dr. W. H. Luckett in his surgical service at the Harlem Hospital. Of these I had the fullest account. Perhaps Dr. Luckett will report on these cases himself. I shall enter into no details and shall draw my general conclusions with the necessary reserve imposed by the paucity of the observed material.

The curative or healing effect of the remedy when applied by this method was apparently, to say the least, not less prompt than that observed after other methods of administration. Secondary and tertiary manifestations disappeared in a surprisingly short time. For instance, a woman with papulo-macular eruptions over the entire trunk and limbs, and mucous patches in throat and mouth received an injec-

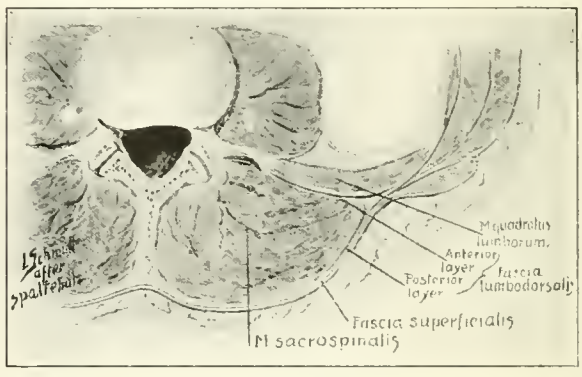

Fig. 2.

tion of 606 in the lumbar region on November 3, and on November 9 it is reported: "Eruption almost entirely disappeared; shows only a 'copper stain.' Throat no longer red and sore." Another woman, pregnant eight months, who had hard, tender nodules on both arms and on one leg, and two specific

*My thanks are due to Mr. L. Schmidt of the Rockefeller Institute for the artistic reproduction.

ulcers on the left leg and the right arm, had an injection of 606 on October 23, and on November 1 the report reads: "Ulcers entirely healed; only a dull stain left," and further: "Baby born December 19, normal, no rash of any kind."

Regarding the Wassermann reaction,* I obtained information only in seven cases. Of these, in six the reaction became negative and in one it remained positive.

In ten out of the twelve cases no palpable reactions followed the intralumbar injection, and among these were some lean people in whom any abnormal infiltration would have easily been discovered. Of the remaining two cases, in one a moderate edematous swelling in the lumbar region followed the injection, which completely disappeared. In this case the patient was very obese and the needle which I had to use was too short. I felt sure soon after the injection that the alkaline suspension of the remedy, which I used in this case, remained, at least to a great extent, outside of the muscle. Regarding the local reaction of the twelfth case I received no information.

Salvarsan was administered in most of our cases as a weak alkaline, fine suspension, and in a few instances alkaline solutions of the remedy were employed.

In eight of the twelve cases the injection of salvarsan caused no pain worth speaking of, neither at the time of injection nor any time later. In one case the patient complained of a good deal of pain and of a heavy weight in the lumbar region. That was the case of the above mentioned very obese patient, who probably received the injection mostly in the subcutaneous tissue. Of two other patients, also obese individuals, it was reported that they complained of some pain in the lumbar region. One of these patients whom I had a chance to examine myself, performed at my request such movements in which the lumbar muscles are actively engaged, with the greatest ease and without evincing any sign of pain. About the second individual I had no definite information, but there was room for the suspicion that the diagnosis of "lumbago"—for domestic reason—required complaining of some pain. The fourth patient, the only thin person who complained of pain during the injection and spasmodically at various times after the injection, while the pain did not seem to interfere with any movements of her body, was a woman of manifestly hysterical type.

Regarding pain, it may therefore be said that when the intralumbar injection was made strictly intramuscular the pains which occurred during, or followed at any time after these injections, were neither in extent nor in character important enough to be considered as a complicating factor.

To recapitulate briefly, in my limited experience the injections of salvarsan strictly into the sacrospinal muscle proved to cause no ill effects, no reactions or infiltrations and not much pain, and exerted an unmistakable beneficial effect.

One of the indispensable requirements of this method is to inject the remedy strictly into the sacrospinal muscle. In lean individuals this is easily carried out. With a full knowledge of the anatomy of the lumbar region and under observation of the above given simple details of the method there should be no difficulty to inject strictly into the muscle, even in obese persons. We may admit, however, that in injecting obese individuals some failures may occur. But even so, no serious effects will follow such failures. The pains and edematous swelling of the lumbar region, which may follow the injection of the remedy into the subcutaneous fat of that region will be, to say the least, not worse than the pains and infiltrations which follow the subcutaneous injections in other regions. On the contrary, I believe that if the preparation and the injection of the remedy is done strictly aseptically the reactions of these deep seated subcutaneous injections in the lumbar region will disappear rapidly without untoward incidents.

Résumé.—The sacrospinal muscle presents anatomically an exceptionally well isolated large compact mass, densely packed with fine muscle bundles. Any solution or suspension injected strictly into this mass will remain there and not affect locally the adjacent tissues. Experimentally it was shown that the absorption from this muscle is superior to that from the gluteal muscles and vastly superior to that from the subcutaneous tissue. Clinically it was established in a limited number of cases of syphilis that salvarsan injected into this muscle exerts a fairly rapid, unmistakably beneficial influence upon secondary and tertiary manifestations of syphilis and upon the Wassermann reaction without causing pain and other ill effects deserving any serious considerations.

It seems to me that the lumbar method of injection deserves a critical trial by careful observers for salvarsan as well as for other drugs.

AN INVESTIGATION OF RECENT OUTBREAKS OF TYPHOID FEVER IN AN ADIRONDACK CAMP, AND THE DISCOVERY OF A TYPHOID CARRIER.*

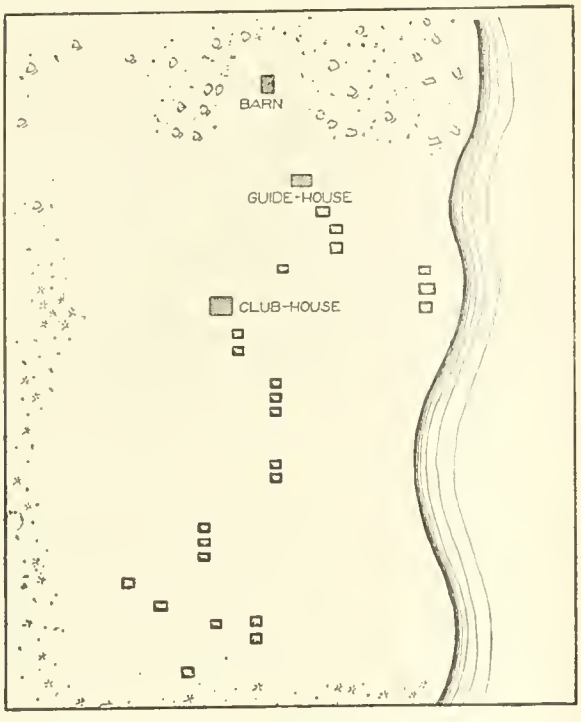
BY CHARLES E. NORTH, M.D.,
NEW YORK.

IN the month of August last the writer was asked to take charge of an investigation into the cause of an outbreak of typhoid fever then occurring in a large summer colony encamped on the borders of one of the lakes in the Adirondack mountains. The outbreak was explosive in character and of such an extent as to cause much alarm and to raise the question whether or not the camp should be at once abandoned as a place of residence.

The place was many miles from any railroad and was approached by several hours of boat journeys through lakes and the "carrys" connecting the lakes. The encampment included cottages, half-tents, boat house, guide house, and a large main club house with barns and outbuildings, numbering a score in all. These structures were loosely grouped on a hill rising from the shore of the lake and within an area of half a mile in length by a quarter of a mile in breadth. In front was the lake, while the back and sides of the clearing were

*Read at a meeting of the Section on Medicine at the New York Academy of Medicine, February 21, 1911.

bounded by mountain woodland. Besides the camp there were two or three isolated cottages on this small lake. A village of four hundred inhabitants was located more than two miles away upon a lake adjoining, where there were also some separate cottages.



During the winter and spring the large camp is deserted, with the exception of a caretaker and his family. In June and July the members of the summer colony arrive and the camp becomes fully populated. In August last there were between eighty and ninety persons living in the colony. For the most part these were families of city people, their guests, and house servants. In addition were the caretakers, boatmen, guides, and caddies for the golf links.

There was no sickness during the months of June or July. On August 13 one golf caddy went to bed with a fever and other symptoms which the local physician thought resembled typhoid. August 14 another caddy came down with the same symptoms. The same day a laundress went to bed with a fever. August 16 six more caddies were taken sick, and August 20, three more. Thus, during the period from August 13 to 20 there were eleven caddies and one laundress attaeked with an infection which Widal tests and blood cultures later on demonstrated to be typhoid fever. All of the caddies boarded in a large house located at the north end of the camp, known as the Guide House. In this lived the chief guide and his wife and twelve-year-old son, and a hired girl. Besides the caddies there were seven other boarders, namely, three laundresses, three laborers, and the golf professional. This house was an institution in the matter of food supplies and eating, entirely independent of the rest of the colony.

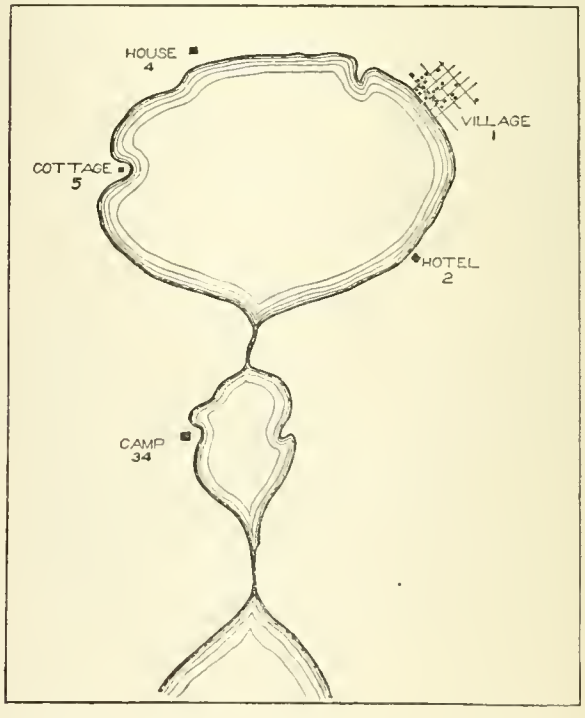
All of the cottages and tents which composed the main body of the camp were tributary to the large club house in the center. The club house was the general meeting place of the summer colony. All of its members and their servants ate their meals at this central place.

The caddies had all been brought to the camp from New York City, the first day in July, so that they had been on the premises continually for six weeks when attacked by typhoid. The laundress who was taken sick and who also boarded at the Guide House had been in the camp for an even longer period. Consequently the cases were evidently not imported, but were infected while living in the colony.

In handling an outbreak of this kind immediate steps must be taken to prevent secondary cases. All of the sick caddies were sent to New York City and placed in hospitals. The laundress was sent to her home in a distant village. The family at the Guide House was moved to the nearby village and other boarders were sent elsewhere. The Guide House itself was closed up. I directed the disinfection of all buildings and apartments which had been occupied by the infected persons. Bedding, toilets, clothing, and sewerage systems were thoroughly fumigated and saturated with disinfectants. A list was made of all persons exposed to the primary cases and these were assigned to duties that would prevent them from having any contact with the food or drink supplies of the colony.

The suppression of further primary cases could not be complete until the primary cause of the outbreak was discovered, but the placing of all of the more common means of transmission on a strictly sanitary footing was obviously important. An effort was at once made, therefore, to guarantee the character of all food and drink supplies of the colony and the proper disposal of its wastes. Inspection showed that conditions already existing could scarcely be improved and that in the list of more common means of transmission there was none which could be pointed to as obviously unsanitary.

A distinct line of cleavage appeared between the



supplies and wastes of the main colony and the supplies and wastes of the Guide House in which the typhoid cases had occurred. The explosive character of the outbreak caused the milk supply to come first under suspicion.

Milk Supply.—The milk of the main colony was

secured from five cows pastured on the premises. These were milked in the open air in the pasture excepting in rainy weather, when they were milked under an open shed. The milker wore a white duck uniform and cap and white cotton gloves on his hands during the milking. The gloves were sterilized by boiling every day. The milking pails were covered and had small openings protected with sterile cheesecloth. All dairy utensils were washed and sterilized with boiling water in the large kitchen of the club house. The milk was cooled in the club house refrigerator room.

The milk of the guide house, on the other hand, came from one cow, the property of the chief guide, pastured in the same field with the others. The guide himself or his twelve-year-old son always did the milking and personally carried the milk to the guide house, where it was cared for by the housekeeper or the hired girl, who also had charge of the milk pails and pans. Close questioning failed to discover any occasions when utensils or milk of the guide house were connected in any way with the supply of the club house.

Foods.—The club house secured all groceries, meats, fruits, butter, and eggs from New York City. Its fresh vegetables were produced in the garden on the premises. The guide house, on the other hand, purchased all supplies from the nearby village. It had no garden and used no fresh vegetables or fresh fruits during the entire season, depending entirely upon canned goods to the great complaint of its boarders.

Water Supply.—The water supply of the entire colony, including the guide house, came from a spring three-quarters of a mile above the camp on the side of an uninhabited mountain. The water was caught in a reservoir of masonry, properly covered and screened and piped to all parts of the camp in iron pipes. This water was of the purest kind, showing an average of only five bacteria per cubic centimeter by bacteriological examination, and giving no fermentation test.

Fish and Shellfish.—For the main colony there was a regular supply of fish and shellfish from New York City. The guide house used no fish whatever.

Ice.—A large ice-house was located on the hill above the cottages in which was stored ice cut from the lake. Two samples of lake water taken at the shore-front in August showed the presence of 104 and 156 bacteria per cubic centimeter, and no evidence of *B. coli*. The lake water was, therefore, pure, and the process of freezing and storage for a number of months would make such ice practically sterile and certainly destroy all typhoid bacilli.

Sewerage System.—There were no outdoor privies. All buildings, including cottages, half-tents and guide house, were equipped with most modern plumbing, toilets, bath-tubs, sinks, etc. The drainage was collected by underground tile pipes and led into cesspools. Of these cesspools there were four. One at the northern extremity of the camp received drainage from the guide house and laundry. Its condition was above criticism. Two central cesspools received the drainage of the main camp, one of which showed slight evidence of surface seepage by a darkening of the soil, but there was no overflow. At the extreme south end of the camp was a cesspool into which flowed drainage from several cottages and tents. This pool was full and overflowing.

Garbage.—The garbage in the main camp was deposited in water-tight iron receptacles. This and other waste was collected daily by wagons and carried to an incinerator three-quarters of a mile away in the woods, where it was at once entirely burned. Garbage from the guide house was not so regularly collected, and some of it was at times thrown out on the nearby hillside.

Insects.—All of the buildings in the camp, including the guide house, were well screened with fine wire screens against insects. The main club house had screened doors as well as screened windows, but in the guide house there were no screens upon the doors.

Summarizing these conditions one could find no obvious fault with the milk, or with water, foods, plumbing, screening, or disposal of waste of the main camp. The defects mentioned in the sewerage system afforded the only grounds for criticism. The thorough disinfection of the entire system carried out under the writer's direction gave at least temporary insurance against chance of infection from that source. The supplies and wastes of the guide house and its sanitary condition had little relation to the main camp, because of its almost entire independence. Furthermore, all supplies and wastes of the guide house ceased because this house was immediately closed. Consequently there was no obvious channel by which conditions which might have carried infection to the guide house could transmit disease to the main camp.

Typhoid History.—The first step in searching for the primary cause of the outbreak was a study of the typhoid history of the camp and surrounding country. In the village of 400 inhabitants, more than two miles away, there were no cases of typhoid fever during 1910. The local physicians and health officer reported that all other camps in the immediate neighborhood were free from typhoid during the present season. Information secured from several sources revealed the following list of cases:

1904—Two cases at a large hotel two miles away. The hotel has been abandoned for several years past.

1906—A maid at the main club house was taken sick within two weeks of her arrival. The local physician thought this was an imported case.

1906—A sister of the housekeeper while boarding at the guide house was taken sick after several weeks' stay.

1907—A carpenter while boarding at the guide house.

1907—Two persons living in a house on an adjoining lake.

1908—Two housemaids and a small girl at a cottage one mile above the main camp.

1908—A farm hand while boarding at the guide house.

1909—Two boys at a cottage one mile above the main camp.

1909—A laborer in the village.

A laundress while boarding at the guide house.

A laborer while boarding at the guide house.

Two carpenters while boarding at the guide house.

One golf caddy while boarding at the guide house.

One golf caddy sick with fever while boarding at the guide house, suspected typhoid, but no definite diagnosis.

1910—Eleven caddies, and one laundress while boarding at the guide house.

If we summarize all of these cases it appears that in the main camp itself there has been only one case, and that was probably imported. At the guide house there had been during four years previous to 1910 8 positive cases and one suspected case, while in 1910 there were 12 cases. At a cottage one mile away during two previous years there had been 5 cases; in the village during five years there was only 1 case, while at the large hotel there had been two cases and at the house on the adjoining lake there had been 2 cases.

For the region during five years there had been 31 positive cases and one suspected case, and of these 20 positive cases and one suspected case had been boarders at the guide house. The guide house itself had acquired a reputation as the home of typhoid fever. The popular belief was that its walls and floors carried the disease from year to year.

The primary cause of typhoid infection must always be the excretion of a previous case of the disease of either the acute or chronic type. Such cases may be located in the immediate neighborhood where a typhoid outbreak occurs, in which event the transmission of the disease may be through immediate infection of foods or drinks, on the premises, or by contact. On the other hand, the case or cases of typhoid responsible for primary infection may be geographically remote and the disease conveyed over long distances by means of food or drink. These two possibilities had to be considered.

Against remote sources of infection as the cause of the outbreak were these facts. Milk and water supplies were local. All foods for the guide house came from stores in the nearby village, which stores were patronized also by the 400 inhabitants of the village, among whom there were no cases of typhoid fever. The daily menu of the guide house shows only canned vegetables, dried fruits, meats, cereals, and eggs, all of which were cooked foods.

The strict localization of the outbreak in August to the guide house was a strong argument in favor of a local source of infection. Cooked as well as uncooked foods would be exposed to such an infection. The source would have to be either an acute or chronic case of typhoid on the premises. There had been no acute cases since the previous year. Any infectious matter discharged the summer before would have perished through the operation of natural causes in a few weeks or a few months at most. The logic of the situation suggested a chronic case of typhoid fever on the premises and the obvious place to look for such a "carrier" was the guide house itself. The eight cases which had occurred there during the four preceding years made it proper to look for some person who had resided there during that entire period, as well as during the present summer. Tabulation of the inhabitants showed that only the chief guide, his wife and son fulfilled this requirement.

In studying the probability of the housekeeper herself being a typhoid carrier, the following facts were secured: The eleven caddies all sat at one table in the dining-room. No other person sat at this table. These boys were waited upon only by the housekeeper herself; she did not wait on any other table. She admitted having had typhoid fever herself twenty years ago. Her husband and son had never had the disease to their knowledge. She had been employed at a large hotel during the summer five years before, when two cases of typhoid fever occurred there. Her duties were connected with the dairy and milk supply of the hotel. In the summer of 1909, as an accommodation, she had cooked a meal at the cottage one mile away from the main camp, and two weeks later two boys in the family living there were taken with typhoid fever, as before mentioned.

It is interesting to record that three boys from the nearby village also acted as caddies on the golf links and joined the others in all of their duties and sports. They led a life in common in every way, with the single exception of their meals. The village boys all brought their lunch with them and returned home for dinner in the evening. Not one of these three village boys was taken ill.

The circumstantial evidence connected this woman with the food supply of four out of the ten cases which had occurred outside of the colony during the past five years and with the food supply of all of the twenty cases occurring in the guide house during that time. It seems particularly noteworthy that her services in the dining-room were strictly confined to the table at which sat all of the eleven caddies who were stricken with the disease.

Laboratory examination made of her blood and bowel discharges and urine and of similar samples from her husband and son gave no evidence of the existence of a chronic infection. Only one sample, however, was obtained in each instance, and consequently the results could not be regarded as final. The housekeeper was therefore considered a most probable cause of all of the cases occurring at the colony.

Her removal to the village and the fact that the outbreak had been strictly confined to the guide house made the writer feel warranted in reassuring the members of the colony as to the safety of the main camp as a place of residence for the remainder of the season. It being the month of August the majority of the campers planned to remain in the camp for at least a month or six weeks longer.

September Outbreak.—On September 19 five persons in the main camp were stricken with typhoid fever. From September 26 to September 30 four more were taken down. On October 2 there was another case. From October 2 to October 8 there were four more cases. That is to say, from September 19 to October 8 there were fourteen cases of typhoid among the members of the main camp, all of these persons eating at the main club house. Of these fourteen there were two deaths.

The shock of this new outbreak was felt with all the more force by the members of the colony because of the sense of security resulting from the removal of the apparent cause of the August outbreak. The shock was felt to an even greater degree by the writer because of the doubt this new outbreak cast upon the accuracy of previous observations and deductions. The only crumb of satisfaction to be gathered by him was the confidence which the members of the colony displayed by again asking him to investigate the cause of this new outbreak.

Since all cases in August were confined to the guide house while all cases in September and October were in the main camp, no theory which limited the cases to the guide house would be adequate to explain the later outbreak.

Three possibilities presented themselves: (1)

That the suggested cause of the August outbreak was correct and that later outbreaks were connected in some way with the August outbreak. (2) That the suggested cause of the August outbreak was correct and that later outbreaks were in no way connected with it, but had an entirely independent cause. (3) That the suggested cause of the August outbreak was incorrect and that an undiscovered cause existed which was sufficient to explain all of the outbreaks of this year and possibly also the cases of previous years.

In an investigation of this kind prejudice is a dangerous thing, yet the circumstances seemed to suggest a single and a still unknown cause of all outbreaks as the most probable of the three theories.

No change had occurred in the general conduct of the colony since August in the matter of food supplies and drink supplies, with the single exception of a supply of cream which was purchased for the last few weeks from a creamery fifty miles distant. All of the members of the colony used this cream in coffee, on cereals, etc. Inquiry at the source of supply showed only one case of typhoid in that part of the country, and this case was not in any way connected with the dairies producing milk. No outbreaks of typhoid fever had occurred among the many other customers to whom cream was shipped from this creamery.

A new assistant chef had arrived at the colony during the latter part of August, but as he was among those stricken with typhoid in September he was a victim rather than a cause of the outbreak.

A large picnic in the woods was attended by most of the members of the colony on September 6, but four of the cases of typhoid were among persons who did not attend this picnic.

While the cases in September and October were distributed over several weeks yet they were grouped in a manner that suggested a series of explosive outbreaks. This characteristic suggested the milk supply as being the means of transmission. A complete tabulation was made of every person who came to the camp during the summer and of the dates of their arrival and departure, and of their habits with respect to milk drinking. Information could not be secured concerning all, but the list from whom it was secured included seventy-nine persons. These were divided into three classes, as follows:

Frequent milk drinkers.....	27	Typhoid cases	13
Occasional milk drinkers ...	26	Typhoid cases	0
Drank no milk.....	26	Typhoid cases	0

Concerning one of the typhoid cases information could not be obtained. We then had a piece of information that pointed emphatically to the milk supply of the colony as the means of transmission.

Reference has already been made to the five cows in the pasture of the camp as the source of the milk supply and to the milker in white uniform and sterile cotton gloves, who had charge of the milk handling. This man was a young fellow formerly a gardener who had never had typhoid nor been exposed in any way so far as he knew, and appeared to be in perfect health. This was his first season on the premises. There was no reason to suspect him as the cause of the disease apart from his connection with the milk supply.

No reference has been made heretofore to the fact that the cottage located one mile away from the main camp, where five cases of typhoid fever had occurred during two previous summers, received its milk supply from the main camp dairy. This fact seemed in no way pertinent to the August outbreak at the guide house; but the outbreaks at the main camp in September and October and the limitation of these cases to persons who were frequent milk drinkers made this fact a very important one.

The milk for this cottage was regularly carried from the main camp by a man who in former years had been a famous guide, but now was employed as night watchman at the colony. As his last duty before retiring to his daytime sleep, he met the milker of the colony's cows at the kitchen of the club house and there assisted him in measuring out that portion of the milk which he carried to the neighboring camp. This night watchman had performed this duty every morning every summer for a period of five years.

He had discussed his duties with me in August. Among other things he mentioned that in the winter time he was accustomed to act as a professional nurse in the employ of the town authorities, particularly for cases of infectious diseases. Thus, he stated that he had nursed cases of smallpox, measles, scarlet fever, and many cases of typhoid fever.

Here, then, is a man who had had some connection with cases of typhoid as nurse and who was one of the very few persons who had lived consecutively in the colony during five summers, and who was also in regular touch with the cottage one mile away, and above all, he had access to the milk supply of the club house, and of that cottage. His connection with the guide house was not so plain yet his other connections made him a decidedly suspicious person.

In September the camp was abandoned. The members of the summer colony were scattered. The suspicions which seemed strong to the writer did not appeal with equal force to others. Consequently, it was a matter of some difficulty and delay before this guide could be brought to New York to undergo laboratory examinations which seemed to the writer most important.

These examinations were at length begun, and for the sake of thoroughness and corroborative evidence they were conducted simultaneously by three separate and independent laboratories. The patient came to one of the laboratories each morning and passed bowel discharges into a receptacle which had been previously sterilized. This he did daily for a period of nine days. The discharges each day were very copious and diarrheal in character. This diarrhea was at first assumed to be a temporary disturbance, but upon inquiry the man stated that his daily discharges were always of that character, and had been so as far back as he could remember. This man is seventy-nine years of age, and has never been seriously sick nor had typhoid fever, so far as he can recollect. He is an unusually strong and hearty specimen of manhood, and is still able to pursue his hunting and trapping in the winter season.

Out of sixteen specimens examined the typhoid bacillus was isolated in pure culture fourteen times. In most of the samples the typhoid bacillus was present in enormous numbers almost to the exclusion of any other kinds of bacteria. Conradi-Drigalsky, Hiss, Endo, and the media of Jackson and Melia were used. Of these the Conradi-Drigalsky medium gave the most numerous and typical colonies; the

Hiss medium gave typical colonies, but not in such abundance. In one sample where all direct plating methods failed the use of a preliminary culture in lactose bile was the means of securing the typhoid bacillus by plates made from the bile culture.

The laboratory examinations resulted as follows:

Sample.	Laboratory No. 1	Laboratory No. 2	Laboratory No. 3
1	0	0	0
2	Typhoid	Typhoid	0
3	Typhoid	Typhoid	Typhoid
4	0	0	0
5	Typhoid	Typhoid	Typhoid
7	Typhoid	Typhoid	Typhoid
9	Typhoid	Typhoid	Typhoid

Blood examinations were made and positive agglutinations secured in dilutions of one to fifty for thirty minutes, using a stock typhoid culture and his own species. His own species was identified by the usual cultivations in differential media and also by agglutination with typhoid immune sera from hospital cases and from immunized rabbits. This man, then, is a chronic carrier of typhoid bacteria, and has apparently been such for many years. His daily diarrheal discharges make him peculiarly liable to carry infection by his hands or clothing.

Infection of his fingers must be a common occurrence. The dipping of milk with a small measure from one can to another as performed by him each morning in the club house kitchen gave abundant opportunity for transfer of infection from fingers to milk. The milk dipped by him was carried to the cottage one mile away and without much doubt its occasional infection was the cause of the five cases occurring there during two summers.

That the main camp should have escaped infection for so many years is marvelous. The occurrence of infection in the present instance may be explained by the fact that in August a new milker was placed in charge of the club house cows. His home was in the nearby village, and he had never been connected in any way with typhoid fever so far as he knew. He was instructed in the methods of storage and milk handling by the night watchman. One of these duties was the measuring of the entire quantity of milk used at the club house on the first of each week by dipping with the quart measure. The initiation of this new man perhaps gave the night watchman more than usual opportunity to transfer finger infections to the milk.

From a general point of view the fact that this typhoid carrier had lived in the camp during the five years in which there had been typhoid cases there would make it strongly probable that he had in some way been connected with all of them. His dwelling was a barn at the extreme northern end of the camp. He was alone there and boarded himself, purchasing his supplies from the village. The guide house was distinguished from the rest of the camp by its nearness to this barn. The distance between the two was a few hundred feet, while the other buildings were much further away. Living next door to a typhoid carrier was a very suggestive reason why typhoid outbreaks had for so long been limited to the inhabitants of the guide house.

Any direct connection of sufficient significance was hard to prove. The watchman's duties required him to awaken the laborers who slept in the guide house by knocking on the door of their rooms at 4:30 A. M. each day. But he asserts that he never had occasion to invade other parts of the house nor had any contact with its food or drink supplies. There was, in fact, a coolness between him and the family in the guide house which entirely prevented social intercourse.

Close questioning of the caddies failed to discover any connection between them and this man. They at times passed the barn where he lived, but never had access to any of his food or drink supplies. Direct contact being difficult to find one naturally turns to a consideration of some indirect mode of transmission. Among these flies are prominent.

At the northern end of the camp were two conspicuous foci for the congregation of flies. First was a large manure pile in the barnyard, undoubtedly used as a hatchery and as the headquarters for flies in that part of the country. The second was the kitchen of the guide house, whose pleasant odors and abundant food supplies would do much to attract flies even from a manure pile. The distance between the two was perhaps four or five hundred feet. There is no question, therefore, that flies made frequent excursions between these places. The only other place of attraction for flies in the camp was the club house kitchen, located much further south, to get to which flies from the manure pile would have to pass directly by the guide house kitchen. While there were screens on the windows of the guide house, yet there were none on the doors. The enormous numbers of flies which inspection discovered in the club house kitchen which was equipped with screen doors indicated that the guide house kitchen, when in operation, must have been infested to an even greater degree.

The night watchman had had his sleeping quarters in the barn for five years. He admits that his bowel discharges were daily deposited on the manure pile in the barnyard.

Here, then, it seems to the writer that there are all of the elements necessary to explain the connection between this typhoid carrier and the cases occurring in the guide house, not only during the summer just passed, but all of the cases of previous summers.

The transmission of the infection by flies passing from barnyard to kitchen also explains why the cases should have been limited to the guide house, for it is not unreasonable to believe that infected flies did not travel further away from their headquarters at the barn than to the guide house kitchen.

There are numerous assumptions which are competent to explain why the infection was irregular. The discharge of infectious matter was only occasional, some flies carried infection and some did not, some foods are more attractive to flies than others, caddies may have received food or cream which others did not, etc.

Because of the strong circumstantial evidence already described against the family of the guide house connected with the typhoid cases occurring there this family was also induced to come to New York City. For a period of three weeks all of them were subjected to daily examinations, but it was not possible to find any indication of typhoid infection through their bowel discharges, urine, or in their blood. Such a negative result, of course, does not entirely remove the possibility that some member of this family may be a typhoid carrier for the reason that some carriers go for periods of several months without discharging any typhoid bacilli. Yet the writer feels that developments warrant the belief that none of these people were connected with the guide house cases, but that the night watchman

was the primary source of infection for all of the cases occurring there and in the main camp.

The proper disposition of such a typhoid carrier is not yet determined. The State Department of Health was appealed to, but the Commissioner declared he was without authority to restrict the movements of such persons, and there was no way to prevent them from being the cause of further outbreaks. The writer therefore released this man with admonitions regarding personal care as the only safeguard against further transmission of the disease. He has consented to undergo treatment, and I propose to try the effects of typhoid vaccines and of milk cultures of lactic acid bacilli in his case. The treatment must, of course, be accompanied by blood tests and bacteriological examinations of feces and the work carried on over a considerable period of time. The New York Milk Committee, which is working in the interests of pure milk for New York City and for children, will pay the expenses connected with this work.

The material contained in this report was gathered during several months and through the cooperation of a number of persons. I am under obligations to Dr. E. E. Cary and to Dr. S. V. Haas for information regarding the typhoid cases in their charge. William T. Carpenter, one of my associates, rendered me able assistance in the field work. For the examination of feces and blood and isolation of typhoid bacilli in my own laboratory, I am under obligations to Dr. Cyrus W. Field. I must also acknowledge the work of Dr. O. T. Avery and Dr. C. Z. Garside of the Hoagland Laboratories, and of Mr. D. D. Jackson and Mr. T. W. Melia, who made similar laboratory examinations of the duplicate specimens sent to them.

PRINCIPLES UNDERLYING THE SURGERY OF THE SPINAL CORD AND NERVE ROOTS;

INDICATIONS FOR OPERATIVE INTERFERENCE IN INJURIES OF THE SPINAL CORD; SURGERY OF THE SPINAL NERVE ROOTS.*

By RUSSELL S. FOWLER, M.D.,

BROOKLYN, NEW YORK.

CHIEF SURGEON, FIRST DIVISION, GERMAN HOSPITAL; SURGEON, METHODIST EPISCOPAL (SENEY) HOSPITAL.

Surgically the spinal cord is divided into the cord proper, composed of non-neurilemmatous elements beginning above at a line between the articular surfaces of the atlas and the condyles of the occipital bone corresponding to the decussation of the pyramidal tracts and ending at the twelfth dorsal vertebra; the cauda, composed of neurilemmatous elements, and the anterior and posterior nerve roots, nonneurilemmatous in the cord and neurilemmatous outside the cord.

Fundamental Principles.—The value of operative interference in injuries or diseases of the spinal cord depends primarily upon the character of the structures involved. Regeneration is possible only in those portions of the cord in which neurilemma is present; that is, in the spinal nerve roots external to the cord proper and in the cauda. Regeneration never occurs in the spinal cord proper. What does at times occur is that some of the work of a given segment may be taken up in part at least by the segment above and below the one affected through already existing anastomoses between the spinal nerves outside the spinal cord itself. These facts are the fundamental principles upon which must rest all operative interference. A knowledge of them combined with an exact knowledge of the anatomy and physiology of the nerve roots, the cauda and the cord proper with an exact knowledge of the pathology of the lesion is essential. The most important underlying principle is that where there is neurilemma regeneration occurs; where there is no neurilemma regeneration is impossible. Whatever structure is involved degeneration is certain but only in structures containing neurilemma may regeneration be expected.

Knowing these fundamental facts, we can state with a fair degree of exactitude what may be expected or accomplished in the treatment of given lesions. If the lesion, traumatic or otherwise, destroys the spinal structure itself, whatever damage has been inflicted to the cord by it is permanent, though some improvement of symptoms may be expected through already existing nerve anastomoses. There is no anatomic proof of cord regeneration. All experimental studies disprove it. The most that has been observed is the beginning growth of nerve fiber in the scar itself or in the uninjured dura, both devoid of any functional value. Our hope of better results in such cases is through already existing nerve anastomoses or through making such anastomoses. This is a field worthy of considerable study.

General Consideration in Diagnosis.—In injuries of the spine the basis of diagnosis rests upon the character of the traumatism, blows, falls on the buttocks, incised wounds, gunshot wounds, flexions, sudden or gradual (apparently slight injuries may produce contusions with either immediate or late zonal paralysis); the onset of the paralysis, whether immediate or late; the character of the paralysis, whether motor, sensory, or mixed; the extent of the paralysis, whether bilateral, unilateral, or irregular. In diseases of the spine the diagnosis rests upon the same basis except that an inquiry into antecedent disease is added. Radiography is valuable in both either by showing or excluding bone injury and bone disease. Spinal puncture is valuable in confirmation or exclusion, and also important in the treatment (relief of pressure in hemorrhage). Blood examinations are useful. Wassermann in syphilis; leucopenia in tuberculosis if there is not a mixed infection present. Coagulation time in hemorrhage into the cord in hemophilia.

Spinal Commotion—Spinal Concussion. This would seem to be analogous to cerebral commotion or concussion. There are no characteristic symptoms, and if commotion occurs it has not yet been definitely demonstrated. Such a commotion is conceivable when the force exerted stops short of actual contusion. Schmauss, quoted by Murphy, has shown that zonal edema of the ganglionic cells and axones with temporary interference with function can be produced in traumatizing the cords of rabbits.

The distinction between a partial and a total lesion may be made in most cases with a fair degree of certainty, but a partial lesion may give all the symptoms of a total lesion during the first few hours or even during the first few days. In these cases there is probably present zonal edema, as shown in Schmauss' experiments. In total traumatic lesion there is definite loss of tendon reflexes (Bastian-Bruns), but this loss cannot be taken for absolute proof unless persistent, for in many cases of partial

*Read before the Brooklyn Society for Neurology, January 26, 1911.

lesion temporary loss of tendon reflexes is observed. In some cases the reflexes have been absent for eight days (De Quervain). The presence of tendon reflexes, however, practically proves the absence of a total lesion. No distinction can be made between compression and contusion by the nature of the nerve disturbance. Nor can distinction be made from a study of the bone lesion. We may surmise but cannot be certain. Extramedullary hemorrhage and hematomyelia can be differentially diagnosed but not always with certainty.

Indications for Operation in Traumatic Lesions of the Cord.—Trauma to the spine is in no way comparable as regards indication for operative treatment to trauma to the skull. As soon as the case comes under observation a complete record must be made as regards the exact location and extent of the anesthesia and paralysis and so far as possible of all symptoms in their order from the time of injury.

Extradural hemorrhage (extradural hematoma) gives no indication for operative interference save when increasing pressure symptoms are present, when laminectomy should be done at the original level of the hematoma with removal of the clot, and, if possible, ligature of the bleeding points; or if this is impossible, providing a free exit for the effused blood. Such a procedure is rarely necessary. In case the hemorrhage is situated in the region of the medulla the indication for operative interference would be more immediate, as evidenced by increasing respiratory embarrassment. In such a case, if the respiratory interference was marked from the start, there is probably present also contusion of the medulla, which would render operative intervention unavailing. If there was a previous period of non-interference with respiration, no matter how short, followed by increasing respiratory embarrassment, the indication for intervention is plain.

Intradural hemorrhage gives no operative indication unless increasing pressure symptoms occur. If such occur they should be immediately relieved by lumbar puncture repeated as often as occasion demands. Should the primary hemorrhage be in the neighborhood of the medulla the same symptoms are noted as in extradural hematoma and the same difficulty will be experienced in differentiating the lesion from contusion of the medulla, which, of course, may be concomitant in either case. The differentiation can only be made if there is clearly established a history of primary non-interference with respiration followed, usually suddenly, by rapidly increasing respiratory embarrassment. Even so the differentiation between intra- and extradural hemorrhage at this point is almost impossible, so that in the presence of increasing respiratory embarrassment occurring not immediately following the injury but after an interval of a few minutes or longer, the only safe method of treatment would be immediate lumbar puncture, and should this not be efficient or be negative, an immediate laminectomy. If the symptoms in either extra- or intradural hemorrhage in this region are not progressive, the case should be let alone and only operated later if symptoms persist showing incomplete absorption of the hematoma.

Hematomyelia. Early operation is indicated in all cases of hematomyelia. The symptoms are due to extension and pressure of the intramedullary bleeding. The indications are plain for speedy relief of this disintegrating fluid pressure before extensive separation of ganglionic cells occurs. The later stages of the lesion closely resemble syringomyelia. If the gray matter is involved there is wasting of muscle and anesthesia with zonal absence of reflex; in the white matter, paraplegia below the level of the lesion. Recovery can never be perfect on account of the destruction of ganglion motor cells. Late operation will probably be of no avail, as the destructive lesion is soon established.

Contusion must not be confused with zonal edema, which is transitory. Such an edema is seen at times after laminectomy. Here the cells themselves are not destroyed but somewhat swollen and separated from each other by minute effusion, a minor degree of contusion without destruction. Contusion is usually associated with injury to the tissues surrounding the cord. The symptoms vary and are not characteristic. There may be no symptoms at first. In a few days or weeks there may follow gradual complete zonal paralysis. The paralysis of motion may be immediate; sensation may not be entirely lost but may be blunted. The diagnosis of contusion alone is based upon sensitiveness to pressure, either immediate or late, over the spine at the level of the contusion and nerve disturbance varying in severity and time of onset below the level of the point of tenderness without disturbance of the bony parts, as shown by examination and radiographs. In no case can the severity or the permanency of the lesion be definitely established by the degree of paralysis. Having excluded fracture-dislocation operation is contraindicated except lumbar puncture in complicating intradural hemorrhage.

Fracture of the Arch. Early operation is indicated if the nerve disturbance can be attributed to the fracture. An exact examination of the spine is essential and radiography will furnish valuable aid in arriving at a conclusion. Later operation is indicated if there has been no early operative interference and if the nerve disturbance has not improved spontaneously, or if aggravation of symptoms occurs (due in some cases to callus formation).

Fracture-Dislocation. Early intervention may be useful, though not presenting much chance of success if bloodless reduction has failed, in cases in which the symptoms are those of a partial lesion. The results will be favorable in compression between the body and the arch, but negative in contusion. If early operation is not done, a later operation should be performed if spontaneous improvement has not occurred or if aggravation of symptoms occurs. The addition of callus formation to the compression of the fracture-dislocation may be the cause of the aggravation.

Incised Wounds. Operation is contraindicated.

Gunshot Injuries. Early operation is indicated if a radiographic examination discloses the presence of the bullet in the vertebral canal. Early intervention may be useful even if the bullet is not in the vertebral canal, for the compression may be caused by a bone splinter. Radiography will disclose the condition of the bone though a small splinter may escape recognition. In contusion or partial section operation will not help. Late operation should be done if early operation has not been performed in those cases which have not improved spontaneously or in which an aggravation of the symptoms occur, as in later callus formation.

Injury to the Cauda. The treatment of injuries to the cauda differs radically from that of injuries to the cord proper. Here the nerve fibers are neurilemma covered and are therefore capable of regeneration. In injuries (fracture, stab, or bullet wound) occurring in or below the twelfth dorsal.

in which the cauda has supposedly been divided, exposure and suture is positively indicated (Murphy).

Total Lesions. Formerly early operation was done in most of these cases. Now, however, early operation would only be indicated in the cases and for the reasons previously indicated.

Results. DeQuervain's analysis of 218 cases, both mild and severe, shows the following: Cured, 13.8 per cent., of which 10.5 per cent. were favorably influenced by surgical intervention; improved, 22 per cent., of which 16 per cent. were improved by surgical intervention; remaining without change, 37.2 per cent.; unfavorably influenced, 1.8 per cent.; died soon after operation, 25.2 per cent.

Surgery of the Nerve Roots.—Historical. Bennett, on December 24, 1888, following a plan outlined to his colleagues December 11, performed laminectomy, and divided, intradurally, hurriedly on account of the collapse of the patient, what were taken to be the lower four lumbar and two upper sacral posterior nerve roots, for the purpose of relieving a painful spasmodic condition of the left lower extremity. It was his purpose to leave the fourth and fifth sacral roots intact in the hope that the control of the bladder and rectum might not be interfered with. The patient died some ten days after the operation, but the detailed report shows marked improvement in the painful condition. Abbe, on December 31, 1888, following the suggestion of Dana,* made September 25, 1888, performed hemilaminectomy sectioning, extradurally, the sensory and motor roots of the sixth and seventh cervical nerves for a painful spasmodic condition of the upper extremity. The operation had no effect upon the patient's pain. Forty-eight hours later the dura was opened and the posterior roots of the seventh and eighth cervical were resected intradurally. The patient was under observation for between seven and eight years after operation. A consideration of all the facts in this case indicated a marked improvement. It is evident from a comparison of these dates that the idea of sectioning the posterior roots for the purpose of relieving pain, occurred independently to both Dana and Bennett, the first sectioning operation being performed by Bennett, the first resection by Abbe.

Abbe has reported several cases since his first. McCosh operated in one case; Horsley in two cases. Keen, in 1895, suggested that in addition the root ganglion be broken up. These were the early workers in the field. Murphy, in a masterly contribution entitled "Neurological Surgery," in April, 1907, suggested, in cases of infantile paralysis, exposing the cauda, identifying the fibers leading to the paralyzed muscles (as was done in his case of resection of the spinal cord with end-to-end suture), and approximating them to neighboring fibers, or even transferring them to roots at the opposite side of the cord. Förster, in 1908, described a new operative method (in the treatment of spastic paralysis) by resection of the posterior nerve roots. In his most recent article, 1910, he reports the results in sixteen cases out of a larger series treated by resection. In every case the spastic contractures were mitigated or entirely cured. He states that adjuvant measures are indispensable in securing the best results. As this is probably the most important contribution in this field, I have taken the liberty to quote very freely from it.

Theoretical Considerations.—Spastic paralysis is made up of two component parts; one, the paretic component, arises from the interruption of the innervating fibers of the corticospinal tract and manifests itself in a diminution in the voluntary irritability of the muscle. The second, or spastic component, consists in an increase of the reflex irritability of the muscle, *i.e.* the muscles are thrown into marked abnormal spasm by peripheral irritation carried through the subcortical reflexes. This happens because the inhibitory fibers of the corticospinal tract are interrupted. The stimuli which normally pass through these tracts to the subcortical center are diminished. The pathological increase in the reflex irritability of the muscles manifests itself: First, in an increase of the tendon and periosteal reflexes; second, in the increase in the spastic paralysis of the so-called protective leg reflex to such a degree that a simple irritation acting on one leg brings about extensive and fixed flexion of both legs. Frequently very annoying cramplike flexions occur, apparently arising spontaneously. These have their origin always in some sensory irritation. Third, the increased reflex irritability of the muscle is shown by spastic muscle contractures, which fix the limb in their position and prevent any movement in the opposite direction. Fourth, other constant associated movements are brought about which adapt themselves to the movement of the affected member so that, for instance, one leg may not be moved without the associated movement of the other, or the foot cannot be flexed without flexion of the rest of the joints of the extremity, or with each flexion of the elbow abduction of the arm and pronation of the hand follows, and finally any voluntary movement of the leg will bring about accompanying movements of the forearm, the trunk, and the head. In other words, the control of isolated movements of that extremity or portions of that extremity is lost. Even in severe spastic paralysis all innervating fibers of the member are not interfered with, and therefore, in certain portions, voluntary control of muscle is to a certain degree preserved. In these cases, in spite of a certain degree of voluntary control, the member is badly damaged because of the coexisting spastic symptoms, especially the spastic contractures and the numerous associated movements such as just described, of the elbow, wrist, and shoulder.

With all this in mind, the interruption of the corticospinal tracts, the spastic symptoms brought about by the gray matter of the cord receiving sensory stimuli not held in control by the inhibitory fibers, and so delivering these uncontrolled stimuli to the muscles, and knowing that in lesions of the corticospinal tract spastic symptoms are lacking if at the same time the root entrance zones to the posterior columns are destroyed, it follows that resection of the lumbosacral roots in severe spastic paralysis of the leg should relieve the spastic symptoms. In order not to bring about by the resection of all the roots in question (the first to fifth lumbar and first and second sacral) a total anesthesia of the leg, Förster advised a choice among the roots in such a manner that from two neighboring roots one be chosen, and in any event, not to resect more than two neighboring ones for spastic

*Extract from Dana's letter: "An exploratory operation was advised with the idea, if no tumor was found, of cutting the posterior roots of the nerves transmitting the pain. If it were a tumor, that could be removed. If it were an ascending neuritis, cutting or resecting the nerve might stop it; while cutting the posterior roots would cause an ascending degeneration and destroy the sensory tract, even into the spinal cord."

paralysis of the lower extremity, it sufficing to resect the second, third, and fifth lumbar, and second sacral root. By using this method, the spastic symptoms were markedly decreased, and in some cases entirely done away with, an encouraging amount of voluntary movements of the member appeared, and no marked sensory disturbances or no permanent ataxia was produced. It is not advisable to deviate from this method, but in certain cases an especial choice has to be made. Förster advises, in severe contracture of the knee, to resect the second, third, and fifth lumbar, and first sacral. To cure marked contracture of the knee flexors, which are produced by L_5, S_1, and S_2, resection of L_5 and the small S_2 will not suffice, but L_5 and large S_1 must be resected. In cases that have existed for a long time, and where the contracture is very firm, Förster has resected L_1, L_2, L_3, L_5, S_1, and S_2, leaving only L_4. The possibility of sensory disturbances must be taken into account. In cases of long standing rigid extension contracture of the knee from an analagous standpoint, L_2, L_4, S_1, and S_2, or even L_1, L_3, L_4, S_1, and S_2 are to be resected. In spastic paralysis of the upper extremity in which cervical 4 to 8 and dorsal 1 are involved, Förster considers resection of the fourth and fifth roots necessary. He advises sectioning C_2, C_5, C_7, C_8, and D_1 to insure permanent absence of the spasm. The sixth cervical is sufficient for supplying the necessary sensation of the thumb, middle, and index finger.

Indications for the Operation.—From the theoretical indications it is evident at once that only cases of genuine spastic paralysis are suitable for the operation. Förster deems it only justifiable in severe cases, in general, those who are bedridden. He advises operation on patients who are incapable of moderate voluntary locomotion. In cases where the presence of continued involuntary cramplike flexion movements defying every known therapeutic measure, in which the patient is in despair from the continually recurring spastic contractions, it is justifiable to perform the operation. Whether the lesion is a congenital bilateral defect of the central convolution (Little's disease) or compression of the spinal cord by a healed spondylitis or due to syphilitic spastic paralysis or a spinal spastic paraplegia of the limb in multiple sclerosis or to a hemiplegia from softening at the inner capsule or to a stab wound of the cord, *i.e.* whether cortical or cerebral, is immaterial. The site at which the cortical spinal tract is interrupted is unimportant, but the nature of the disease is of importance in deciding to operate. Congenital defects or long healed processes, as, for example, Little's disease or cerebral infantile paralysis, give a different prognosis as compared with progressive processes (softening, tumor, inflammation) which continually involve fresh centers in the central convolution and cause increasing paralysis. Operation is indicated in Pott's disease in which the tuberculous process has healed and in which the spinal cord rides upon the gibbus, but if an active tuberculous process is present operation is contraindicated. In spastic paraplegia with multiple sclerosis the rapid progression of the sclerotic process and the other symptoms of the disease must be considered. A somewhat similar state of affairs is present in syphilitic spinal paralysis which is usually held in check by specific treatment, but which sometimes in spite of this shows fresh manifestations. If the hemiplegia arises from an area of softening as a result of luetic endarteritis in a young man then resection of the roots would be more justifiable than in the case of an old man with arteriosclerosis in whom the paralysis depends upon hemorrhage into the internal capsule which may recur at any minute. The resistance of the individual and the general character of the disease must also be considered.

It must also be borne in mind that the purpose of the operation is to relieve the spastic symptoms and thereby increase voluntary movement. In order to achieve the latter it is necessary that a certain number of innervating tracts for the paralyzed member be preserved. This seems to be so in most cases of spastic paralysis. In those cases which show no movement before the operation it is not certain that after relief of the spastic symptoms active movements will return. If no innervating fibers are present or left voluntary movements will not occur. Förster considers the most favorable cases congenital cortical paraplegia of the legs (Little's disease), as here there is usually a goodly number of innervating fibers. Such cases are disabled on account of the marked spastic symptoms. There is a difference in this particular between the leg and arm. In spastic paralysis of the arm the paralytic component plays a more important rôle than in the leg. Here in general the innervating fibers serve certain important muscles which are entirely destroyed so that the final result is lessened. On the other hand, in certain spastic arm paralyses, especially cerebral infantile paralysis, in which the spastic element is most prominent, the innervating fibers for the muscle are all preserved. In such cases root resection is very useful.

Technique of the Operation. Förster's Operation.—The operation consists of a laminectomy with an opening of the dura, the identification of the roots involved and their resection. The original operation was in two stages because of its severity and because the search for the roots demands a bloodless field. Tietze, who first performed the operation, did it in two stages. Gottstein advised operating in one stage on account of the danger of meningeal infection. He endeavors to avoid hemorrhage by blunt dissection in separating the muscles from the spinal column and by using adrenalin on the bleeding bone. Anschütz used the same technique. Küttner operated nine times in two stages, once in one stage. All his cases recovered from the operation. In only one case were there symptoms of meningeal infection. This occurred a few days after operation and rapidly subsided. Kotzenberg operated on his case in two stages. Hevesi wished to operate in one stage, but was compelled to stop the operation after resecting the roots and before suturing the dura on account of collapse and could only close the dura and soft parts several days later. In spite of this the child recovered. Förster believes that the decision to operate in one or two stages can only be made in the individual case and frequently only at the operation. He noted that opening of the dura and resection of the roots influences the pulse markedly. It becomes very small and rapid. This is contrary to Abbe's experience. Collapse is especially to be looked for if the previous laminectomy has lasted a long while and the loss of blood been great. Förster calls attention to several important technical details. There should be wide exposure of the parts. For example, in spastic paralysis of the leg the arches of the first to the fifth lumbar and part of the sacral vertebræ should be removed to the facets of the transverse

processes. In spastic paralysis of the arm the third to seventh cervical and first dorsal arches should be removed. The dura should be opened very carefully to avoid injury to the nerve roots. To differentiate at the cauda equina which roots to resect the following method is useful: The first sacral root emerges from the dura just at the head of the spinous process of the fifth lumbar vertebra; this point therefore is marked by a string placed squarely across the wound before cutting off the spinous process. The second sacral root is decidedly smaller than the first. Exact anatomical studies on the cadaver are advisable. To distinguish the sensory root from the motor root Förster advises that the nerve be lifted by a small hook and without twisting to stretch it somewhat along its entire axis. This flattens it out and it will be seen that at some point there is a distinct slit between the small median motor and the large lateral sensory root. Once learned it is easy to differentiate the roots. Occasional anomalies occur; two roots may emerge from the dura through one point of exit. A long piece of the posterior root should be resected. The dura should be carefully closed by a continuous suture to prevent leakage. The muscles, fascia, and skin should be sutured separately.

Clark and Taylor working independently of Förster, but following practically the same reasoning, made their first published report in 1910. They had been working upon the subject for about three years. The reader is referred to the accompanying bibliography for a list of other writers in this field.

Sectioning the Posterior Nerve Roots in Tabetic Pains.—Mingazzine in 1899 advised intradural resection of the posterior sacrolumbar roots for relief of the lancinating pains of tabes. As an intermediate step in the development of the relief of tabetic gastric crises it is interesting to note that Vallas and Cotte demonstrated a patient at Lyons in 1906 in whom the solar plexus had been stretched resulting in an immediate diminution of the crises. Förster and Küttner in 1909 reported a case of gastric crises in which resection of the seventh to the tenth posterior dorsal roots was done. The reasoning which led to the performance of the operation is as follows: Gastric crises should be considered periodically returning irritation manifestations in relation with the sensibility, motility, and secretion of the stomach in which the primary factor is an increased irritability of the stomach mucous membrane. There is present with the symptoms relating to the stomach, pain, vomiting, etc., long continued periodic hyperesthesia of that portion of the skin supplied by the seventh to ninth dorsal roots and also an increase in the epigastric skin reflex. If the sympathetic fibers supplying the mucous membrane of the stomach according to Head are in communication with the seventh to ninth sensory spinal cord roots, and if the hyperesthetic skin zone as well as the increased reflex may be ascribed to the same nerve fibers, then the stomach crises must be considered a pathological irritation of the seventh to ninth posterior nerve roots containing sympathetic fibers. The resection of the six roots must therefore destroy at once the whole symptom picture of the gastric crisis.

Küttner was the first to perform the operation for this condition. The patient had immobility of the pupil, frequent lancinating pains in the lower limbs, bladder disturbance, parasthesia, and persistent attacks of gastric crises. Küttner performed a laminectomy first and a resection twelve days later because the condition of the patient would not permit an operation in one stage. Because abdominal colic was present he resected, upon Förster's advice, the tenth root in addition. The result was remarkable. The vomiting disappeared, the patient took nourishment, and gained at the end of four months four pounds a week. Morphine was slowly withdrawn. By the operation the preexisting hyperesthesia of the whole lower part of the thorax and entire abdomen was substituted by a girdle anesthesia which began three fingers' breadth below the ensiform cartilage and ended one finger breadth above the umbilicus. One finger breadth above and below this zone pain and temperature sense were lost, but tactile sense was retained. The hyperesthesia below the umbilicus continued, also the colic. Förster and Küttner advise from the findings in this case that in the more severe forms of gastric crises, uninfluenced by other treatment, such an operation is indicated owing its justification to the severity of the disease.

A second case reported by Bruns and Sauerbruch varies in many ways from the case just cited. There was no hyperesthesia during the crises. Between the attacks there was an area in which the tactile, sticking, and cold sense were lost and cold was interpreted as severe pain. This area extended from three fingers' breadth above the mammary line to the spines of the ileum, posteriorly from the scapular spine to the crest of the ileum. After the operation there was an anesthetic zone corresponding to Küttner's case, but tactile sense was lost above and below this zone. The operation was done in one stage. The tenth dorsal root was not resected in spite of the fact that fecal vomiting had occurred. Fifteen weeks after the operation after partaking freely of sour milk there was a slight irritation of the skin with pain followed by vomiting which was not interpreted by the authors as a gastric crisis.

Conclusion.—The future of this field of surgery is a bright one. The advances made, while slow, have been steady. The basic principles of surgery of the spinal nervous system are firmly fixed and it can at most be but a few years before the combined ingenuity of the neurologist and the surgeon will result in the practical application of these principles to the alleviation of many diseases.

THE ROENTGEN RAYS AS A MEANS OF DIAGNOSIS OF CARCINOMA OF THE STOMACH AND BOWEL.*

By G. E. PFAHLER, M.D.,

PHILADELPHIA, PA.

CLINICAL PROFESSOR OF ROENTGENOLOGY IN THE MEDICO-CHIRURGICAL COLLEGE.

The positive evidence of carcinoma of the stomach heretofore has been obtained too late in the stage of the disease to make it of much value. The disease is so frequent and usually so insidious in its onset that one should become suspicious in any case in which stomach symptoms, even though slight, develop after forty years of age, or in which symptoms develop after a previous history of ulcer. An early diagnosis is the only hope of radical relief.

Based upon a rather large experience in the Roentgen diagnosis of carcinoma of the stomach, it is my opinion that we have in this method the most positive means yet devised for the recognition of carcinoma in any stage of the disease. It stands next to an exploratory operation. Most patients postpone exploratory operation until it is too late. We cannot say truthfully that such an operation is without danger, while the Roentgen method *in the hands of an expert is accurate, painless, and harmless.* We should not wait for this method of investigation until a tumor is palpable, until cachexia develops, and until the vomitus is characteristic. At this stage the diagnosis is of less importance. Even in this late stage, the examination is valuable to determine the exact extent of the disease, so that we may know whether surgical interference is advisable. On the other hand, when loss of appetite (without any change in habits), distaste for meats, inability to digest solid foods, pain in the region of the stomach, or tenderness in the region of the umbilicus develops in a patient past forty years of age, we should at once become suspicious, and the examinations for carcinoma of the stomach should be made at once. I believe that this examination, like other special examinations, is of little value unless made by an expert.

Rieder (*Münchener medizinische Wochenschrift,* 1904, No. 35) was the first to render the alimentary tract visible by means of large doses of bismuth. Since then both he and many other Roentgenologists, prominent among whom are Holzknecht, Hulst, Levin and Barret, Groedel, Beclere, Haenisch, etc., have added to his original technique and observations.

Holzknecht and Jonas ("Die radiologische Diagnostik der intraund extraventrikulaeren Tumoren und ihre spezielle Verwertung zur Fruehdiagnose des Magencarçinoms," Moriz Perles, Wien, 1908) were the first to establish beyond a doubt this method as a valuable means of the early diagnosis of carcinoma of the stomach. *The value of this method of diagnosis depends upon the fact that carcinoma modifies the outline, position, or lumen of the alimentary canal, or interferes with the peristaltic waves, the motility of any part, or obstructs the passage of food. The earliest evidence will be some interference* with the *peristaltic waves,* and even in the stage of a small ulcer it may cause a spasmodic constriction.

Technique—Preparation of the Patient.—The patient should have the bowels and stomach empty at the beginning of the examination. I customarily order the patient to take a bottle of citrate of magnesia after the evening meal, then to come to the laboratory before breakfast on the following morning. If a woman, she should wear her kimono. I then place a small square lead mark upon the tip of the ensiform cartilage, one on the umbilicus, and another at the seat of tenderness, or at the prominence of the tumor if one is palpable. One should be prepared to examine the patient in the standing or recumbent posture and anteriorly, posteriorly, or obliquely.

Changes must often be made quickly, and therefore everything should be as convenient and complete as possible.

Roentgenoscopic (Fluoroscopic) Examination.—In the diagnosis of carcinoma of the stomach and bowel probably the most valuable evidence is obtained roentgenoscopically, but the roentgenograph or plate can in no sense be ignored. Unfortunately fluoroscopic work is dangerous to the operator, and except in the hands of one who is more or less expert it is dangerous to the patient. The great improvement in apparatus enables us to use much more powerful rays, but these are powerful for harm as well as for good, and unless caution is observed we will have another crop of harmful results. The worst x-ray burn I have ever seen

*Read with the demonstration of lantern slides from forty-two cases before the Williamsburg Medical Society, New York City, November 14, 1910.

was produced during the past summer by an untrained man who had one of the very best modern instruments, and he did it in two and a half minutes. I utter this note of warning because there is a tendency to grow careless and to use insufficient protection. It is often assumed that the modern apparatus is proof against deleterious effects, when, as a matter of fact, safety lies in modern knowledge, which cannot be bought from a manufacturer. In the hands of a skillful, well informed operator I believe these examinations are absolutely without danger to the patient. To the operator there is a certain amount of exposure, even under the best protection, if he makes a thorough stomach examination. When this is often repeated it becomes a danger. It may require twenty years to see the harmful results of carelessness that in the early days we saw in five years. I cannot go into detail in this paper, but the terrible suffering of the early martyrs should make us careful.

My protection consists of a diaphragm of lead ¼ inch thick and 15 inches square. The opening is controlled by four adjustable doors, each ½ inch thick. The tube in addition is surrounded by an opaque rubber cover, or by a box of ⅛-inch lead, and ½ inch opaque rubber to assist in controlling the secondary rays. The rays after passing through the diaphragm opening go through an aluminum window in a second door. The rays then pass through the patient, through a leaded glass screen, and I stand behind an additional lead screen ¼ inch thick. I control all my apparatus in the dark and from behind the lead screen. It is admitted by all roentgenologists that I am working under safe conditions. Even with all this, the secondary radiations in the room enable me to see through the bones of my hand upon the screen back of all this protection. Personally I would not advise any one to do fluoroscopic work with less protection.

I have argued upon this point of protection because I am impressed with the great value of the fluoroscope in the diagnosis of gastrointestinal conditions. Roentgenoscopically, we are able to see the food enter the stomach, the course of which enables us to judge the outline, the position, the tone of the stomach, the effects of the peristaltic waves, respiration, abdominal contractions, and massage, all of which must be practically ignored if the plate alone must be depended upon. Both are indispensable for accurate diagnosis.

The Bismuth Mixture.—Bismuth subnitrate, which was at first used in this line of work, has been practically abandoned on account of possible toxic effects. During the past four years I have been using bismuth subcarbonate with entirely satisfactory results. Bismuth oxychloride may be safely used as a substitute. I have never seen any toxic effects as a result of the large doses of bismuth. In a few instances there has been a slight gastrointestinal disturbance, consisting of nausea, and a feeling of discomfort, but these have occurred in neurotic patients in whom the nervous excitement might as easily be the cause. The bismuth is mixed with water, milk, broths, or with oatmeal, or mush, or is given in the form of a cake. During the past four years I have been using the preparations of fermented milk, such as kefir, firmilac, koumiss, etc. I find this holds the bismuth in perfect suspension and is easily digested. I use an ounce of bismuth subcarbonate to a glass of kefir or firmilac.

The Examination for Carcinoma of the Stomach.—I always begin with a fluoroscopic examination of the chest and then the abdomen, noting anything that may appear abnormal. I then ask the patient to swallow two ounces of water containing a half ounce of bismuth subcarbonate. (Of course any lesion in the esophagus must have been previously eliminated.) This is seen to enter the upper pole of the stomach, pass along the inner border and, if it meets with no obstruction, and the stomach has its normal tone, it will be carried slowly to the lower pole. If the stomach is atonic it will drop rapidly to the lower pole. If gastric dilatation be present with hypersecretion it will fall to the lower pole through the secretion like a shower. There is always more or less gas in the upper pole of the stomach, presenting a transparent semilunar area beneath the diaphragm, and to the left of the median line. This quantity of gas is excessive in aerophagy and in case of abnormal fermentation.

The bismuth water mixture (more than the above quantity of this mixture must not be given because the water becomes absorbed, leaving hard bismuth masses in the intestines) is followed to the pylorus, and if the peristaltic waves do not carry it there it must be assisted by the hands. (This is especially dangerous and the operator must wear opaque gloves.) After this mixture the bismuth kefir (or broths) mixture is given and the stomach further distended.

Carcinoma of the Fundus.—If a carcinoma be present in the fundus it may deflect the bismuth mixture from its normal course. At times one may see it flow over irregularities. If the carcinoma be large it will cause an indentation in the lumen of the stomach when it is further filled with the bismuth kefir mixture. On the other hand, if it is small, the complete filling may obliterate all evidence. Therefore each step must be observed and guarded most closely. The examination is begun with the patient standing, since this gives the most complete observation of the entire stomach. If there is evidence of disease in the fundus, the patient should especially be examined in the recumbent position, first supine and then prone, both with moderate "and complete filling of the stomach (Koehler: Lexiken der Grenzen des normalen und der Anfaenge des pathologischen im Roentgenbilde," Lucas, Graefe & Sillem, Hamburg, 1910), lays especial stress on this point. Sometimes one can outline the tumor directly by having the patient swallow an excess of air. This can be done by having the patient take many small, rapid swallows of the bismuth kefir mixture. It can, of course, be done also by giving an effervescing mixture.

Carcinoma of the Body of the Stomach.—If a tumor be present along the lesser or greater curvature of the body of the stomach it may deflect the course of the bismuth. This deflection may be due to external causes, however, such as pressure of gas in the bowel, tumors pressing from without or adhesions which pull the wall of the stomach from its normal position. If the tumor be of considerable size it will cause an indentation into the lumen of the stomach when the full meal has been given.

Hour-glass Constrictions.—It is in the body of the stomach that we most often encounter the hour-glass constrictions. In this condition the fluoroscopic study will reveal a prolonged retention of the bismuth mixture in the upper segment of the stomach. This may last from minutes to an hour or more. Gradually a small stream may be seen to

enter the lower segment and then the characteristic hour-glass appearance can be seen. If the constriction is low and more or less complete it may require considerable time to be recognized. These hour-glass constrictions may be due to (a) Carcinoma. In this instance the constriction will be permanent, cannot be influenced by massage, nor by increasing the quantity of the food, will not relax completely after a time, and a sack-like formation is likely to form if it has existed for some time. In addition to this, there is likely to be the general appearance of carcinoma shown by irregular indentations into the lumen when the stomach is filled. (b) Gastric ulcer and its subsequent adhesions and the incident contractions may cause a similar constriction. This, too, will be permanent and the stomach is likely to be adherent, but one will not find the encroachment upon the lumen by a new growth. It will, however, be extremely difficult to differentiate between the hour-glass stomach due to carcinoma and that due to the contraction of an old ulcer. (c) Spasmodic strictures associated with small ulcers on the lesser curvature have been observed often enough by myself and others (Barclay: "Gastric Radioscopy," *Archives of the Roentgen Rays*, October, 1910; Hertz, Holland, and Orton, *Archives of the Roentgen Rays*, September, 1910), to be considered in every case of hour-glass constriction. Gastric ulcer will be more often recognized by this condition than by retention of bismuth in the ulcer. These spasmodic strictures may last for an hour or more. The upper segment is, however, more likely to be funnel-shaped, instead of presenting a sack on one side; it is not likely to be constant and may be influenced by massage. (d) An hour-glass appearance may be presented in gastric atony due to pressure of a distended bowel on the outside. This false appearance can be obliterated by massage or by completely filling the stomach. (e) Hertz reports a case of duodenal ulcer, causing an appearance of hour-glass constriction. He attributes his mistake in diagnosis to his examination being limited to the recumbent posture.

Carcinoma of the Pylorus and Pyloric End of the Stomach.—This is the most frequent location of carcinoma. This is the region of the most active peristaltic waves of the stomach. Normally one can watch the bismuth mixture being carried smoothly and regularly to the pylorus, the wave beginning at about the junction of the middle and lower third of the stomach, and increasing in depth until it nearly bisects the pyloric end, producing what has been termed the antrum. This wave is interrupted if a carcinoma be present and may begin again after it has passed the area of induration. These observations are made with the first portion of food which is given. If the pyloric end is not filled by these waves, one can crowd the mixture into the pylorus. If the pyloric sphincter is found to be perfectly smooth on both the gastric and duodenal side and completely separates the gastric from the duodenal contents, this portion, at least, is not likely to be carcinomatous. If the peristaltic wave is deep and moves smoothly to the pylorus without any interruption, there is not likely to be any carcinoma present. I believe that at least in some cases in which gastric tone is good we can make a negative diagnosis. In addition to this interference with the peristaltic waves, when carcinoma is present, the complete filling of the stomach shows corresponding indentations into the lumen. Adhesions may be present which interfere with the motility of the stomach, either in connection with respiration, abdominal contraction, massage, or change of posture.

Pyloric Obstruction.—The classical dilatation of the stomach in connection with carcinoma, I believe, is comparatively rare, unless it be secondary to a previous non-malignant construction. Carcinoma develops too rapidly and causes too much vomiting to give time for the development of gastrectasis. I believe that gastrectasis is more often due primarily to a benign constriction. If gastrectasis be present one may see no peristaltic waves and enough bismuth mixture cannot be given to fill the stomach. Therefore, in such cases one must lift the gastric contents into the pyloric end. (This combined Roentgenoscopic palpation is extremely dangerous.) In the absence of gastric atony, excessive peristaltic waves are likely to be present in pyloric obstruction. Anti-peristalsis has been observed in five cases by Holzknecht and in two by myself in connection with pyloric obstruction. These conditions can, of course, only be observed fluoroscopically. In all these conditions, and at any stage of the examination, I make a Roentgenogram for closer study of details.

Sources of Errors.—The possible errors in connection with the hour-glass contraction have been previously discussed. Pressure of the spine (especially when a plate alone is depended upon) is likely to give an appearance suggesting carcinoma at the pyloric end. This is more likely to deceive one who is inexperienced in these stomach examinations. Pressure of a tumor from without, such as retroperitoneal sarcoma, or carcinoma of the pancreas, is likely to lead to error. Examinations in different positions, together with Roentgenoscopic palpation, will aid in eliminating this error. Carcinoma of the duodenum would be diagnosticated only by strictures or obstructions, leading to retention at certain points. Normally there is a very rapid passage of the food through the duodenum, so that if it is retained at any point for an appreciable length of time it is indicative of some pathological condition. I have never examined a primary carcinoma of the duodenum and mention it here only to caution against error. Retention of the mixture in a portion of the duodenum, due to a spasmodic stricture, is not so infrequent. I have seen two instances in connection with duodenal ulcer and one case in which there was a spasmodic stricture in the distal portion of the duodenum associated with extensive carcinoma of the stomach. Spasmodic strictures of the duodenum have the same characteristics that other spasmodic strictures have, in that they are not constant, are liable to be complete for a period of time and then disappear as completely. On the other hand, organic strictures are constant, usually incomplete, and never relax completely. Of course, there is no reason why an early carcinoma cannot cause a spasmodic stricture as well as an ulcer.

Carcinoma of the Bowel.—Carcinoma of the bowel can at times be demonstrated by following the course of the bismuth from the stomach to the point of obstruction. This has been done by a number of other Roentgenologists as well as by myself; probably first by Rieder, but early cases are not likely to be diagnosed in this way.

Technique.—The better method is that demonstrated by Haenisch before the American Roentgen Ray Society, September 29 to October 1, 1910. This consists in allowing a mixture of water

1000 c.c., bolus alba 300 grams, and bismuth subcarbonate 75 grams to flow from a fountain syringe into the rectum while the patient is in the supine position and watching Roentgenoscopically the mixture flow through any constriction. An organic stricture will be constant and it cannot be altered by Roentgenoscopic palpation. In this way early carcinoma can be diagnosticated. During September I examined a case for Dr. Daland, with Dr. Haenisch, in which a moderate stricture was found at the sigmoid flexure. Operation by Dr. Warmuth confirmed our findings in every detail. This portion of the bowel was excised. Pathological examination by Dr. Wieder showed this to be an inflammatory ulcer with much thickening. He has made good recovery. This patient had suffered for five years with pain and bleeding with stools, and had seen fifteen other physicians previously without getting a diagnosis. Permanent records and more detailed study should always be made by means of plates. This fluoroscopic examination, of course, involves the same danger as any other, and the same rigid rules for protection of the operator should be observed as for examinations in the upright position.

Conclusions.—1. I believe that a positive diagnosis can be made in nearly every case in which an indurating carcinoma is present.

2. In some cases in which good peristaltic waves are present a negative diagnosis can be made.

3. A positive diagnosis depends upon some interference with the peristaltic waves, some encroachment upon the lumen of the stomach, some interference with its mobility, or some interference with the functions of the pylorus. These may occur singly or combined.

4. I believe that nothing short of an exploratory operation will give nearly as much positive and definite information, though other physical and chemical examinations should not be neglected.

5. Each interpretation should be made in the light of the history and other clinical and laboratory evidences.

6. These examinations must be made most carefully, and by a trained observer, to be reliable.

7. In the hands of an expert, I believe, these examinations involve no danger to the patient, and to the operator they are dangerous only in so far as he must expose himself during the fluoroscopic examination. Therefore, the trained eye in making quick judgments and skill in manipulating the instruments will go far in reducing the exposure.

1321 Spruce Street.

THE NAUHEIM METHODS IN THE MANAGEMENT OF CARDIAC DISEASE.

By LOUIS FAUGÈRES BISHOP, A.M., M.D.,

NEW YORK,

CLINICAL PROFESSOR OF HEART AND CIRCULATORY DISEASES FORDHAM UNIVERSITY SCHOOL OF MEDICINE, NEW YORK CITY; PHYSICIAN TO THE LINCOLN HOSPITAL.

The reputation of the Nauheim methods in managing cardiac disease has suffered recently through the criticism of some cardiologists of great eminence, and through the disappointment of practitioners who have applied the methods in name but without sufficient training (not knowledge) on their own part to apply the methods efficiently. The most often quoted is Dr. MacKenzie.

Dr. MacKenzie's judgment was drawn from well-advanced and serious heart cases that went to Nauheim with the idea that it was a specific cure, and he dwells on the long-exploded statement of former times—that one could trace specific curative effects from individual baths. He also justly criticises the attempts of physicians who, however skillful they certainly are in the art of medicine, are not what might be called technologists, and who, when they attempt to engraft on their really superior art the refinements of sphygmological measurements and cardiac topography, lay themselves open to refutation of their observations by technologists.

I can perfectly sympathize with the irritation Dr. MacKenzie felt in Nauheim at dogmatic statements by some of the local practitioners and the differences of opinion among them. I am inclined to agree in the main with many of Dr. MacKenzie's criticisms because, during two summers spent at Nauheim, I felt very much some of the same things, but I went there to study the art of managing heart disease and not for instruction in technical matters, except at the hands of one or two men who excelled in technology.

Dr. MacKenzie wrote for the Scotch and English, who are a much older nation than us and who are better equipped at home for what he calls the "Spa Treatment."

I have always maintained that a man who knew the Nauheim methods and was able and allowed to apply them to his patients could get just as good results in New York as in Nauheim, but in most cases this implies very hard work and complete control.

Dr. MacKenzie drew his conclusions from the population of what he calls "a remote manufacturing town." I have always found cadiovascular disease much modified as between the laboring classes and others.

While it is the desire of every physician to analyze everything in a scientific spirit and to get at the truth, still it is unscientific not to recognize a domain which has not yet been acquired by pure science, and is still called "art." So in spite of the failure of technical medicine to cover completely the field, we must not deprive our patients of the recommendation of that which will do them, as individuals, most good.

I can agree with Dr. MacKenzie that I saw no wonderful cures at Nauheim, but to the student of the heart why should the results of a definite, planned treatment cause wonder? Heart disease is the same wherever I have seen it though presenting infinite varieties of detail, and how much less apt was it to present anything new to MacKenzie?

What I wish to defend is the proposition that there are great advantages in Nauheim for the class of Americans that go there. I would conclude by quoting the last half of p. 287 of MacKenzie's book, which refers to Nauheim, because in his own words are found all that it is necessary to claim from the point of view of the American who has not had the benefit of MacKenzie's skill or the European habits of relaxation and rest.

"Cause of the Efficacy of the Spa Treatment.—It may be said, and truthfully, that large numbers of people flock to Nauheim and many of them derive great benefit from the treatment. I recognize this and have carefully endeavored to find out the reason for the success of the Nauheim methods. When the cases that are cured and the cause of their cure are strictly analyzed, it will be found that at Nauheim what I call the essentials of treatment are carried out in an excellent manner. Everything is

conducive to the restfulness of the patient. It is a pleasant place, sunny and well shaded, with beautiful gardens and an excellent band. People jaded with their cares and duties find here that repose which is essential to the recovery of the heart. A very large proportion of them are somewhat neurotic, and there is consequently a very susceptible mental element that can be influenced. The patient comes to Nauheim buoyed up by the reputation of the place. When he consults a doctor, he is confidently told that the treatment will do him good—at once half the cure is effected in a great proportion of cases."

So after all, the most that can be said about MacKenzie's criticism, of which so much has been made, is that he denies the specific value of the treatment while acknowledging that Nauheim is an excellent place for heart patients.

BILATERAL FIBROMYOMA OF THE BROAD LIGAMENT.

By EUGENE H. EISING, M.D.,

NEW YORK.

SURGEON SYDENHAM HOSPITAL; ASSISTANT ADJUNCT SURGEON, MT. SINAI HOSPITAL.

Intraligamentary tumors are in the vast majority of instances cystic and take their origin either from the ovary or from the parovarian body. Solid tumors occurring between the layers of the broad ligament are rare, and are usually fibromyomatous in structure. Intraligamentous fibromyomata usually take their origin from the body of the uterus

Bilateral Fibromyoma of the Broad Ligament: posterior view.

and are for that reason considered secondary intraligamentous tumors, in contradistinction to that group of rare tumors collated by Vance, in *Annals of Surgery*, Vol. 46, in which no connection with the uterine body can be found. From the literature it would seem that all such tumors are fibromyomata.

The case herewith reported is unique inasmuch as it is bilateral. The patient is a spinster of forty-five years, of domestic and sedentary habits. She has suffered no untoward symptoms referable either to the genital, urinary, or alimentary systems. She has had no pain or discomfort of any kind. Some months ago she noticed a mass in the right iliac region which has been increasing in size. There has been no loss of weight or of strength. Upon examination there was to be felt in the right iliac fossa a large hard globular mass reaching half way up to the umbilicus. The mass was fixed in position and was not tender. On the left side was a similar mass which could be felt to rise above the brim of the pelvis. Vaginal examination could not be made owing to a dense and firm hymen that could not be penetrated with the finger. The condition was considered to be one of bilateral intraligamentous ovarian cyst.

Upon opening the abdomen it was soon learned that the masses were not cystic. An attempt was made to remove the one on the right side after dividing the broad ligament, but this was found impossible owing to the intimacy between the tumor and the body of the uterus. On the left side the situation was entirely similar, the tumor and uterus were not to be separated. At this moment it became apparent that in order to remove the tumor masses it would be necessary to sacrifice the uterus. Hysterectomy was done, removing simultaneously the intraligamentous tumors. The patient made an uneventful recovery. The microscopical examination of the tumor showed it to be a fibromyoma. The dimensions of the entire mass, including the uterus, as seen in the photographs are: Laterally, 7¼ inches; vertically, 4½ inches; anteroposteriorly, 3¾ inches.

DIAGNOSTIC VALUE OF TUBERCULIN AS SHOWN BY NINETEEN AUTOPSIES.

By G. W. T. MILLS, M.D.,

CENTRAL ISLIP, NEW YORK.

SECOND ASSISTANT PHYSICIAN, CENTRAL ISLIP STATE HOSPITAL.

My work with tuberculin, as a diagnostic agent in the insane, was begun in December, 1907, and during the next few months over one hundred patients on a chronic service were tested, including a number from the tubercular ward. Since then from time to time it has been used as occasion arose until we now have records of 135 eye tests. The result with the ophthalmic test, dealing with all classes of cases, have been previously presented in two papers, first in the *State Hospitals' Bulletin*, May, 1909; second, in the *Proceedings of the American Medico-Psychological Association*, June, 1909. At the present time, however, I shall limit myself entirely to the autopsy material, which covers nineteen cases.

Case 3.—Was negative on first trial, positive on the second. Autopsy was made thirty-five days after first trial, and very extensive disease of both lungs found, with large cavities at apices, tuberculous abscess of right kidney, and tuberculosis of right ureter.

Case 8.—Was the most positive in the series. Autopsy two years and eight months later showed old and recent lesions at right apex, old lesions at left apex.

Case 19.—Was strongly positive. Autopsy thirteen days later showed advanced disease of both lungs.

Case 20.—Was positive. This case, in December, 1907, had characteristic physical signs, with several hemorrhages, but repeated sputum examinations were negative. Autopsy two years and four months later showed advanced disease of both lungs.

Case 22.—Was negative. Autopsy nine months later showed rather large scars at both apices, many adhesions, and a recent abscess at root of left lung, possibly, although not definitely, tuberculous. The cause of death in this case was from the cardiovascular system and not the respiratory. The abscess may well have been a broken down spot of bronchopneumonia.

Case 29.—Was negative. Autopsy two years later showed a healed tuberculous lesion at each apex, but nothing of an active nature.

Case 33.—Was positive. Autopsy two years and three months later showed extensive disease of both lungs.

Case 43.—Was strongly positive. Death two years and one month later from lobar pneumonia. No active tuberculous lesion, but a definite old healed spot at right apex.

Case 45.—Was positive. Autopsy one year and six months later showed extensive disease of both lungs.

Case 57.—Was very strongly positive. Autopsy one year and six months later, following death from lobar pneumonia and acute pericarditis. There were extensive adhesions, both lungs, healed tuberculous lesion at left apex, and in one mediastinal gland.

Case 68.—Was negative. Autopsy two months later, old scars at both apices.

Case 69.—Gave a very slight reaction. Autopsy three days later showed tuberculous pneumonia of entire right lower lobe.

Case 74.—Was negative. Autopsy forty-four days later, and no tuberculous lesion found in any portion of the body.

Case 81.—Was negative until the thirty-sixth hour, at which time it was positive; by the sixtieth hour the reaction had almost disappeared. Autopsy one year and six months later. Our regular pathologist was away and no special attention was given to tuberculosis. The only statement that appears in the records relative to the lungs is "strong adhesions of right lung posterior." However, in life clinical signs were present at both apices, especially the right, quite clearly explicable on the ground of old healed lesions.

Case 86.—Gave a very slight reaction at the end of sixty hours. Autopsy two months later showed some apical scars and a small, well encapsulated area containing purulent and cheesy looking material.

Case 115.—Showed slight redness at the end of the eighteenth hour, and considerable mucopurulent secretion at the end of thirty-six hours, without, however, any increase in the redness; could only be called a mild or questionable reaction. Autopsy, thirty days later, showed a very far advanced tuberculous peritonitis, with many small pus pockets.

Case 122.—Was positive. Autopsy five and one-half months later showed an extensive active process, which was the cause of death.

Case 129.—Was negative. Autopsy six days later showed old adhesions and an old, apparently healed, lesion in right lower lobe. In addition, an active acute process in right upper lobe. Cause of death was erysipelas and bronchopneumonia, the latter probably not tuberculous. At the time of the test she was running a high temperature and was very ill with diarrhea and hemorrhages from the rectum.

Case 131.—Is the most interesting and conclusive, sufficiently so to justify a more detailed report. Kate McD., a single Irish woman, between 60 and 65 years old. A history of a winter cough for some years and an attack of bronchopneumonia four years before admission, from which she apparently made a good recovery, but side and extent of involvement not known. Her general health did not suffer until the onset of the psychosis, which led to her commitment to this hospital. She was admitted in a reduced physical state with a dry cough, considerable arteriosclerosis, heart sounds roughened, faint trace of albumin in the urine, but no casts. Very suspicious lung signs were also present, including dullness and râles over upper portion of right lung. Temperature normal. A few days later the râles had disappeared, but dullness was still present. For a time she was up and about, seemed to be improving, but within two weeks began to fail, the râles reappeared, although the cough was still dry. The case was regarded by some on the staff as quite clearly tuberculous. A month and a half after admission the signs were unchanged, she was most of the time in bed, but the temperature was practically normal. The ophthalmo-tuberculin test was then used and was negative. This led to her being transferred to a hospital ward. She continued to fail, but lung signs did not advance except that breathing approached more to the bronchial over the upper portions of right upper lobe. Her cough remained dry, no sputum was ever obtained, temperature was normal, respirations 18 to 20, rarely 22 or 24. She then developed a more or less persistent diarrhea, with slight irregular temperature, only once going above 101°. She was transferred to the tuberculosis camp, the physical signs being regarded as sufficient, and the tuberculin test disregarded. Slow progressive physical failure continued, she became greatly emaciated, temperature often subnormal, as low as 96°, but still no sputum. She died on April 21, 1910, six and one-half months after admission, and five months after the tuberculin test. At autopsy the immediate cause of death was found to be bronchopneumonia, the appearance of the right upper lobe was extremely suggestive, grossly, of tuberculosis, but on section no evidence was found that it was of such nature, a consulting pathologist and our own reporting it to be an unresolved pneumonia with chronic interstitial changes. There was no tuberculosis of other organs.

Conclusions.—To sum up, there were ten cases with advanced disease. Of these, four cases can be considered together. One of them (Case 129) gave absolutely no reaction, two (Cases 69 and 115) only slight reactions, and the fourth (Case 3) negative reaction on first trial, positive on second, but this was in the same eye and is without value. They all died within a comparatively short time (three days to thirty-five days), and the results correspond with the results of others and with those of the injection method, that is, in advanced or very active cases, especially just before death, the reaction is absent or slight. The other six (Cases 8, 19, 20, 33, 45, and 112) were positive, all but one lived a considerable time beyond the test, and the disease was not in as active or advanced a stage at the time of test as in the four above described. The one exception is Case 19, in which the primary cause was Addison's disease.

The next group includes the cases with scars and evidences of former tuberculosis, nothing of an active nature being present at death. In this group there were seven cases (Cases 22, 29, 43, 57, 68, 81, and 86). Three of these (Cases 22, 29, and 68) were negative; one (Case 86) gave only a questionable reaction at the end of sixty hours, and three (Cases 43, 57, and 81) gave positive reactions. This proves conclusively that old healed lesions can give positive reactions and strongly positive ones, but at the same time shows that a negative reaction does not exclude an old lesion. The third group includes two (Cases 74 and 131) with negative autopsy findings, and both gave negative reactions.

To quote, with slight alterations, from the second paper mentioned at the beginning of this

article, "The subject may, I think, be summed up in this way. About 20 to 25 per cent. of insane patients will react to the ophthalmo-tuberculin test, in whom no demonstrable lesions can be found, but it is probable that in all of them an old focus will be found postmortem. Therefore, a positive reaction in the absence of clinical signs is of no significance, but a negative reaction, except in advanced or very active cases, to my mind, positively excludes tuberculosis." These conclusions, it seems to me, are perfectly borne out by the autopsy material which is now presented.

Only one word as to the method. I believe the ophthalmic as reliable as any other tuberculin test, more reliable than most methods, and easy of application in any class among the insane. Bad results to the eye have been reported, but with strict aseptic precautions I believe the danger to be infinitesimal, and so far I have seen no injurious effects.

PROPHYLAXIS AGAINST HOOKWORM INFECTION BY MEANS OF EFFICIENT SHOES.

By W. F. ARNOLD, M.D.,

SURGEON, UNITED STATES NAVY, RETIRED.

I DESIRE to direct attention to the fact that has been repeatedly noted that hookworm infection in Europe is principally a problem dealing with certain occupations, rather than an incubus upon the whole rural population—as appears now to be the case in our Southern States; also, to put upon record the conviction that this difference of conditions here and in Southern Continental Europe is due mainly to the greater efficiency of the footwear of the peasantry there.

The machine-made shoes of America are famous alike for their attractive appearance and for their relatively small cost; but all of the recent studies of the condition of our working-classes agree in putting the cost of shoes as one of the principal items of wage-earners' expenditures for apparel. This is obviously due to their poor wearing qualities, which are ascribable to the lightness of their construction and to various devices in the manufacture of leather tending to shorten the time of its production, to improve its working qualities, etc.

But, in addition to the deficiencies enumerated above, there remains another objection, which more nearly concerns my present purpose. It is the fact that it is virtually impossible to make shoes with sewed welts that are water-tight; and it is obvious that hookworm larvæ can readily penetrate into any crevice that will admit water; in fact, it is probable that their powers of active movement may enable them to enter into places where slight hydrostatic pressures such as affect shoes and the force of capillarity would not enable water to go. Still another good proof of the ineffectiveness of common shoes may easily be verified by testing their perviousness to sand—as is done daily in most parts of Florida Not only will the particulate grains of sea-sand be found in abundance inside most shoes, but the much more finely divided, black organic matter that pervades most of the sand in that State after it has weathered for some time, will be quite noticeable both upon the stockings and the feet. Furthermore, the question of the perviousness of sewed shoes to water, muck, etc., is virtually granted by most of the persons employed in the tanning and dyeing trades; for they almost always wear, while at work, shoes with wooden bottoms. It is true that these wooden-bottomed shoes have soles that are thicker than could be made expediently of leather, whereby their wearers get the advantage of the additional elevation while at their sloppy work. But the vamps (or "uppers") of the wooden-soled shoes are tacked into place, and they are thus made water-proof. I assume that leather of ordinary body is larvæ-proof, but it may not be.* Obviously, great advantage would be secured by those who are exposed to hookworm infection if they would adopt securer footwear.

The Southern European peasantry and many domestics and cognate laborers of both sexes use these wooden-soled shoes. They do not in the least resemble the Holland nor the German *clogs*. They are indistinguishable from ordinary shoes, especially those for women, at a glance; and the only modification in use is that they are large enough to accommodate a sort of a slipper, made usually of soft kid, to prevent excessive wear upon the stockings from the unbending wooden sole. They cost about the same as the shoes usually worn by working people, in spite of the duty now levied upon them on importation. Should they prove too noisy for use in schools by the pupils, this fault could be overcome by adding sheet-rubber soles and heels.

If it be possible to popularize the use of such shoes in this country, I do not hesitate to predict more efficient protection from hookworm infection. Every up-to-date practitioner in the South can illustrate from his own experience instances in which newcomers thither have suffered hookworm infection; and, in the absence of direct proof of infection by ingestion of hookworm larvæ, which has failed so far as tried with the hookworm of the dog (*apud* Prof. Allan J. Smith†), defective footwear must be blamed for such infection, especially in bankers, druggists, and like sedentary folks, notwithstanding their indoor occupations and town lives.

Such suggestions as the foregoing naturally raise the question of removing the infection from the soil; but this is a question that I do not, personally, dare to hope to see improved. Some time ago I pointed out (*Memphis Medical Monthly*, 1907; vol. 27, p. 140) that the deficient altruism of the negroes at the South and their night-prowling proclivities, would serve to defeat this end alone, even admitting that sanitary toilet facilities were ideal everywhere. Besides, it is not yet determined how long infection of the soil remains an active danger in localities where its disinfection of hookworm larvæ by cold is not produced.

For these reasons I urge as seriously and as strongly as possible that individual protection be accentuated, and that the attention that I think that the subject deserves be devoted to providing more efficient shoes.

*Dr. C. C. Bass has demonstrated (*Journal of The American Medical Association*, 1909) the permeability of glove-kid to hookworm larvæ upon its surface with mud. But, as I am informed by practical tanners that a preponderance of the leather now used for shoes in the United States is produced by the Schultz chromate process and that it demands superior qualities of hides, it seems unlikely that good shoe-leather is much at fault in this particular.

†Upon further discussion of this point with Prof. Smith, he expressed himself as dissatisfied with the experiments that he had made from their incompleteness. It would be very useful, indeed, to have this point settled in order that diffusion of attention may be prevented and unprofitable speculation as to the means of infection may be discouraged.

"MANCHURIAN TYPHOID" AND BRILL'S DISEASE.

THAT scientific investigations of the highest order may be carried out by medical officers at the seat of war is indicated in a paper which has just appeared in the *Zeitschrift für klinische Medizin*, Vol. 22, Nos. 3 and 4. This is contributed by the late Prof. S. S. Botkin of St. Petersburg and Prof. S. S. Simnitzki of Kasan, who at the outbreak of the Russo-Japanese War in 1904 were respectively director and bacteriologist-in-chief of the medical division of the northeastern wing of the Russian army in the field. In spite of the meager facilities for careful laboratory investigation and clinical observation that are almost inevitably associated with the turmoil of war, these observers succeeded in making an important contribution to medical science, which is all the more remarkable in view of the difficulties that surrounded the work. The significance of this contribution acquires added interest when regarded in the light of the recent discussion relative to the specific nature of Brill's disease.

Among the large number of cases of typhoid fever treated by the Russian army surgeons there were many which the latter regarded as extremely atypical, and which they were at first inclined to classify with typhus fever. Later investigation showed that this resemblance was only a superficial one, and that the disease belonged to an entirely different group. In fact, typhus, although it occasionally occurs in the Far East, is an extremely rare disease, while typhoid is very common. The extensive experience with this disease during the entire period of the Russo-Japanese War, an experience that involved 21,849 cases of typhoid fever, brought out the very remarkable fact that fully one-third of these belonged to the group of diseases simulating typhoid fever. The Widal reaction was absent in from 21 to 39 per cent. of the cases. Out of this group of many varied affections closely related to typhoid fever, there was extracted a type having distinct peculiarities, and to which the name "Manchurian typhoid" has been given. Of this type seventy cases were observed, all presenting an identical clinical picture, with features that may be sharply differentiated from those of typhoid fever. This picture is very similar to that recently delineated by Brill in his study of 221 cases in New York City.

The characteristics of "Manchurian typhoid" are its sudden onset, with a chill or with repeated chills, and sometimes with vomiting. These are followed by headache and pains in the limbs or in the entire body. Rapidly the temperature rises to 102° to 104°, acquires a continuous type, with slight daily remissions of one to two degrees, until the ninth to the fifteenth day of the disease, when the temperature drops by crisis or by lysis. The eruption appears gradually or suddenly on the third or fourth day of the disease, and is characteristic, consisting of small, roseola-like and petechial spots that spread over the entire body and become particularly abundant at the flexures of the joints. The eruption is most intense during the first few days of its appearance and generally fades early and disappears two or three days before the fall of temperature. The gastrointestinal symptoms are not particularly characteristic; the liver and spleen are swollen; diffuse bronchitis is a frequent accompaniment; the nervous symptoms vary from slight mental dullness to marked meningismus, and the blood changes are not characteristic or may present a slight leucopenia.

The possible epidemic character of this disease is indicated by the fact that in one regiment six soldiers were taken ill with it at the same time. In another regiment three soldiers belonging to the same battery came down with the disease shortly after they had returned from a Chinese village, whither they had gone for food supplies. Occasional small epidemics of this disease have also been noted by Barykin among the inmates of the prison at Harbin. It is noted that this disease is not strictly confined to the Far East, but has been observed in Botkin's clinic in St. Petersburg as reported by the latter, in *Russki Vratch*, 1907, No. 49.

Of still greater interest than the clinical manifestations of this disease are the results of the investigations made of its bacteriology. Simnitzki found that the blood serum of patients suffering from "Manchurian typhoid" had a slight agglutinating action on the organisms of the typhoid-paratyphoid group, indicating that the former disease is possibly related to this group. On further investigation Simnitzki succeeded in 1904 in isolating and cultivating an organism from the blood of these cases, pure cultures of which were agglutinated by the blood serum of the patients. This organism presents the characteristic of rapid destruction in subcultures and has the following morphology: exceeding the typhoid bacillus in length, it is thinner and more delicate, with pronounced motility maintained by four or more flagella. There are distinct cultural characteristics that need not be detailed in this place. Barykin has found that this organism stands closest to the typhoid bacillus. Later studies made in Botkin's clinic in St. Petersburg showed that whereas the blood serum of "Manchurian typhoid" agglutinates its specific organism in dilutions as high as from 1 in 1,000 to 1 in 5,000, it agglutinates the other

members of the typhoid-paratyphoid group only in dilutions of 1 in 10 to 1 in 40. These results showed a definite relationship between all these organisms. Furthermore, the Bordet-Gengou phenomenon was investigated and revealed the fact that, while the blood serum of a case of "Manchurian typhoid" contains antibodies to all of the members of this group, the reaction of fixation of complement is most marked in the case of its specific microorganism.

If this disease is identical with the type that has been so carefully studied and admirably described by Brill, it is interesting to note that the Russians have possibly gone a step further in revealing its infectious cause. Furthermore, the Japanese, Horiuchi, had an opportunity of examining two of these cases at autopsy and demonstrated the presence of hyperemia of the mucous membrane of the lower part of the small intestine, particularly of Peyer's patches, with ulceration in the neighborhood of these patches and slight enlargement of the mesenteric glands. There can be little doubt that "Manchurian typhoid" represents a distinct clinical entity belonging to the typhoid-paratyphoid group. It remains for future investigation to decide whether "Manchurian typhoid" is identical with Brill's disease.

THE HOSPITAL AS AN EDUCATOR.

Dr. William Osler recently delivered an address on a very important subject at the opening of the new building of the Nottingham, England, Medical Society. The address was published in the *British Medical Journal,* February 4. The text on which he based his delivery was organization in the profession and his remarks applied almost as much to the profession on this side of the water as to that of Great Britain. The first part of his theme dealt with the need or cooperation among members of the medical profession, that is, perhaps, more especially social cooperation, and he pointed out that physicians were notoriously difficult units to unite. Once severed from the parent college a large number of practitioners live a life of isolation, and even in a city a busy man may see surprisingly little of his colleagues. Attention was drawn to the value to the local practitioner of a medical society and library, but a warning was uttered as to the wisdom of avoiding cliques. Unfortunately members of the medical profession seem to be somewhat too prone to jealousy and it is possibly the exception rather than the rule for them to live in complete harmony in a small or even moderately large city. Osler thinks that the influence of the seniors has much to do with the existence and continuance of harmonious feeling and said that he had known a clever old schemer of a quarrelsome disposition ruin the profession of a city for a generation. On the other hand, a strong old man with a good heart and a smooth tongue may keep the peace indefinitely. The second function of a medical society lies in post-graduate instruction, which should be a sort of clearing house of clinical experience, and the speaker urged that while all should be encouraged to speak at the meetings the motto, for the junior members at least, should be brevity and lucidity.

The most essential feature of medical local organization, Osler said, was that of the general hospital, and the manner in which it may be made of value in the education of the individual members of the profession, so that they may do the greatest possible good in the community. The claim was made that the physicians and surgeons and specialists of a general hospital in a city of fair size form the most valuable single asset of the profession, and collectively and singly they should be nurtured and fostered and encouraged and used wisely and well by the practitioners at large. So far as the function of the hospital in post-graduate education was concerned, it was suggested that as a class doctors do not sufficiently appreciate the importance of continuous education in their professional life. Every man in order to keep up to date cannot break away from his practice at intervals and go to a post-graduate school, but the post-graduate school may be brought to him. And it is in this direction that a function of the first importance of a good-sized city hospital intrudes, that in such an institution the medical practitioner can do his own post-graduate work.

The probable extension of post-graduate work was referred to in the address and the following recommendation of the International Committee at the last International Medical Congress at Budapest was quoted: "In large towns and cities scientific centers are to be formed at places of instruction, in which the hospitals on the spot should be made use of, and the physicians capable of teaching should act as instructors." This plan has been followed in Germany on a fairly large scale, and, furthermore, the German Government has established in a number of the large manufacturing cities academies for practical medicine which serve as centers of this post-graduate propaganda. A hospital in a city should be so equipped that it will afford adequate facilities to the doctors of the district to continue their education. Consequently each member of the staff of such an institution should make it his business to render his own department a center of information for the medical men of that section of the country. Undoubtedly the hospital plays the most important rôle in the organization of the profession. For purposes of training it is essential and as a rule in this country it is not employed as it should be in this direction. Every large hospital in London has a medical school attached and the same may be said of the large British provincial hospitals. Conditions are different here, but still the hospitals are not used for teaching as they might be.

With regard to post-graduate work it is obvious that the system should be largely extended. Many men when they have been graduated in medicine know little of the practical work of their profession and it is also necessary that a practitioner should keep himself in touch with the latest developments of medicine and surgery. Therefore, the plea for the extension of post-graduate work throughout the country, with the city hospital as the center, is abundantly justified.

LEFT-HANDEDNESS IN BERLIN SCHOOL CHILDREN.

Although the literature of this subject is a very large one, but little light has yet been thrown on the nature of the phenomenon. A list of the theories alone which have been advanced to account for the latter should make an article of ample compass. That the phenomenon is present in apes and many lower mammals shows well its deep-seated character.

Schaefer, a Berlin school physician (*Berliner klinische Wochenschrift*, February 13), has recently studied 18,000 children of the Berlin common schools from this point of view. To control so many cases he made use of a circular addressed to the parents, who were requested to designate which hand the child used for writing, eating, playing, working, etc.; also the presence or absence of an hereditary element, whether the child slept on the left or right side or back, and whether the condition developed during the school age. It was found that over 95 per cent. of children were right-handed, the girls having a slight superiority in this respect. Less than 5 per cent. were therefore left-handed. There were but thirty-seven ambidexters in the entire number (0.21 per cent.). Reckoned by grades, the lowest showed the highest percentage, this dwindling gradually to the highest grades with slight irregularities. This incidence may be explained in various ways, none completely satisfactory. Direct or collateral ancestry of left-handed children shows that about one case in three has an hereditary element. The statistical evidence shows very plainly that right-handed children tend to sleep on the right side, and left-handed children on the left side.

Mirror writing predominates in the left-handed by a wide margin. There is no evidence, however, that the speech center is notably affected. Stuttering and stammering, etc., are not more common in the left-handed. There is no evidence that a left-handed child is in any way handicapped in regard to ability to earn his living, although it is something of a hardship for him to learn "right-handed" writing. The watchword of the day is not to antagonize left-handedness, but to develop "left culture" in the right-handed and "right culture" in the left-handed, or relative ambidexterity.

The Hygiene of the Swimming Pool.

The swimming pool is greatly gaining in favor in all cities and is, it is needless to state, a more or less necessary adjunct to civilization. It may also be said that New York is very deficient in adequate swimming facilities. In London these are to be found in every part of the metropolis, some free, some at a small charge, and others of a more luxurious nature. They are all patronized very extensively and must obviously tend in the direction of health, cleanliness, and amusement. In the case of the young of the poorer class swimming baths are a boon—almost a necessity—but it is obvious that there must be considerable difficulty in keeping the water fairly clean and disinfected. Various measures to this end have been suggested, however. In the *American Journal of Hygiene* for October John W. M. Bunker discusses the matter and describes the methods taken to disinfect the swimming pool at Brown University. There is, of course, danger of infection from a pool used by many in which the bacterial content is not frequently destroyed or greatly reduced by some adequate means. Bunker argues that, as filtration in the manner in which it is usually employed yields only partial purification, the alternative seems to be disinfection. Disinfection by heat is out of the question on account of the expense. Disinfection of sewage and drinking water by means of chemicals has been tested at the Massachusetts Institute of Technology and at Experimental Station of the Ontario Board of Health at Toronto and at both places hypochlorite of lime was found to be a satisfactory disinfectant of drinking water. Furthermore, in parts of England and of the United States and in Montreal and Toronto, the same chemical used on a large scale has acted efficiently in rendering the public water supply free from hurtful germs. Hypochlorite of lime was used with equal success as a purifier of the water of the swimming pool at Brown University. The strength employed was 1 part available chlorine in 2,000,000. After the hypochlorite had been in the pool for one hour complete sterility of the water was effected. The pool remained practically sterile for four days, when the count began to rise. There was no odor and no perceptible taste, so that it may be asserted that hypochlorite of lime is an efficient sterilizer of swimming pools.

Effect of Lipoids on the Toxicity of Strychnine.

The term lipoid is relatively new. Formerly lecithin was considered as the only carrier of phosphorus. Now it is known that there are several lecithins, and they form only a part of the group of phosphorized lipoids. Lipoids are found in all the organs, and their proportion is variable. There are several groups, but the most important, the one in which lecithin belongs, contains nitrogen and phosphorus. Another group, without either of these elements, includes cholesterin. The brain is the organ that contains the most lipoids. Etienne Boissart, writing in *Le Nord Médical*, for September, 1910, gives the results of some personal studies of the attenuation of poisons, especially strychnine, by the lipoids lecithin and cholesterin. For some years work has been done with the object of determining the reason of the protective powers against poisons that are present in all the organs of the body. Bang and Forssmann have shown that the lipoids provoke the formation of antibodies. Emulsions containing lecithin and cholesterin possess immunizing power against the virus of rabies, against tuberculosis, and against typhoid fever. Pyocyanase, formed from the filtration of *Bacillus cæruleus*, arrests the development of microbic cultures by the action of the lipoids it contains. It seems likely that the defense of the body against infection is due to the presence of lipoids in the various organs. They also diminish the poisonous power of some chemical substances, notably the narcotics and other alkaloids. In the author's experiments lecithin and cholesterin were injected into guinea pigs in the same emulsion with strychnine, and it was found that the poisonous action of the strychnine was destroyed. Lecithin is the more powerful of the two substances in this respect, but a mixture of the two, Boissart says, has a stronger antitoxic action against strychnine than either alone.

Mutation of Species Among the Staphylococci.

The question of possible mutations among species is actively debated throughout the entire world of animal and plant life and not a few such possibilities have been suggested by bacteriologists. The question of mutation is naturally germane to that of the sudden creation of new species. The advocates of mutations among bacteriologists are thus far in the minority, for conservative authorities are able to throw doubt, to say the least, upon such claims. Thus the recent assertion that trachoma bodies represent a mutation of gonococci seems to have been successfully controverted by arguments showing that nothing more than a symbiosis is present. In a recent number of the *Muenchener medizinische Wochenschrift* (January 31) Dr. Palier of New York contributes a brief note relating to a supposed transformation of *Staphylococcus aureus* into *S. albus*. In an examination of a cancerous patient's gastric juice made at the Berlin Hygienic Institute a pure culture of the *S. aureus* was obtained. The author kept the culture for several years and in the meantime brought it to New York. No attempts were made to produce new cultures until nearly a year had expired. The agar of the first culture had dried and the first attempts to produce new cultures failed. The dried culture was then liquefied with sterile water; and further inoculations of media proved abundantly successful. But instead of the golden staphylococcus *S. albus* was found in pure culture. The author believes that the drying of the culture caused a change in its color. The question of actual mutation is not followed up, but the author suggests that all classifications of bacteria based on color are fallacious.

Relation of Public Health to Industrial Diseases.

At a meeting of medical officers of health held in London, on January 13, the report of which was published in the *Lancet*, January 21, the relation of public health to industrial diseases was discussed. Mr. W. F. Dearden opened the discussion and drew attention to the fact that the excessive mortality from certain diseases which afflicted work people engaged in particular industrial pursuits must point to the existence of some method of causation common to each industry concerned, whether or not this be directly or indirectly attributable to the trade process itself. There was one outside factor, however, alcoholism, which appeared to pick out certain trades in the exercise of its deleterious effects. Workers subject to excessive heat, as in glass works and rubber works, were, on account of the thirst created, addicted to the use of alcohol. The alcoholic tendency of printers, hatters, and shoemakers was well known. Waterproof cloth spreaders who were subject to naphtha fumes were very rapidly affected by alcohol, and it was suicidal for workers in lead to indulge in the drink habit. The direct influence of trade processes on the production of disease was particularly marked in dusty occupations. Another way in which industry affected public health was the production of a special liability to incapacity and death as the result of accident. The investigations by certifying surgeons of cases of anthrax, plumbism, or arsenic poisoning contracted in a factory or workshop were of great value, and had given information of service in demonstrating the necessity for supervision of the processes.

A Martyr to Science

Dr. Edward F. Ashley, bacteriologist of the New York Quarantine Service, died on Tuesday of this week from cerebrospinal meningitis. A few days ago a vessel arrived from Greece with several cases of this disease among the immigrants. The passengers were detained and one of them died. Dr. Ashley had been making cultures from the secretions and spinal fluid of the other patients and performed the autopsy on the one who died. On Sunday, the day following this autopsy, the first symptoms manifested themselves, and on Tuesday he died. Dr. Ashley was 35 years old, a graduate of the Yale Medical School in 1900, and an ex-member of the staff of the New York City Hospital. He was an earnest worker, devoted to his science, and gave promise of notable achievement had his life not been so prematurely ended.

News of the Week.

"Puck's" Fight for Humanity.—Three weeks ago we called attention to a strong cartoon in our entertaining contemporary, *Puck*, in which the cause of experimental medicine was set forth in a striking way. In the current issue, March 22, the journal renews the attack in another double-page cartoon. This represents a building on fire, the flames being disease against which an extinguishing stream of knowledge is being directed. Below the burning building is held a vivisectional research life-net to save a woman with child in arms jumping from above. The scientific experimenters who are holding the net and those directing the stream against the flames are harassed by a mob of spinsters, with the feathers of slaughtered birds in their hats, and of ignorant weaklings of the other sex, one of whom by the axe of legislation is trying to cut the hose. Yet they hold their ground and the net will save the child. *Puck* deserves the thanks not only of the medical profession but of all other humane persons for its fight in the cause of truth. Another cartoon on vivisection is announced for the issue of April 5.

Medical Legislation.—*For Clean Bakeries.* A bill recently introduced into the New York State Legislature makes all bakeries throughout the State subject to the provisions of the factory law, and gives to the State Commissioner of Labor the power to close bakeries found to be unsanitary. The bill regulates what may be regarded as the proper amount of light and air, drainage, and running water, and provides that no person shall be allowed to sleep in a bakery and that no birds or other animals *except cats* shall be allowed therein.

To Investigate Vivisection. The New York Senate Judiciary Committee on March 14 reported favorably Senator Bayne's bill establishing a commission to investigate the practice of vivisection in the State, and to report to the Legislature in 1912. The bill provides that the commission shall consist of one member of the Senate, one member of the Assembly, two physicians, two members of humane societies, and one member at large, all to be appointed by the Governor. The commission is to serve without compensation from the State.

Anti-Vaccination. The legislative committees on public health of New York gave a joint hearing on March 16 on the McManus-Boylan bill, which is designed to exempt from compulsory vaccination the children of those who object to the procedure. The bill was introduced at the request of the anti-

vaccination societies, a tenet of whose faith is that those who have "conscientious scruples" against vaccination should be allowed to overlook their obligation to the community as a whole.

Sale of Hypodermic Needles. Assemblyman Boylan has introduced into the Legislature a bill providing that no hypodermic syringes and needles designed for the injection of opiates shall be sold at retail without the written order of a duly licensed physician or veterinarian, and that each sale shall be registered with the name and address of the buyer. Mr. Hamilton Wright, Federal Opium Commissioner, has recently stated that "Uncle Sam is the worst drug fiend in the world," consuming yearly more opium than China or any other nation. In one form or another 500,000 pounds of opium are used annually in the United States, about one-hundredth of which is dispensed by the orders of physicians.

California Medical Examiners. The California Senate on March 7 passed a measure described by the newspapers as designed to "break up the medical trust," whatever that may be. It provides that the Governor shall appoint the State Board of Medical Examiners without being limited in his selection to the nominees of the various medical societies, as has previously been the case.

Revenue Tax. The Alabama State Legislature on March 15 adopted a section of the Revenue Bill placing an annual tax of $5 each on doctors and lawyers in the State. It is estimated that the revenue from this source will be about $50,000 a year.

Wood Alcohol.—Commissioner Lederle of the New York City Department of Health has warned the public, particularly of the lower East Side, against the danger from the use of wood alcohol which is mixed with cheap drinks by unscrupulous and criminal proprietors of barrooms and by certain representatives of the class of itinerant venders who go about the East Side selling "Weisse Schnapps" and other liquors from baskets. Several cases of blindness from drinking wood alcohol were recently reported and immediate investigations were made by the Health Department, with the result that three persons were arrested and accused of selling such drinks. Of these, the case of one is still pending, one was fined $75, and the third was acquitted. The department hopes for the cooperation of all physicians in promptly reporting any suspicious cases of blindness following the use of low-grade liquors.

Sanitary Drinking Fountains.—The Board of Education of New York is taking steps toward the installation of sanitary drinking fountains in the public schools to replace the common drinking cups now in use. A type of fountain which it is thought will prove satisfactory will shortly be placed in fifteeen schools in Manhattan, ten in Brooklyn, four in the Bronx, seven in Queens, and three in Richmond. The Vermont State Board of Health has recently adopted a regulation prohibiting the use of the common drinking cup in all public places, parks, fountains, school houses, factories, mills, workshops, libraries, public halls and other public buildings, railroad stations, and railroad trains, on and after May 1, 1911.

Ambulance Crash.—An ambulance from St. Vincent's Hospital, Livingston, Staten Island, was struck by an automobile belonging to the New York Department of Health, in which Dr. Walter Bensel was riding, on March 16, and was overturned. Dr. Tackhard, who was in the ambulance, which was answering a call, was thrown out and seriously injured.

Sanitation of Army Camps.—The recent mobilization of troops along the Texas border line has called attention to sanitary arrangements in army camps. At present the health of the troops is said to be excellent, though one case of smallpox, several cases of diphtheria, and a number of cases of measles and mumps have occurred and are under quarantine. No case of typhoid fever has appeared, but the lesson of the Spanish War has not been forgotten and the Secretary of War has directed that every member of the command, officers and privates, shall take the inoculation treatment as a preventive against the disease. The arrangements for the disposal of sewage and of refuse from the kitchens are in good shape.

Some amusement has been caused by the issuance of an order directing that each soldier in camp shall take a bath in the barracks at Fort Sam Houston at least twice a week, and that organization commanders shall take the necessary steps to insure the carrying out of the order.

"English Grippe."—Buffalo, N. Y., reports a serious epidemic of "English Grippe," which has attacked a large number of persons, both adults and children. During February ten deaths were ascribed to the disease, but no fatalities have occurred so far this month. Children are said to be especially susceptible and a large falling off in school attendance has been noted.

Ravages of Plague.—The latest estimates of the victims of the plague in China place the number of deaths since the beginning of the epidemic at over 20,000 in the Province of Harbin alone. Satisfactory statistics for the entire Empire are not possible. In India also the plague, which is practically always active, has been especially virulent this year, and the number of deaths during February is placed at the almost incredible figure of 88,498. One case of plague has appeared in Port of Spain, Trinidad, according to advices received in Washington on March 15.

From England comes the report of a mysterious disease among bees in the apiaries in that country, which has been especially severe of late. It is asserted that the bodies of the dead bees have yielded bacilli similar to the bacillus of bubonic plague, and that the infection may prove to be a variant of the human disease.

Meningitis from Greece.—The Greek steamship *Patris*, arriving in New York on March 12, reported six deaths on the voyage among her 689 steerage passengers, three of whom were buried at sea. The bodies of the other three were brought to port, and autopsies and bacteriological examination showed that the cause of death in all these cases was spinal meningitis, the same disease probably having caused the deaths of the other three, since all had occupied the same compartment. Five other passengers were removed from the liner to Swinburne Island because of illness, and the ship was detained at Quarantine until a thorough inspection revealed no other suspicious cases. It is reported as probable that a representative of the Public Health and Marine-Hospital Service will be assigned to Quarantine to assist Health Officer Doty in his investigation of cases of meningitis coming from Greece, of which there have been a considerable number recently.

Schools Closed.—Because of the prevalence of

scarlet fever in Roselle, N. J., the public schools as well as the Sunday schools have been ordered closed for two weeks.

A few cases of the same disease at Bryn Mawr College, Philadelphia, made it seem advisable to suspend the sessions of the college and to quarantine some of the residence halls and the infirmary.

War on Mosquitos.—The State Entomologist of New Jersey and the Hudson County Board of Health have started the work of draining the Hackensack Meadows so that the thousands of embryo mosquitos may be destroyed before the coming of warm weather. In Bayonne, N. J., the Board of Health has also begun the extermination of the pests by soaking the breeding places with oil, which is furnished free of charge for the purpose by the Standard Oil Company.

Galton's Eugenics Fund.—Prof. Karl Pearson, now professor of applied mathematics at the University of London, is reported as likely to be the first occupant of the chair of eugenics established in the university by the bequest of the late Sir Francis Galton. It is planned to extend the knowledge of eugenics by publications and lectures as well as by professional instruction, and by experimental and observational work. A central office will probably be established in the department to embody one of Sir Francis' most cherished schemes, which was to make available past history concerning any family or stock about which information might be desired.

Bequests to Charities.—The German Hospital, New York, receives a bequest of $250, and the Lutheran Hospital one of $100, under the will of the late Mr. Henry Roux.

Dr. James C. Hepburn of East Orange, N. J., the oldest living alumnus of Princeton University, celebrated his ninety-sixth birthday at his home on March 13. Dr. Hepburn was graduated from Princeton in 1832, having entered when he was only thirteen, and from the Medical Department of the University of Pennsylvania in 1836, and for many years served as a medical missionary in Singapore and in Japan. On his ninetieth birthday he received the decoration of the Imperial Order of the Rising Sun from the Emperor of Japan.

Dr. Leonard Weber of New York recently celebrated the fiftieth anniversary of his graduation as a doctor of medicine from the University of Erlangen, Germany, receiving on the occasion a renewal of his diploma from the university and a letter of congratulation and appreciation of his activities as a practitioner of medicine. Dr. Weber was also made a professor emeritus in the New York Post-Graduate Medical School in which he has taught since 1895.

Dr. George O'Hanlon has been appointed by the trustees of Bellevue and Allied Hospitals medical superintendent of Bellevue Hospital to succeed Dr. W. H. Smith who goes to the Johns Hopkins in Baltimore. Dr. O'Hanlon is a graduate of the College of Physicians and Surgeons of Baltimore, and has been for the past year first assistant superintendent of Bellevue.

Health Bulletin.—The first number of the Monthly Bulletin of the New York City Department of Health for January, 1911, contains an interesting report on the health of the city during the years 1868 to 1910, showing a gradual but almost unbroken decline in the death rate from 28 per 1,000 in 1868 to 16 per 10,000 in 1910. The figures cover only the present boroughs of Manhattan, Bronx, and Brooklyn, statistics for the other parts of the city during the early years not being available. The Child Welfare Exhibit, recently held in the 71st Regiment Armory, is described in another article, and a very complete summary of the work of the various divisions of the Sanitary Bureau for the years 1909-1910 is also included, as well as a series of comments upon the vital statistics of the city for the past year. The matter is all presented in interesting form, and there is no doubt but that the bulletin will attain a wide circulation and will become a useful factor in public health work.

III Internationaler Kongress für Wohnungshygiene.—The sessions of the congress will be held in Dresden from October 2 to 7, 1911, under the presidency of Geb. Medizinalrat Prof. Dr. Renk of Dresden. The general secretary of the congress is Dr. Med. Hopf, Dresden, Reichsstrasse 4 II.

Iredell-Alexander County (N. C.) Medical Society.—At the annual meeting held in Statesville on March 6 the following officers were elected: *President,* Dr. M. R. Adams; *Vice-President,* Dr. R. S. McElwee; *Secretary-Treasurer,* Dr. J. E. McLaughlin; *Delegate to State Society,* Dr. T. E. Anderson.

South Carolina Medical Association.—The annual convention will be held in Charleston on April 19, 20, and 21 under the presidency of Dr. James H. McIntosh of Columbia.

Winnebago County (Ill.) Medical Society.—Officers for the ensuing year were elected at the annual meeting at Rockport on January 10 as follows: *President,* Dr. W. H. Fitch; *Vice-President,* Dr. A. C. Eakin; *Secretary-Treasurer,* Dr. F. W. Hanford.

Omaha-Douglas County (Neb.) Medical Society.—At the annual meeting at Omaha on January 11 the following officers were elected: *President,* Dr. Leroy Crummer; *Vice-President,* Dr. B. W. Christie; *Secretary,* Dr. R. R. Hollister; *Treasurer,* Dr. Millard Langfeldt.

"With Peary on the Dash for the Pole."—Dr. J. W. Goodsell will deliver a lecture at the New York Academy of Medicine, under the above title, on Thursday evening, March 30, 1911, at 8:30, to which the public is invited.

The XVIIth International Congress of Medicine will meet in London during the summer of 1913, the exact date to be determined at the meeting of the International Permanent Committee, which will assemble for the first time in London on April 21 and 22, 1911. At this meeting the list of sections of the congress will be compiled and any propositions concerning the arrangement of the sections may be sent before April 1 to Prof. H. Burger, Vondelstraat 1, Amsterdam, the General Secretary of the Permanent Committee, or to the Bureau of the Committee, Hugo de Grootstraat 10, The Hague. The committee will be glad to consider any suggestions as to the organization of the congress.

The Late Dr. Janeway.—At the New York Academy of Medicine on April 6, 1911, a meeting will be held in memory of the late Dr. Edward G. Janeway, at which Dr. William H. Welch of Baltimore, Dr. Abraham Jacobi, Dr. Francis Delafield, Dr. Charles F. Chandler, and Dr. Joseph D. Bryant will speak.

The Late Dr. Stanley Douglas Curran.—At a meeting of the faculty of the University and Bellevue Hospital Medical College, held March 15, 1911, the following minute was adopted: "The Faculty

of the University and Bellevue Hospital Medical College desire to express their appreciation of the services of Dr. Stanley Douglas Curran, who died in New York City, February 4, 1911. Dr. Curran became connected with the college as assistant attending physician to the class of Internal Medicine in the College Clinic in 1902. In 1903 he was made full attending physician and continued in this position until his death. He was a most faithful and conscientious attendant. His sympathy with and careful examination of the poor who came to the clinic soon won their confidence and his class became one of the largest in the clinic. In 1904 he was made instructor in Physical Diagnosis and continued as such until his death. He was a teacher of marked ability and was always enthusiastic in his work. In the death of Dr. Curran the college has lost a loyal member of its teaching staff and the poor of the city one who devoted the best part of his strength and life to their welfare. EGBERT LEFEVRE, *Dean.*"

Dr. Beverley Robinson writes: "The sad death of my dear friend and former associate, Dr. Stanley Curran, came as a great shock. He and I worked together for many years at the Medical Clinic of Bellevue University Medical College, New York City, and I learned to know his keen medical acumen, as well as his accuracy and faithfulness of service. In private practice he was everything the conscientious, devoted physician should be; and in saying this I speak of what I know in those cases where we counseled together. What I have written is but an imperfect appreciation of a most loyal comrade who was doing his duty well and nobly in a profession practised by him with highest ideals. Peace to his ashes!"

Obituary Notes.—Dr. WILLIAM WARREN POTTER of Buffalo, N. Y., a graduate of the Buffalo University Medical College in 1859, a surgeon in the New York Volunteers during the Civil War, a member of the American Medical Association, the New York State and Erie County Medical Societies, the Buffalo Medical Surgical Association, the Buffalo Obstetrical Society, and the American Association of Obstetricians and Gynecologists, of which he had been secretary since 1888; president of the State Society in 1891, and president of the Section of Gynecology and Abdominal Surgery of the First Pan-American Medical Congress in 1893; president of the New York State Board of Medical Examiners, and consulting surgeon at the Buffalo General Hospital, died at his home on March 14, aged 72 years. Dr. Potter had edited the *Buffalo Medical Journal* since July, 1888, and also edited the annual volume of the Transactions of the Association of Obstetricians and Gynecologists.

Dr. BARTLETT N. TORREY of Detroit, Mich., a graduate of Washington University Medical Department, St. Louis, in 1874, formerly manager of the Omaha General Hospital, and a member of the American Medical Association, died at his home on March 3, aged 65 years.

Dr. THEODORE BACMEISTER of Toulon, Ill., a graduate of the Hahnemann Medical College and Hospital of Philadelphia, died at his home suddenly on March 8, aged 80 years.

Dr. JOHN H. SACKRIDER of East Randolph, N. Y., a graduate of the Medical Department of the University of Buffalo in 1878, and a member of the New York State and Cattaraugus County Medical Societies, died at his home on March 12 after a long illness, aged 63 years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent)

SMALLPOX OUTBREAK—INAUGURATION OF ENTOMOLOGICAL WORK AT THE SCHOOL OF SCIENCE—MALIGNANT DISEASE OF THE ESOPHAGUS—OBITUARY.

LONDON, March 3, 1911.

THE outbreak of smallpox is beginning to excite the attention of the public, for it displays a tendency to spread beyond the district where it first appeared. Already eight metropolitan boroughs have sent a case or two to the hospitals. Yesterday four new cases were reported and one death, the third since the beginning. Altogether there have now been forty-nine cases and forty-six of them are under treatment. Dr. Thomas, medical health officer for Stepney, has reported to his health committee the steps he has taken to prevent the spread of the disease by tracing out the contacts which in so crowded a district is no easy task. Of six cases reported to him of children under eight none had been vaccinated and one died; of fourteen cases between eight and thirty, two had never been vaccinated, twelve had been in infancy, and none revaccinated; of thirteen cases between thirty and sixty all had been vaccinated in infancy, but none revaccinated; of three cases above sixty the same statement applies and one of them had died.

In the epidemic of 1902 there were 7,700 cases, the mortality ranging from one in ten for the vaccinated to one in three for the unvaccinated. Yet all through the interval the anti-vaccinationists have been alarming timid mothers with untrue statements about the risks and dangers of the preventive. The present outbreak originated in the precise locality as did the last epidemic and yet it seems that the neglect of vaccination has been even greater than in other districts. It is estimated that at present 25 per cent. of London children are vaccinated and in one East End union no less than 50 per cent. The authorities of the Jews' Free School are having all the scholars whose parents do not oppose it vaccinated or revaccinated.

At the Royal Sanitary Institute Professor Kenwood has given a lecture on infectious diseases to sanitary officers and of course referred to the outbreak in which he deprecated the legislation which has so greatly tended to the neglect of protection. Parents have only to go to a justice's house and say they have a conscientious objection when the certificate of exemption is granted.

The education committee spent a couple of hours on Wednesday about a proposal that a schoolkeeper or caretaker when a case occurs must discontinue duty and be vaccinated within twenty-four hours. Of course some members called this unjustifiable and even monstrous. It was a question of fair play, said one, to those who did not believe in vaccination. Of course he cared nothing about fair play to the immense majority who did and who have to be exposed to the risk. Fight for faddism at all costs seems the motto of faddists. After an hour's adjournment it was agreed that if not vaccinated the worker must not return until the medical officer permitted, but should be paid his wages all the time. A nice holiday at ratepayers' expense!

Yesterday Mr. Maxwell-Lefroy, imperial entomologist to the Indian Government, inaugurated by

a lecture a course of study in practical entomology at the Imperial College of Science and Technology. This departure will doubtless be of the greatest importance to our schools of tropical medicine, but the work is not to be confined to any department. In research respecting insect pests we have been hitherto much behind. It is true that good work has been done by doctors in the tropics, but only a very small number have had full knowledge of entomology and there has been no such opportunity of training as exists in the United States. The deficiency will now be supplied in consequence of a munificent offer of Mr. Andrew Carnegie to defray the expenses incident to sending three or four young men to the United States to receive a thorough training in the practical methods of dealing with noxious insects which have proved so valuable in your country. It is hoped this will lead to a proper appreciation of the value of economic entomology. The first step would be the establishment of experimental stations where the requisite field training could be obtained and collections of insects made. Something of the kind has indeed been attempted by enthusiastic doctors in the tropics and medicine has been greatly advanced by them. But the committee of the Imperial College on entomological research takes a wider view and has already accomplished something. Two traveling entomologists have been sent to traverse the whole of our colonies and protectorates in tropical Africa and to supply residents who can undertake such work with apparatus and practical instructions for collecting insects likely to be of importance. Such are now being regularly received at the natural history museum, identified by experts and distributed to universities, schools of medicine and science, and so on. Varied specimens are returned to the collectors for their future guidance.

Mr. Maxwell-Lefroy in opening the course said that in the last twenty years entomology had become an applied science, but the part it played in daily life was too little appreciated. Nothing was done here compared with the United States and India. He referred to the various insects which had cost so many millions to the various forms of agriculture in America and had been there so carefully and successfully investigated. Passing to the blood suckers he said the bedbug was under suspicion of carrying disease, the rat flea transmitted plague, and the big flies of the genus *glossina* carried the dreadful, fearsome sleeping sickness and allied diseases of horses, cattle, and dogs.

If these diseases were to be checked it could only be by dealing with the transmitting insects. No one could say what the future held for us, whether plague would return to Europe as it had done to India where in fourteen years it had destroyed 7,000,000 lives. He hoped we might never see that or any other insect spreading disease in England. The horrors in congested districts would be too appalling.

Sir E. Ray Lankester proposed a vote of thanks to Lord Cromer for presiding and remarked that our islands were in a favorable position and singularly free from insect pests. It seemed natural to turn to America for training, as there we had received phyloxera, Colorado beetle, and other pests. The vote, seconded by Professor Sedgwick, was carried with applause and Lord Cromer in reply testified to the good work of entomologists in keeping down malaria in Egypt.

An interesting account of work on malignant stricture of the esophagus was given in a paper at the Medical Society of London by Dr. G. William Hill and was illustrated by numerous .r-ray photos and epidiascopic drawings. Moreover, six patients were examined with the esophagoscope and in one the interior of the stomach was demonstrated by a new method of esophagogastroscopy (the Hill-Herschel method), those present having the opportunity of seeing the region of the pylorus.

Dr. Hill passed in review the various operations that had been tried for esophageal cancer, none of which have cures to their credit. The only one still practised to any extent was the merely palliative one of gastrostomy, but he believed that intubation and radium would in the near future prove better palliatives and restrict to a much greater degree the resort to gastrostomy. The use of palliative drugs was also considered. Iodine and its compounds, fibrolysin and serums are not of any value, even temporarily. Locally spirits of ether would break up frothy mucus by reducing surface tension; astringents, cocaine, adrenalin, turpentine, etc., were of little use, if any; anodynes, as morphine, chloretone, orthoform, might relieve pain when the disease was high up, but in the end we had to resort to hypodermic injections for very painful cases. For dilatation of the gullet above a stricture lavage served to remove decomposing food and glycerite of boric or carbolic acid and other disinfecting and deodorizing preparations might be of use. Hydrogen peroxide was contraindicated. Caustics were inadvisable even when applied endoscopically to tight strictures. Electrolysis, ionization, and carbondioxide snow had not yet had full trial. X-rays had been said to give relief in a few cases high up. Diet was, of course, of the greatest importance and would exercise the ingenuity of the attendant. Bougies have no doubt given relief, but are only safe in expert hands, but the introduction of the endoscope makes it much safer. Intubation has rendered periodical bougieing no longer necessary.

Dr. Hill reviewed the steps by which we have come to retain permanently an oroesophageal catheter in the passage, from Krishaber's recommendation at the Congress of 1881 of a small gumelastic feeding tube, through Symond's funnels, Berry's whalebone backed tube, and so on. Dr. Hill's own improvement is a styletted, red rubber, soft catheter with a backbone of soft silver or of whalebone which can be fastened to the teeth and is not easily ejected by coughing or vomiting. Patients can be fed through this tube with liquids and after the apparatus has been retained for a week or two the dilating bougie effect often enables them to swallow fluids or soft food beside the tube, sometimes even what may be termed solid food. In the most favorable cases the tube could then be removed until the dysphagia returned. In other cases the tube had to be permanently retained. Dr. Hill said he had thus treated a number of cases with excellent results and looked on gastrostomy as almost a thing of the past. His styletted tube was more easily introduced than its predecessors either with or without the endoscope. Feeding through a tube was permanently required whenever there was a communication between the diseased gullet and the air passages, and with it liquids could be poured directly into the stomach. For any case of stricture it could be used with advantage. The life of the tube varied from five to ten weeks.

Dr. Hill next proceeded to discuss the use of radium in the esophagus. He had worked in co-operation with Dr. N. S. Finzi, who possessed 205 milligrams of radium costing £3,300. Together they had treated twenty-two cases, using from fifty to twenty milligrams for twelve to twenty-eight hours, repeating in some cases as many as six times. They claimed four temporary cures, six cases remarkably improved, seven substantially improved. In five cases there was no benefit and in two of them which were advanced it seemed doubtful if they were not worse after one application.

Dr. St. Clair Thomson related two cases much relieved by Dr. Hill's treatment. Mr. L. B. Rawling preferred gastrostomy to anything. Mr. Tilley said if anesthesia was required in esophagus cases chloroform was better than ether. Dr. Finzi said the dose of radium for healthy mucous membrane was 100 milligrams for six or seven hours with a platinum shield one and one-half millimeters thick; for diseased membrane an exposure three or four times as long.

Dr. MacMunn, A.M., M.D., T.C.D., consulting physician to Wolverhampton Hospital and Orphanage, died on the 18th ult. He was lieutenant-colonel of volunteers and went to South Africa in the war on special hospital service. He took great interest in public work in the town where he practised for many years, became a J. P. for the county of Stafford and received other honors. With all this he found time for scientific work, as seen in numerous contributions to the Royal Society's *Proceedings* and the *Journal of Physiology*. His work on the "Spectroscope in Medicine" will be known to you as authoritative. Probably you also know his "Clinical Chemistry of the Urine."

Among other deaths of the past month were those of Dr. A. W. Thomas, many years surgeon to Wandsworth Prison, at the age of fifty. He had also had a similar appointment at Nottingham as well as to the police force of that town. W. R. C. S., 1884; M.D. Brux., 1887.

The death is announced of Dr. Edmund Shaw of Southport, where he had practised about forty years. Took the college diploma 1852 and M.D., St. Andrews, 1862.

Dr. Kennedy of Perth, I.P.H., M.O.H., died on the 16th, aged sixty, after a short illness. He was a Glasgow graduate.

TUBERCULIN TREATMENT OF PARESIS—SALVARSAN AND OPTIC NEURITIS—EFFECT OF BLOOD SERUM ON CARCINOMA CELLS—PANCREAS AND DIABETES.

VIENNA, March 3, 1911.

In the psychological clinic of the University and in the Government Insane Asylum experiments have been performed in the treatment of cases of general paralysis by means of injections of tuberculin, with the result that certain of these cases have been completely cured. These experiments began in the year 1907 at the instance of Prof. v. Wagner-Jauregg and were carried out by Prof. Pilcz of the University. One of the most important aspects of the cure was the fact that the patients were able to resume their occupations; as in the case of a physician, a pharmacist and a professor of gymnastics.

The substance injected was a mixture of one part tuberculin, four parts glycerin, and ten parts of water. This treatment was given to every alternate paralytic admitted to the asylum, while the others were treated according to the older methods. Favorable results were observed only in the case of those treated by means of tuberculin. It must be admitted that progressive paralysis occasionally shows a tendency to remain quiescent and some cases even spontaneously improve. Nevertheless, this is seen in only 1 or 2 per cent. of the cases, while in the case of the use of tuberculin 23 per cent. of the cases may be cured. The injections were employed exclusively in metasyphilitic cases, which showed febrile effects of the inoculation. The patients have been observed for three years following the treatment, at the end of which time they have still given evidence of complete cure. Many of them are today filling important and honored positions. It is true that paresis does not nowadays present itself in such severe manifestations as formerly. This is to be attributed to the more successful treatment of syphilis. Its effective control would signify a great advance in medical science.

E. Spitzer has reported a case of optic neuritis following an injection of salvarsan. The patient was a woman 23 years old, who, seven months after the primary infection, was injected with 0.4 gram of salvarsan. Five or six weeks later there occurred severe headache, and four days later flashes in the right eye, and the sensation of a veil covering it. Examination of the eyes showed normal sight on both sides, but on the right side there were optic neuritis, swelling, widening of the veins and narrowing of the arteries, clouding of the papilla, and small hemorrhages. The Wassermann reaction did not become negative until the following December. The question whether the optic neuritis was a toxic or a luetic manifestation remains open. To be sure there are cases in which the optic nerve is peculiarly sensitive to arsenic. In view of this fact one must be very cautious in the selection of cases suitable for the injection of salvarsan.

Prof. Dr. Kraus and E. v. Graff report the results of their investigations on the effect of placental serum upon carcinoma cells. E. Freund and Kaminer have established that normal serum destroys carcinoma cells, while the serum of those affected with carcinoma does not possess this property. If human blood serum is added to a mixture of carcinoma cells in a solution of sodium phosphate and if the entire mixture is kept at 37° C. for 24 hours, enumeration of the cells at the end of this time will show that 85 per cent. of them are destroyed.

The serum of blood obtained from the umbilical cord destroys only 10 per cent. of the cells, behaving like carcinoma serum. The serum of pregnant women in the early months of pregnancy behaves like normal serum, but with the advance of pregnancy this destructive power of the serum gradually diminishes. The serum of the new born behaves variously, sometimes destroying the carcinoma cells and sometimes not. The sera of animals show two types; the serum of rabbits and guinea pigs is destructive, while that of rats and goats does not possess this power. With respect to mouse carcinoma various sera behave differently.

Prof. Anton Weichselbaum presented before the Practitioners' Society a communication on the changes in the pancreas occurring in diabetes mellitus. He distinguishes between three forms of human diabetes. In the first form there is an hydropic degeneration of the pancreas, or an atrophy of the islands, occasioned by this degeneration. In some of the cases there is a greater or less atrophy of

the glandular parenchyma. This form of diabetes is peculiar to early life and is not associated with sclerosis of the pancreatic arteries. In this form there occur clinically the severe and severest cases, as would be expected from the widespread changes in the pancreas. Nothing definite is known about the cause of the hydropic degeneration. Possibly hereditary weakness or developmental anomalies of the islands of Langerhans play here a rôle so that these are easily affected by slight toxic agents. The second form of diabetes is characterized by chronic sclerosis and atrophy of the islands resulting from a chronic interstitial pancreatitis. This form of diabetes is found in later life, after the fiftieth year, and is most frequently associated with sclerosis of the arteries of the pancreas, which is not seldom a local manifestation of a general ateriosclerosis. There is sometimes a fatty infiltration of the pancreas, a so-called pancreatic lipomatosis, which in its pronounced forms controls the clinical picture, and then usually is associated with a general lipomatosis. In its clinical aspect the second form corresponds to the milder cases, in which the amount of sugar in the urine is slight, and the course of the disease is a very protracted one. To this form belongs the so-called fatty diabetes. The third form of diabetes is characterized by hyaline degeneration of the islands of Langerhans. It also selects the later years of life and is frequently associated with arteriosclerosis. It rarely occurs in its pure state, but is usually associated with the second form. Arteriosclerosis also plays an important rôle in this form. All those causes that are held responsible for arteriosclerosis must also be held responsible for diabetes. Chronic alcoholism is an important factor, evoking not only cirrhosis of the liver, but also chronic interstitial pancreatitis.

OUR LETTER FROM THE PHILIPPINES.

(From Our Regular Correspondent)

A POPULAR HYGIENIC EXHIBIT—STATISTICS OF INFANT MORTALITY—PHARMACEUTICAL INSTRUCTION — TUBERCULOSIS — CHOLERA — MINERAL WATER SUPERSTITION.

MANILA, February 5, 1911.

THE Bureau of Health is preparing a popular hygienic exhibit for the Philippine Carnival which is to be held in Manila from February 21 to February 28, 1911. It will consist, among other things, of an ordinary native nipa house, a native nipa house the way it should be constructed and maintained in order to avoid contracting tuberculosis and be hygienic in other respects. There will be models of the septic tanks which are being so successfully used in the Philippine Islands, and also of the new sanitary barrios or town sites which are being built in the city of Manila to replace the former unsanitary dwellings. Particular attention will be given to the nutritional value of foods, and many simple diets upon which good health can be maintained will be exhibited, the principal aim being to have these diets within the means of the average laboring man in the Philippine Islands. There will also be models of artesian wells, municipal sand filtration systems, and other exhibits of sanitary interest.

Recently a further study of the infant mortality in Manila has developed certain facts which heretofore have escaped attention. It will be remembered that the death rate among infants under one year of age has frequently been reported as 50 per cent. of the total number of deaths, which is a rate which ranks as high as that reported anywhere in the world. An examination of the statistics of the Bureau of Health shows that for the months of October, November, and December nearly half of this number were under six months of age and that they were born outside of Manila, that is to say, in the provinces. From this it is evident that they are not correctly chargeable to the Manila statistics, and when these deductions are made the infant mortality in Manila will approach closely to that of other cities of similar size. An investigation is now being made to ascertain if possible why so many of these children are brought to Manila.

An investigation was recently made by a committee from the College of Medicine and Surgery of the University of the Philippines to examine the facilities that are afforded by the different schools of pharmacy in Manila to teach pharmacy, and also to report upon the character of examination conducted by the Board of Pharmaceutical Examiners prior to issuing a license to practice. The report showed that with the exception of the Santo Tomas School the facilities were entirely inadequate and in some instances the equipment which they did have was not even used. Much complaint has arisen over the fact that since the new Board of Pharmaceutical Examiners has been appointed, over a year ago, only two candidates of the many who applied were able to pass. The examination questions of the Pharmaceutical Board were found to be entirely fair and of such character that any graduate of the average school in Europe or America would have no difficulty in making a passing mark. The committee found that these complaints had no just foundation. It may be remembered that the former board passed large numbers of candidates and was finally dismissed on account of the irregularities which were discovered.

In view of the fact that the course at the Santo Tomas School also leaves much to be desired, the committee recommended that a college of pharmacy be begun by the University of the Philippines.

The experiment of treating incipient cases of tuberculosis at Baguio, which has an elevation of 5,000 feet, has now been under way for nearly a year, and the results have been very encouraging. The records show that three of the six cases have apparently made a complete recovery and the remaining three show signs of great improvement, and the prognosis is favorable. This would indicate that the treatment of pulmonary tuberculosis at high altitudes in the tropics affords as much hope of success as in the temperate zone. The sanatorium at the outskirts of Manila which was opened September last now has thirty patients, the majority of whom are improving. The average gain in weight is about three pounds per week during the first month of their admission. This is not as favorable a record as at Baguio, yet on account of the accessibility of this camp it will probably be a greater factor in combating tuberculosis than Baguio.

A few cases of cholera have again been reported in Bulacan Province near Manila. Suspicious cases were reported from time to time during the early part of January. Last week bacteriological examination of specimens from one of these cases revealed the spirillum of Koch. The Bureau of

Health has taken steps which it is thought will result in suppressing the outbreak. The first cases occurred in one of the suburbs of Obando, upon a small island the inhabitants of which are principally engaged in gathering oysters and other shellfish for the Manila market.

The readiness with which the Filipino people attribute wonderful curative properties to water supplies that differ slightly from the normal was again well shown at the town of Mariloa, in Bulacan Province. While boring an artesian well a good supply of water was struck which is lightly charged with hydrogen sulphide. This news spread rapidly, a bath house was immediately constructed, and many hundreds of people came daily from far and wide to bathe in the water and to drink at the springs.

On the Dependence of Intestinal Indigestion on Gastric Disturbances. A. E. Austin.
On the Possible Effect Upon the Auditory Labyrinth of the Ehrlich-Hata Remedy in the Treatment of Syphilis. Professor G. Alexander.
The Treatment of Fistula in Ano. T. C. Hill.
Salvarsan in the Treatment of Chronic Pemphigus. R. L. Sutton.

Intestinal Indigestion and Gastric Disturbances.—A. E. Austin states that diarrhea does not always accompany an achylia nor a hypochlorhydria, nor, from the presence of connective tissue in the stool, can one always deduce the state of the gastric juice. Furthermore, while hyperchlorhydria is usually accompanied by constipation, one may have diarrhea, or the bowels may be regular, while with gastric myasthenia constipation is the rule, as it is in hypersecretion. A functional chronic catarrh of the small intestine may exist associated with any of these gastric conditions, with excessive or no free HCl and with increased or impaired motility, so that one can only say that improperly prepared food is poured into the small intestine, which either on account of this extra burden or on account of some antecedent inflammatory disturbance undergoes a functional impairment that usually manifests itself by the increased motility.

Salvarsan and the Auditory Labyrinth.—Professor G. Alexander recommends caution in the use of salvarsan in cases of acute syphilitic disease of the auditory nerve, especially in the presence of acute or chronic disease of the auditory nerve in cases of recent syphilis, as here it is to be feared that the ear symptoms will be made worse. It appears to make no difference whether the disease of the auditory nerve is of itself of syphilitic origin or not. An unfavorable influence is also to be feared in cases of acute syphilitic affection of the auditory nerve in old cases of syphilis or latent chronic syphilis. In cases of hereditary syphilis, in the presence of acute manifestations of trouble with the auditory nerve, one ought to wait before giving the injection of salvarsan. On the other hand, there are a large number of cases of ear disease in which the previously described dangers from the arsenobenzol injection cannot be considered as dependent upon it. Here belong the cases of chronic syphilitic affection of the auditory nerve, with slight diminution of hearing power and considerable tinnitus, as well as the cases of chronic labyrinth dizziness. Finally, salvarsan has a good effect in cases of chronic labyrinth disease in chronic syphilis.

Treatment of Fistula in Ano.—T. C. Hill discusses the various methods of treatment, namely, (1) excision with immediate suture; (2) injections of bismuth paste; and (3) incision.

Salvarsan in Chronic Pemphigus.—R. L. Sutton reports the rapid improvement following the use of this drug in a case of chronic pemphigus, a result that apparently points in the direction of a parasitic factor in the etiology of this condition.

Salvarsan.—H. Fox and W. B. Trimble conclude that this drug is a remedy of great power in causing certain manifestations of syphilis to disappear. Its symptomatic effect is perhaps most strikingly shown in lesions of the mucous membranes. It seems to be of particular value in malignant precocious syphilis, in threatening destructive processes, and in cases that are refractory to mercury. A final opinion as to the permanence of its action can only be given after a lapse of several years, during which time both clinical manifestations and Wassermann reaction must be carefully observed. Relapses are frequent and seem to occur more frequently than after treatment with mercury. Except in certain selected cases the authors do not think that salvarsan will replace the use of mercury. The disagreeable by-effects from its use have in their experience been generally transitory and of little importance. According to present knowledge the most efficacious form of administration appears to be an intravenous injection followed in four days or later by an intramuscular injection of an oily suspension.

Apparatus for Salvarsan.—A. L. Wolbarst describes a portable sterilizer containing all the necessary apparatus for the aseptic administration of salvarsan at the bedside.

Emulsion of Salvarsan.—J. G. Burke suggests a 10 per cent. lanolin in olive oil emulsion, as this quantity of lanolin has been found sufficient to hold the 606 in suspension, and it is known from clinical experience that olive oil is well tolerated by the tissues, while the mineral oils are more or less irritants. The vessel containing this lanolin and oil mixture and a small mortar and pestle and the needle and syringe are all that are required. These should be sterilized and 2 c.c. of the oil placed in the mortar and then the salvarsan powder dropped into it from the vial in which it is marketed; this is stirred up into an emulsion and drawn up into a syringe; then 1 c.c. more of the oil is used to take up what is adhering to mortar and pestle; this is also drawn into a syringe and it is then ready for the injection. The total quantity injected is not much greater than that of an ordinary hypodermic syringe.

Adenoid and Tonsil Operations.—L. D. Alexander and J. T. Gwathmey describe the technique of their operations. The patient is anesthetized by the vapor or drop method of ether or chloroform. Any closed method puts too severe a strain upon the chest walls. The usual procedure is as follows: From three to six drops of chloroform, followed by as many of ether; then alternating, and changing entirely to ether as surgical anesthesia is reached. This procedure gets the patient under in from three to five minutes, and without any struggling. When surgical anesthesia is complete the patient's head is thrown back, catheters for the suction of blood from the operative field are placed, and gag and tongue depressor are inserted. The tonsil is grasped and drawn forward; the superior attachment is cut with scissors; the knife is then passed

behind the tonsil to its base, then in front similarly. The pillars are now separated with the separator, a fresh hold is caught with the other tonsil holder, the snare applied and the tonsil removed. An occasional swab is employed to remove clotted blood not sucked up by the catheters. The adenoids are then removed in the usual way. The average time of operation is eight minutes.

Tumor of Hypophysis.—F. J. Farnell reports a case of extracerebral tumor in the region of the hypophysis.

Colon Bacilluria.—J. Pedersen reports a case of this condition occurring in a girl twelve years old.

Effervescence Test for Gastric Acidity.—A. L. Benedict describes the use for this purpose of a saturated solution of sodium bicarbonate. In the clinical employment of the test the patient stands with the gastric area well exposed and is warned not to make a noise in his throat, not to breathe unless ordered to do so, not to rustle his garments, to swallow the solution, about 30 or 50 c.c., quickly at one gulp instead of sipping it and allowing it to settle. The room should be perfectly quiet, and the physician should be sure that the stethoscope is properly placed, firmly in contact with the abdomen, and held without danger of slipping of the fingers. Usually the best site for the stethoscope is about two inches to the left, in a line toward the axilla from the umbilicus, but care should be taken to get the stethoscope over the stomach and not merely where the stomach ought to be. If the stomach is much dilated and filled partly with liquid and partly with gas the sound is heard best at the surface level of the liquid.

Eradication of Plague.—C. W. Vogel states that the eradication of plague from urban communities may be succinctly stated to be dependent upon two main factors, the destruction of the rat population and the rat-proofing of all buildings of every description.

Phrenology.—J. Knott continues his article on this subject.

Cesarean Section.—By L. S. McMurtry. See Medical Record, January 28, 1911, page 175.

Mobilization of Joints.—A. C. Strachauer calls attention to the use of gradual strong flexion or extension by the application of rubber bandages of the ordinary 2½-inch kind. The manner of the application should be in accordance with the special indications and requirements of each case and should be so made that the contraction of the bandage takes place in the line of the desired increase of motion, *i.e.* in the line of normal movement. The method gives a gradual, even, confidence-forming tension and overcomes the voluntary and spasmodic contraction of the guarding, protecting muscles and brings about a mechanical stretching or relaxation. Slight pain and discomfort may be permitted, according to the patient's endurance, on the condition that the joint should not be tender on the following day. The first applications should be made every second day, after which they can be given daily. Joints with false or fibrous ankyloses in which there is no danger of activating a quiescent infection should be broken up under anesthesia, the reformation of such ankylosis prevented, and the mobility increased by beginning on the second day following the forcible procedure the application of the rubber-bandage method.

Control of Pasteurization.—G. Koehler and F. O. Tonney state that the proper control of pasteurization is imperative with the present intensive methods of dairying, favoring the spread of tuberculosis. It has been proved that the eradication of tuberculosis by killing off the diseased animals is impracticable and the methods of inspection of the sources of milk supply are inadequate. It is evident that the control of the marketing of pasteurized milk is still unsatisfactory, though the averages have been better than for preceding periods. The lesson is drawn that the temperature at which the product is delivered or sold should also be subject to control if a safe product is to be supplied.

Abdominal Injuries.—By H. H. Sherk. See Medical Record, Vol. 77, page 1069.

The Secret Commission Evil.—By J. P. Lord. See Medical Record, February 25, 1911, page 363.

Treatment of Anteflexion.—By H. T. Byford. See Medical Record, February 4, 1911, page 226.

Importance of the Autopsy.—Professor H. Chiari notes how important is the function of the pathologist in performing autopsies and how his calling is not only didactic but humanitarian. His work, therefore, deserves support and encouragement from all sides, and especially from the laity. The public must be made to appreciate to an ever-increasing extent the importance of pathological anatomy.

The Prostatic Utricle.—J. T. Geraghty states that the utricle can readily be the lurking place for infection, and, although the literature is full of references to the inflamed appearance of its orifice, no practical method, so far as the author has been able to learn, has been suggested of treating this sign. By means of a syringe he has found it not only feasible but easy to make injections directly into the utricular cavity. A straight No. 24 (French) urethroscopic tube with an external light is passed into the prostatic urethra beyond the verumontanum, which can be determined by the resistance encountered. It is then gradually withdrawn until the readily recognized verumontanum comes in view and its anterior face projects into the open portion of the tube and the utricular orifice directly appears in the field of vision. After gently swabbing the mucous membrane the tip of the syringe can be readily introduced, the contents of the utricle aspirated for microscopic examination, and injection made into its cavity. A weak solution of silver nitrate is usually employed for the latter and seems to give the best results. It is well to begin with 1 per cent. and gradually increase to 2 or 3 per cent. if needed, injecting very slowly and gently. With this strength the injection may be repeated at intervals of from five to seven days. Stronger ones should have intervals of two or three weeks. The conditions for which they are suggested are painful ejaculation, which may be due to the opening of the duct on the floor of the utricle, hematospermia, urinary dribbling, and some cases of posterior urethritis in which the infection seems to be kept up by the lodgment of germs in the utricle. This is probably the cause of many resistant cases. In some cases, particularly where the orifice is small, it is well to snip out a wedge-shaped piece of the utricular roof

to afford better drainage. This can be done by Young's scissors devised for excision of portions of the verumontanum.

Salvarsan.—J. L. Boehm describes a gravity apparatus for the intravenous injection of salvarsan.

Inspection of Oyster Beds.—C. A. Fuller reviews the legislation passed and proposed for the protection of the oyster grounds from contamination. The Federal Government has recently passed two laws affecting the shipment of oysters and their inspection in interstate commerce. The ultimate control of the oyster products, however, rests with the different States, and it is only recently that any measures have been taken to regulate the catch of oysters from polluted areas and to prevent the sale of polluted oysters.

The Plague in North China.—J. J. Mullowney presents the following data regarding the plague in North China: The disease started at Harbin. Up to January 24, 1911, there had been about 1,500 Chinese and 27 European deaths; two of the victims were physicians and one an assistant. The disease is mostly of the pneumonic and septicemic types. Inoculation with Haffkine's antibubonic vaccine seems to be of considerable value as a prophylactic measure. The administration of Yersin's serum does not seem to be of much value, although it should be said that it has not been given a full trial. It has been conclusively shown that the disease, in the pneumonic form, is transmitted by the sputum and by contact with persons sick of the disease and that the wearing of respirators is good prophylaxis. The rat or the rat flea does not seem to have nearly as much to do with the spread of the pneumonic type of the disease as it has in epidemics of the bubonic type. So far as the author is aware, this is the first definite epidemic of the pneumonic type of the bubonic plague. The disease spread along the line of railway traffic from Harbin to Mukden, to Shanhaikwan, to Tientsin and to Pekin and to several smaller places. It also reached Chifu, which is a seacoast town, probably through some Chinese coolies returning from the north in a Chinese junk or fishing boat.

Case for Blood Pipettes.—W. S. Sutton describes a convenient means of collecting and carrying pipettes and smears of blood.

Pneumococcemia.—E. A. Aronson and H. Olsan report a case of pneumococcus infection following scarlet fever in a child 4½ years old. The scarlatinal infection had preceded that of the pneumococcus by about two weeks. The latter was not in the usual form of pneumonia, but in that of a bilateral empyema, and was demonstrated by blood-cultures. While empyema is of frequent occurrence, it is usually unilateral, and the pus when it follows scarlet fever most frequently contains the streptococcus or staphylococcus. There was a possible metastasis to the face, as an abscess occurred in the right cheek, the pus containing a large number of saprophytic bacteria, and a blood-culture showed the presence of pneumococci. In these cases of double empyema, especially when so severe as in the case reported, the authors think the incision and drainage of one side at a time is the best method of procedure. If both sides had been opened at once in their patient it would probably have caused death. If the child's condition had not been so desperate rib resection would have been performed.

Fracture of the Clavicle.—S. Erdman calls attention to a former publication noting the fact that there is a distinct transmission of both voice and breath sounds, probably from the trachea, outward along the shaft of the clavicle. A fracture of the bone therefore should cause a break in the sound propagation, and this is found to be the case and may be utilized in diagnosis. In a series of fifteen cases reported in his former paper there was a complete loss of these auscultatory sounds on the injured side, in contrast to their presence on the other. In his former study he used the stethoscope. He has since used a simpler method, available in young children who cannot be made to whisper. It is the recognition of vocal fremitus by the palpating finger which can detect the cries of even the youngest child. The thumb or index finger of each hand is placed on the corresponding clavicle of the patient, without pressure, and gradually moved from near the sternal end outward symmetrically, while the patient repeats some sonorous word. With complete fracture the fremitus is suddenly lost or very greatly lessened at the point of fracture and beyond, and it is often possible to follow the obliquity of the line across the shaft at the point of fracture.

Tumor Implantation.—P. Rous and J. B. Murphy describe the results of their experiments in the inoculation of sarcoma into developing chick-embryos.

Primary Orchitis with Secondary Parotitis.—J. F. Torpey reports a case of this condition, the reverse of metastatic mumps.

Adrenal Stimulation.—W. B. Cannon and D. De La Paz have determined experimentally that emotional excitement causes a stimulation of adrenal secretion.

Paralysis of the Bladder.—H. J. Relihan and J. Simon report a case of this condition, in which the patient was operated on under the mistaken diagnosis of ovarian cyst with twisted pedicle complicated by pelvic infection. Catheterization had not been performed before operation. A trocar was introduced into the supposed cyst and three gallons of urine were withdrawn.

Enteritis from Trichocephalus Dispar.—B. N. Wade reports a case of this condition, which emphasizes the importance of examination of the stools as a routine procedure in cases of anemia when no cause is evident.

Some Mediastinal Affections. P. Kidd.
The Immunity Reaction in Diagnosis, Especially of Tuberculosis and Syphilis. W. d'Este Emery.
The Mechanical Treatment of Spinal Caries. H. I. Gauvain.
The Education of the Deaf; Its Present State in England with Suggestions as to Its Future Modifications and Development. M. Yearsley.
A Case of Suprarenal Apoplexy. R. Waterhouse.
Cranial Asymmetry Due to Postural Causes. H. Armstrong.
A Case of Rodent Ulcer of the Thigh. H. E. Friend and T. C. English.
Notes on a Case of Retention of Urine. G. W. Bury.
Infantile Diarrhea. W. Tibbles.

Mediastinal Affections.—P. Kidd reports the following unusual examples of mediastinal disease: 1. A case of substernal thyroid tumor simulating a mediastinal new growth. This had caused difficulty of breathing. Operative removal of the growth was followed by recovery. 2. A case of mediastinal cyst, possibly dermoid. 3. A case of mediastinal abscess perforating the trachea and esophagus and causing subcutaneous emphysema and cellulitis. 4. A case of mediastinal growth masked by pericardial effusion. 5. A case of mediastinal growth masked by pleural effusion. The last three cases came to autopsy. 6. A case of tuberculosis of the mediastinal glands followed by pleurisy with effusion; from the latter the patient recovered, but died several years later from tuberculous meningitis. 7. A case of tuberculosis of the mediastinal glands compressing the right bronchus. Recovery ensued. 8. A case of tuberculosis of the mediastinal glands involving the lung by direct infection through the bronchi. 9. A case of tuberculous abscess of the bronchial glands, with bronchopneumonia simulating acute tuberculosis; death resulted from septicemia. The history of these cases showed the inadequacy of the standard methods of diagnosis. While one can recognize with a fair degree of accuracy gross lesions of the mediastinal glands, moderate enlargements of these structures frequently escape observation.

Wassermann Reaction.—W. d'Este Emery describes the various methods of performing this reaction and presents an original method of determining it quantitatively. He lays down the following rules for the interpretation of the reaction: Early in the primary stage a negative result means nothing. In the presence of supposed secondaries the absence of the reaction is conclusive. If the disease is in a still later stage, but if there are lesions present and the disease, whatever it is, is progressive, then the absence of the reaction is almost conclusive proof that another diagnosis must be sought; the disease may be syphilis, but the chances are enormously against it. If the patient is supposed to be in the later stages of syphilis, but there are no symptoms or lesions apparent, the question of cure arises. If the reaction is present, even if only slight, the patient is not cured. If there is no reaction the question is more difficult. The author believes on the whole that one is justified in pronouncing him cured, but there is always the possibility that the case may be one of those rare ones which are supposed to occur in which no reaction is given at any time. A person with congenital syphilis may give the reaction for life.

Mechanical Treatment of Spinal Caries.—H. J. Gauvain states that in the treatment of acute spinal caries general rest should be enforced; absolute rest to the affected part is desirable; deformity should if possible be prevented; interosseous pressure at the site of the disease avoided, and muscular spasm overcome. These desiderata may all be obtained by keeping the patient recumbent, immobilized, and hyperextended, the hyperextension being in some cases aided by traction extension.

Education of the Deaf.—M. Yearsley continues his article on this subject.

Suprarenal Apoplexy.—R. Waterhouse reports the case of an eight months' old infant, with the following history: Previously in good health, he one morning became very drowsy; at 3 P. M. he vomited; at 3:30 P. M., on admission to the hospital, the infant was obviously very ill; complexion gray, eyes dull, breathing rapid, shallow and noiseless; temperature 100.4°, pulse 140, and respirations 72. Râles could be heard all over the chest, especially at the bases behind. The abdomen was soft and not tender. There were no signs of meningitis, and nothing abnormal was to be seen in the mouth or fauces. Two hours after admission an extensive eruption of purple spots and blotches appeared over the whole trunk, upper arms, and thighs. The temperature had fallen to 99.4°. The child rapidly grew worse, the face becoming cyanosed, and death occurred at 7:30 P. M., four hours after admission. There were no convulsions throughout. At autopsy the suprarenal capsules were striking objects, even before their removal from the body; of little more than normal size for a child of this age, they were both of a deep purple color and evidently the seat of hemorrhage. The extravasation of blood had taken place into both the cortical and medullary portions, but no bleeding had occurred into the adjacent tissues. Microscopically the structure of the medulla was seen to be completely destroyed and replaced by effused blood. The arrangement of the columns of cells in the cortex could be made out, but the cells themselves had largely disappeared, their nuclei alone remaining, while everywhere were to be seen large numbers of red blood corpuscles. All the other organs appeared natural.

Cranial Asymmetry.—H. Armstrong describes the following causes of this condition: Traumatism in parturition; cranial or intracranial disease; and posture. In a rachitic child, lying on its back, the face and the base of the skull are acted upon by gravity and are pulled downward away from the calvarium, which, supported by the occiput, lies on the pillow and can descend no further. This is the cause of the frontal prominence of the rickety head. In congenital torticollis a marked facial and cranial asymmetry is seen. The most marked examples of cranial obliquity occur as the result of nursing the infant at one breast only.

Rodent Ulcer of the Thigh.—H. E. Friend and T. C. English report a case of this condition, which because of its location is considered one of great rarity.

Retention of Urine.—G. W. Bury reports a case of uremia in a female patient thirty-seven years old. There was an enormous retention of urine in the bladder, which was not ruptured; the amount of urine withdrawn by catheter was 166 ounces. There was a rapid recovery of vesical tonus.

Infantile Diarrhea.—W. Tibbles classifies the causes as follows: Autogenetic—(1) gastroenteric catarrh, (*a*) acute, (*b*) chronic; (2) intestinal fermentation; (3) toxemia. Heterogenetic—(4) mechanical irritation; (5) nervous influences; (6) drugs; (7) improper feeding; (8) bacterial infection.

Dilated Stomach. A. F. Hertz.
Prevalent Rain-Bearing Winds and the Milk Supply of Manchester During the years, 1896-1909. W. Gordon.
The Diagnosis of the Commoner Causes of Chronic Jaundice. P. J. Cammidge.
Observations on the Urines of Marathon Runners. G. Chambers.
Intussusception of the Appendix. J. W. Thomson.
A Clinical Lecture on Chronic Traumatic Mastitis. G. L. Cheatle.
An Unusual Form of Perineal Hernia. A. G. Atkinson.

Dilated Stomach.—A. F. Hertz describes the causes and symptoms of dilatation of the stomach, and shows in some detail how recent researches on the motor functions of the stomach have made a more accurate diagnosis possible, and how the information obtained bears upon the treatment of the different forms of dilated stomach.

Rain-Bearing Winds and Milk Supply.—W. Gordon notes the fact that strong prevalent rain-bearing winds have a remarkable power of increasing the mortality from human tuberculosis. He shows also that they similarly influence the distribution of bovine tuberculosis and are thus an important factor in the milk supply.

Chronic Jaundice.—P. J. Cammidge states that by a timely and correct diagnosis, such as is possible from a careful consideration of the clinical history and symptoms, and the information to be obtained by a thorough analysis of the urine and feces, the complications and sequelæ likely to arise in cases of chronic jaundice, such as serious disease of the pancreas, cholangitis, cirrhosis of the liver, etc., may be avoided. Delay is always dangerous. A diagnosis of gallstones obstructing the bile duct, made on the clinical data and confirmed by an examination of the excreta, calls for immediate operation, as the only likely spontaneous cure is Nature's crude and dangerous remedy of making a fistula by which the stone may escape into the duodenum or elsewhere. Catarrhal jaundice very frequently clears up spontaneously, but if after six weeks' rest in bed, with dieting and medical treatment, the jaundice persists and the urinary "pancreatic" reaction is positive, it is advisable to invoke the aid of the surgeon to perform a short-circuiting operation to avoid further damage to the pancreas. In the last stages of malignant disease operation is only likely to shorten the brief span of life still left to the patient, but in the earlier stages much may be done to make existence more bearable by a cholecystotomy or cholecystenterostomy to relieve the intolerable itching of which complaint is chiefly made. At the same time it is well to bear in mind that many cases diagnosed clinically as inoperable carcinoma of the pancreas have been shown on chemical examination of the urine and feces, and by their after history, to be suffering from chronic inflammation of the gland capable of retrogression.

The Urines of Marathon Runners.—G. Chambers records the observations made on the urines of eight Marathon runners. After the race seven specimens of urine continued nucleoalbumin, albumin and globulin, and in the sediments hyaline and faintly granular casts, and epithelial cells. In three of the specimens there were red blood corpuscles.

Intussusception of the Appendix.—J. W. Thomson reports two cases of this condition.

Chronic Traumatic Mastitis.—G. L. Cheatle describes this condition as consisting of two or more painful, tender, and hard lumps in the breasts; the condition is worse at the menstrual periods. The main causes are corsets which have not been made upon hygienic principles.

Perineal Hernia.—A. G. Atkinson records an unusual form of this condition, in which the hernia would seem to have arisen from an abnormally deep vesico-uterine pouch, passing down between the urethra and vagina. From this the sac passed forward through the posterior wall of the urethra, being then extruded through the urinary meatus.

Berliner klinische Wochenschrift.

February 27, 1911.

Diabetes Insipidus.—Rosendorrff and Unna consider this affection from the points of view of differential diagnosis and therapy. It will be recalled that diabetes insipidus has largely been a clinical entity only, a mere polyuria or pollakiuria which might be due to the most diverse conditions. Thus it might be thought of only as a result of polydipsia, or an expression of a psychoneurosis. Some authors have looked upon it as a compensatory phenomenon of cirrhotic kidney, while others associate it with prostatic irritation. A division into primary and secondary types is inevitable, and we may exclude from consideration all of the latter. There remains a doubt as to whether a primary type of disease is always the same affection. The natural inference is this—that to produce an essential or primary polyuria there must be something to be eliminated; that is, some solid constituent of the urine, such as the chlorides. If such substances were not injected in excess, such an increased elimination would constitute an anomaly of metabolism. The authors evidently profess the belief that several factors must combine to produce a case; to wit, a nervous substratum and perhaps ingestion of an undue amount of chlorides—at least a reduction of the latter relieves the polyuria. Four cases are analyzed. All the patients were youthful and highly neuropathic. In one of the number there was a history of lues, but otherwise the neuropathy could hardly have had an organic substratum. In one patient there was an undoubted psychogenous polydipsia, so that the case was of secondary origin. In case II psychogenous polydipsia could be excluded. The patient appeared to have an alimentary chloruria, which was amenable to dietetic treatment; but the phenomenon was not pronounced. In the third and fourth cases the latter, while suggested, was still less in evidence. Doubts remain as to whether these cases could really be looked upon as an essential alimentary chloruria. If we cut down the salt in the diet of any individual he is less thirsty and excretes less salt and urine. In the diagnosis of diabetes insipidus much has heretofore depended on the low molecular concentration of the urine as shown by cryoscopy. In characteristic cases even feeding with a chloride-rich or a nitrogenous diet cannot bring the cryoscopic point within normal limits. The authors would therefore make of essential polyuria a functional anomaly of the renal parenchyma, in virtue of which a normal concentration of urine cannot be effected.

Hydrocele.—Posner gives a brief résumé of the pathology and therapy of this affection, intended evidently for the general practitioner. Symptoms and therapeutic indications are, as he states, well understood. But new minutiæ continually come to light and these affect special classes of cases. The author has seen much hydrocele in the elderly, although the disease in textbooks is often considered as one of early and middle manhood. His own experience would make of the affection a companion of prostatic hypertrophy. Such an idea is by no means new—in fact, nearly forty years ago Panas called attention to this association. The question which naturally obtrudes itself concerns the possibility of hydrocele being set up by prostatic catheterization. This appears to be only a detail. Under diagnosis not much is to be added to textbook information. There are some new resources for transillumination, which are hardly necessary to relate. Cytological and chemical examination of the hydrocele fluid is in general well understood, but the author dwells much on the special information afforded by the polarization-microscope. The demonstration in the fluid of spermatocytes, cholesterin, and lipoids in general still belongs to the speculative domain and will hardly possess any significance for the general practitioner. In regard to the treatment, most surgeons wish to do a radical operation in preference to the use of irritating injections. Many patients refuse a radical intervention, and a palliative puncture should not be despised in such cases.

Münchener medizinische Wochenschrift.

February 28, 1911.

Salvarsan in Ulcerous Stomatitides.—Gerber believes that a large number of ulcerous affections of the mouth, gums, throat, etc., may be directly dependent on buccal spirochetes. The latter may be ordinary saprophytes which become pathogenic only when some severe constitutional affection is present, or they may themselves have special pathogenic powers and act on relatively normal individuals. Much of the author's paper is devoted to the Plaut-Vincent angina, which is ordinarily regarded as a quasispecific infection. But in addition we have to consider the actual cause of the lesions in mercurial stomatitis, scorbutus, noma, etc. Such affections are usually held in check by cleanliness; and when this is not observed the ordinary buccal spirochetes contribute largely to the development of actual lesions. The author, in the interest of simplicity and supported by actual findings, is inclined to believe that the spirochete which helps to cause the Plaut-Vincent angina may be the active factor in mercurial stomatitis, scorbutic gingivitis, and noma, as well as certain unclassified affections. It is true that other factors coexist—for example, the fusiform bacillus in the Plaut-Vincent angina. Many cases are cited which appear to show that salvarsan, as a spirocheticide, is able to control such conditions. The author would inject this remedy in all cases of stomacace, or diseased mouth, on general principles. His experience thus far is limited, but in the cases tested—Plaut-Vincent disease and scurvy—the patients improved rapidly and spirochetes disappeared from the mouth.

General Infection with Gonorrhea.—Leede refers to the vast accumulation of data on this subject during the past twenty years and awards most of the credit for this development to French writers. The irregularities and vagaries of this form of sepsis, or toxemia, seem unlimited. It is very nearly an axiom that chancroid cannot infect the system at large; but as it was shown long ago that chancroid may furnish a port of entry for the syphilitic virus, so it has been shown that in very rare instances a gonococcic infection of the blood may occur through a chancroid. An example of this sort is given in full detail, the patient having been attacked with a polyarthritis. The genital lesions were chancroids only, urethritis being absent. The author is his own most strict

critic. He does not look upon the case as a sepsis, but rather as a toxemia. There is indeed a gonococcus-sepsis which may prove fatal by setting up endocarditis. But there is also a gonotoxemia which causes trophoneurotic changes, these including amyotrophy, fatty heart, and a general cachectic condition.

Origin of Menstruation.—Theilhaber states that menstruation cannot occur without a high degree of uterine hyperemia. Of late years he has recorded the date of menstruation in connection with operations on the genitals. The psychogenous element may thus be brought out and is found to be variable. It often appears immediately after some operative intervention on the adnexa of the uterus. The menses may be anticipated by a very variable interval. Apparently it is not precipitated in advance of an operation. Next is the psychogenous element, which can only precipitate a menstruation. We must consider the oöphorogenous factor. The author is a sceptic in regard to the latter. If an ovum is impregnated a marked hyperemia of the genital canal may ensue, which increases with the size of the ovum. When this is expelled the hyperemia vanishes.

Deutsche medizinische Wochenschrift.

March 2, 1911.

Mechanism of the Tuberculin Reaction.—Kraus and two others working in Paltauf's laboratory decide that the tuberculin reaction cannot be due to anaphylaxis because no reaction substances can be found in the blood, and the phenomena produced in no way resemble anaphylaxis. The cachexia reaction in the tuberculous is like other cachexia reactions and is due in all probability to a subsensitiveness of the skin to toxic substances and therefore not specific. Tuberculin is not a typical toxin, for it does not produce an antitoxin in the healthy. It is, however, true that in the tuberculous antibodies are produced with old tuberculin, due to the action of the latter on the skin, and known as anticutins. There is evidence that further antibodies may be thus produced, so that the tuberculin reaction becomes intelligible.

On the Part Played by Tuberculosis in Causing Intraocular Hemorrhage, Retinal Proliferation, etc.—Axenfeld and Stock refer to the obscure intraocular hemorrhages in young people, and the so-called retinitis proliferans, conditions which they now believe to be—in part at least—results of tuberculosis. In other words, they are paratuberculous lesions. We know that in the tuberculous more or less transitory perivascular lesions may develop in the retina, the type of which is a periphlebitis. The lesions occur as small, circumscribed foci, without much inflammatory reaction. They may coexist with tuberculosis of the uvea or elsewhere in the eye. There is considerable doubt as to whether bacilli are present in the lesions, which appears to be due rather to the toxins.

Ankylostomiasis.—Bruns refers to the twofold character of this worm disease for the German sanitarian. The *A. hominis* or *duodenale* has been known in Europe since 1838. On the contrary, the *A. Americanum* or *necator* was first discovered in the United States by Stiles in 1902, and has remained unknown in Europe until quite recently, having been imported by returning Italians and other Europeans. As the *A. duodenale* was naturally carried to America, the two parasites may now be said to exist side by side in both countries. While structural differences exist, the two parasites agree closely as to endemiology, so much so that they may almost be regarded as one. But certain differences still obtain, for in Germany ankylostomiasis is nowhere a universal plague, but occurs in select localities only. In the southern United States the disease is much more evenly distributed. Moreover, since 1903 sanitary precautions in Germany have reduced the incidence of the disease enormously. In that year over 14,000 victims were known. A sanitary crusade cut down the morbidity to an almost vanishing point, as judged by the test of stool examinations. Yet the residue has not been eradicated. The coal miners still exhibit a certain percentage of "carriers," even if the results of the parasitism are no longer in evidence. Treatment of carriers by vermicides of all kinds is not wholly successful despite the fact that 40,000 cures by male fern are on record. Reports from the United States show that the necator is not especially vulnerable to the fern. Future research will doubtless show why the disease cannot be completely eradicated.

Potassium Permanganate Poisoning.—Cohn writes a brief monograph on this subject, giving a bibliography. He refers to the recorded cases and gives one of his own in detail. The condition is very rare, and the first to be recorded was held to be unique because the drug has been freely employed in medicine in desperate diseases and also used as an abortifacient in large dosage. Its local use is very extensive, yet absorption phenomena are hardly known. Nevertheless, in recent years cases of poisoning have multiplied because it is possible to ingest the drug in large quantities either by error or in suicidal attempts. Just why the public should look upon the drug as lethal in large amounts does not appear, as it is not considered under toxicology. Of the recorded cases of poisoning some ended fatally, others like the author's in recovery. That the drug should have toxic powers is not surprising, for both potassium and manganese exert well-known toxic effects. But neither this argument nor any other can fully explain the recorded cases. We know that the drug is a local irritant and when swallowed irritates the gastric mucosa. This would readily be explained through its property of liberating oxygen when in contact with organic matter, since most oxidizing substances are local irritants. The author, analyzing the toxic effects, finds first of all a local corrosive action. But this does not account for all the clinical picture. The drug can evidently enter the circulation, depress the heart, and irritate the kidneys, which presumably eliminate it. Death may occur from indirect causes, as aspiration-pneumonia. The inference is that the drug should be placed among the poisons.

Pathology of the Thymus.—A. B. Marfan gives an excellent account of the pathological conditions of the thymus. Atrophy is rare; hyperplasia resulting in hypertrophy is more frequent. The function of the gland is at its highest point just before and after birth, and pathological symptoms occur for the most part during the first two years of life. Hypertrophy is observed in all the acute infections, in myxedama, Graves' disease, acromegaly, tetanus, etc. The chronic infections, syphilis and tuberculosis, cause hypertrophy of the gland. The author believes that by percussion we may determine the size and location of the gland, and radioscopy and radiography confirm the pictures. Tracheoscopy shows a trachea flattened by the enlarged gland. The chief symptom resulting from hypertrophy of the thymus is dyspnea, especially in inspiration. This may be chronic without attacks of extreme dyspnea and cyanosis; it may be chronic with periodic attacks of dyspnea, spaced by periods of normal breathing, and it may come on suddenly with a fatal result in a few minutes. Sudden death under anesthesia is referred to hypertrophy of the thymus, and some cases of asphyxia in the newborn result from pressure of the enlarged gland. Treatment of this condition consists in the application of radiotherapy in chronic cases, or surgical removal of the whole or a part of the gland; or palliation may be obtained by the introduction of a long tube in the severe attacks of dyspnea.—*Archives de Médecine des Enfants.*

Book Reviews.

Gedanken zu einer Universalpathologie. Von Dr. med. vet. et phil. Friedrich Freytag, Privatdozent an der Universitat Bern. Berlin: Verlag von O. Haring, 1910.

The writer disarms criticism on his first page by stating that these thoughts concerning general pathology may not be as new as they seem. This is no great comfort, for it is questionable if they should have appeared in print at all, whether new or old. The pamphlet is largely an unscientific criticism of bacteriological and serological problems, the writer's animosity being chiefly directed against prophylactic and therapeutic inoculations in one of the types of swine plague.

The Treatment of Disease. A Manual of Practical Medicine. By Reynold Webb Wilcox, M.A., M.D., LL.D., Professor of Medicine (Retired) at the New York Post-Graduate Medical School and Hospital; Consulting Physician to St. Mark's and to the Nassau Hospital; Formerly President of the American Therapeutic Society. Fellow of the American Academy of Medicine and of the American Association for the Advancement of Science, etc.; Third Edition, thoroughly revised and enlarged. $7.50. Philadelphia: P. Blakiston's Son & Co., 1911.

That this work has gone through two editions in not much longer than three years is a sufficient evidence of its popularity. Moreover, it is fully deserving of the hold that it has gained on the medical profession for several satisfactory reasons. Despite its title, which might lead one to suppose that it deals wholly with treatment, it really discusses the entire practice of medicine, together with its allied branches. The reasons, however, that the work has had so favorable a reception are probably to be found in the fact that the greater part of the volume is given over to prophylaxis and treatment of disease and that these subjects are regarded from an optimistic standpoint. Therapeutic pessimism has been preached with much success both in Europe and in this country, and it is good for all concerned that the reverse of the shield should be ably exhibited. Dr. Wilcox is an eloquent exponent of the virtues of curative and remedial therapeutic treatment. This third edition has been revised and forty-three sections, devoted to as many diseases, have been added. It is interesting to note that the author is not in favor of the cold bath treatment of enteric fever, a treatment that has a considerable vogue in America. In the treatment of syphilis the various forms of mercurial administration and application are mentioned, but no reference is made to the employment of the arsenical combinations. The book is an excellent summary of our present-day knowledge of the rational therapeutic treatment of disease, treatment for the most part founded on the experience gained by medical practitioners during a considerable period. As a reliable work of reference it may be heartily recommended.

Diagnosis and Treatment of Diseases of Women. By Harry Sturgeon Crossen, M.D., Professor of Clinical Gynecology, Washington University; Gynecologist to Washington University Hospital and Director of the Gynecological Clinic; Gynecologist to St. Louis Mullanphy Hospital, to Missouri Baptist Sanitarium, to Bethesda Hospital, and to the St. Louis City Hospitals; formerly Superintendent of the St. Louis Female Hospital; Fellow of the American Gynecological Society, of the American Association of Obstetricians and Gynecologists, and of the Western Surgical and Gynecological Association; ex-President of the St. Louis Obstetrical and Gynecological Society; Member of the American Medical Association, Missouri State Medical Association, St. Louis Medical Society, etc. Second Edition, Revised and Enlarged. With 744 Engravings. St. Louis: C. V. Mosby Company, 1910.

This book deals with the diagnosis and treatment of the diseases of women, as seen by the general practitioner in the office and at the bedside. In the first chapter the various examination methods are fully described, each step being very clearly illustrated by drawings and photographs. In the second chapter the symptoms of gynecological diseases are considered, as well as the differential diagnosis of the various abdominal and pelvic conditions. The third chapter deals with the various general and special therapeutic measures applicable to gynecological treatment. The indications for their use are clearly stated. These three chapters are very important parts of the book, and if they are thoroughly understood by the student they will furnish him with an excellent knowledge of the essentials of gynecological diagnosis and treatment. In the chapter devoted to the diagnosis of malignant diseases of the uterus the author has very wisely confined himself almost entirely to the consideration of diagnosis of carcinoma and sarcoma in the early stages. Too much stress cannot be laid on the early diagnosis of malignant diseases, for only in the early stage can we operate with the possibility of effecting a cure. Dr. Crossen favors the abdominal route in operating for cancer of the cervix, but he has no serious objection to the vaginal operation if it includes the technique required for the removal of the parametrium. As he considers the operation elaborated by Wertheim one of the best of the radical operations, he has described it in full. Special attention has been given to the consideration of pelvic inflammation and extrauterine pregnancy. In a chapter entitled "Disturbances of Function" are considered amenorrhea, menorrhagia, dysmenorrhea, and leucorrhea. We are glad to see that the author recommends the Dudley operation in those cases of dysmenorrhea, due to anteflexion of the cervix, which are not relieved by a thorough dilatation and curettment under anesthesia. There are short chapters on the "After-Treatment in Operative Cases" and "Medicolegal Points in Gynecology." The illustrations, of which nearly 300 are original, are excellent. The book presents the subject of gynecology in a clear, concise, and readable manner, and will be of service to both the student and the general practitioner.

A Text-Book of Veterinary Anatomy. By Septimus Sisson, S.B., V.S. Professor of Comparative Anatomy in Ohio State University, Columbus, Ohio. Member of the American Association of Anatomists. With 588 Illustrations. Many in Colors. Philadelphia and London: W. B. Saunders Company. 1910.

This book cannot fail to be welcomed by all who are interested in the science of comparative anatomy, for the want of such a work in the English language is one of long standing. Here is a treatise that ranks with the best works on human anatomy. The treatment of the subject-matter is eminently scientific and embraces the exhaustive gross anatomy of the principal domestic animals—the horse, ox, pig, and dog. To the chapter on splanchnology is added a section describing the digestive system of the sheep. Modern methods have essentially altered the long accepted opinions concerning the normal form of many of the viscera and have opened the way to far greater accuracy of statement in the field of topography. As improved methods have revealed numerous errors in prevailing opinions concerning the human viscera, so the author, availing himself of the most modern laboratory equipment, has detected and corrected equally grave errors relating to the viscera of the domestic animals. Embryological and histological data are not considered, as it was designed to have the text-book of convenient size for reference. English nomenclature in the science of veterinary anatomy is chaotic, and the author in consequence has eliminated certain useless and erroneous terms, often adopting the original Latin or anglicized form of those selected by the Congresses at Baden and Stuttgart. Although in sympathy with this improved terminology, he favors for the present a stage somewhat transitional and sometimes adds these terms in parentheses. The Anatomy consists of 826 pages, including an elaborate index which greatly enhances the value. The author is to be congratulated on his appreciation of this part of the work, so commonly neglected to the great detriment of any book. The fine illustrations, many in colors, offer another valuable and attractive feature. Besides the numerous original illustrations, are others taken from the works of Ellenberger and Baum and Schmaltz. It is pleasant to review such a comprehensive and scholarly treatise, marking as it does a distinct advance in the English literature on this subject. The book deserves a place in every medical library, whether public or private.

Uric Acid in the Clinic. A Clinical Appendix to "Uric Acid as a Factor in the Causation of Disease." By Alexander Haig, M.A., M.D., Oxon., F.R.C.P. Senior Physician to the Metropolitan Hospital and the Royal Hospital for Children and Women; late Casualty Physician to St. Bartholomew's Hospital. Assisted by Kenneth G. Haig, L.R.C.P. Lond. M.R.C.S. Eng. Philadelphia: P. Blakiston's Son & Co, 1910.

This work of some 300 pages is a summary of cases illustrating Dr. Haig's well-known theory that uric acid is a most important, if not the most important, factor in the causation of disease, and that the only salvation of mankind, from the health point of view, is to refrain from eating such foods as tend to produce uric acid to excess in the human system.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held February 16, 1911.

The President, Dr. William M. Polk, in the Chair.

Skiagraphy in the Surgery of the Bones and Joints.—Dr. Fred H. Albee read this paper. He stated that the intelligent interpretation of the skiagraph required on the part of the observer an intimate knowledge of the radiographic art, as well as a close acquaintance with the normal and pathological skiagraphic appearances of bones and joints. A knowledge of the development of the normal skeleton was also of the greatest importance The writer had seen men otherwise very competent mistake normal epiphyseal cartilage for a fracture and later boast of the excellent functional result which his treatment had secured; he had seen radiograms of the wrist and foot criticised because they did not show a Colles' or a Pott's fracture when very distinct fractures of the carpal or tarsal bones were present; he had seen a normal sacroiliac joint diagnosed tubercular from the radiographic findings alone, because a bubble of gas in the intestine happened to become superimposed in this region; he had seen a case of myositis ossificans of the thigh diagnosed as periosteal sarcoma from very excellent skiagrams and an immediate hip-joint amputation advised without microscopical examination. However, these mistakes could be more readily excused than overconfidence in one's diagnostic powers which refused to ask for the aid of fluoroscope or skiagram. A skiagram often gave unexpected aid in clearing up an obscure diagnosis. Tuberculosis was the most common bone disease and was thought by many pathologists to be nearly always primary in the bone, but this belief was not confirmed in a large percentage of cases by the skiagraphic findings. Although it was not unusual to find a distinct bone focus, it was more common to discover first the thickened capsule with a blurring of the outlines of the bony elements of the joints, later the erosion of the articular surfaces, and finally a real destruction of bone. A very strong evidence of bone tuberculosis, which was often earlier than any of the above features, was bone atrophy, not only locally but in the neighboring bones. This change could often be detected even before atrophy of the soft parts took place. As the atrophy advanced in the osseous type destruction was the most characteristic feature shown in the negative. The bone broke down, small sequestra formed, subluxations occurred, and detritus was thrown out with or without circumscribed abscess formation. Finally, bony repair began to take place and the most marked feature of the advent of this change was the return of the normal sharp outline of the bony elements of the joint with new bone formation and ankylosis, or else practically a new joint might form with more or less motion, usually less. Three types of skiagrams of as many varieties of this disease might he described: 1. The skiagram was negative except for the blurring of the outlines and diffuse atrophy of the highest grade. 2. Atrophy of more varying grade, blurring of outlines, and irregular mottling of cancellous bone tissue were found. 3. A less amount of atrophy was seen, but at some particular point of the bone shadow a circumscribed spot was found with an irregular and indented border. Tuberculosis in bone was healed by changes having their greatest activity in the periphery of the lesion. In view of these findings it would be appreciated that much could be discovered as to the progress of the disease by a repetition of exposures at intervals. These skiagraphic warnings occurred many times before the advent of disquieting clinical symptoms. Tuberculosis of the phalanges was frequently confused with a similar syphilitic affection and the skiagraph was of extreme importance in making a diagnosis. In the tuberculous variety there was marked atrophy of neighboring bones, a cyst-like condition of the phalanx, usually beginning in the spongy ends of the bones and associated with involvement of neighboring joints. In syphilis there was less atrophy and the articular surfaces were less often involved. There was a new deposit of bone beneath the periosteum and the old line of cortex could usually be seen. If loss of substance occurred the bone ulcer would present clear-cut edged and punched out appearance. The tuberculous variety was much the commoner. In contrasting osteomyelitis with tuberculosis the writer stated that while the latter most commonly affected the epiphyses and articular surfaces, the former rarely did so. An important feature was the absence of bone atrophy which was so constant an accompaniment of tuberculosis. There were to be seen, especially in the more chronic cases of osteomyelitis, an actual cortical thickening and a ring of bone about the osteomyelitic cavity which was more resistant to the passage of the *x*-ray than the rest of the shaft. The sequestra found were often large and of considerable *x*-ray density. Dr. Albee considered only a few of the numerous bone and joint lesions that resulted from syphilis. The early forms of hereditary syphilis resembled rickets. A late form of hereditary syphilis, a juxtaepiphyseal lesion, deserved special mention. This type manifested itself as a marked tumefaction in the region of the epiphysis. Microscopically these swellings were osteochondromata, which gave a peculiar mottled *x*-ray appearance due to islands of bone in a matrix of cartilage. Thickening of the cortex and the periosteum were the most characteristic evidence of both hereditary and congenital syphilis. The thickening of the cortex was often so marked on one side of a long bone as to cause it to bend, giving rise to the so-called saber-shaped bone. Along the periphery of this thickened bone small areas of rarefaction frequently appeared with a dense shell of bone over them; these had been called bone blisters by Codman and were usually due to a secondary pyogenic infection. Many distinguishing characteristics of sarcomata could be discovered by the skiagram. The myelogenous variety was usually found at the rapidly growing ends of long bones and was very prone to cystic formation. The spindle celled periosteal type presented itself in the form of dense swellings with a typical radiating and infiltrating appearance from the superficial part of the bone. This type more often involved the middle of the shaft and was the most malignant. The skiagram was most trustworthy in the differential diagnosis of coxa vara, hip disease, congenital dislocation, and extra articular disease. Solitary bone cysts frequently occurred near the end of the diaphysis of long bones and spontaneous fracture sometimes occurred through one or more of these cysts; in such an event a skiagraphic diagnosis was absolute. The writer also pointed out the great value of the *x*-ray in the congenital dislocation of the hip and its use in the treatment of this condition by an exposure after the operation through the plaster-of-Paris spica.

The Value of Radiographic Examination in the Early Diagnosis of Carcinoma of the Stomach, also Gall-Bladder Infections, Shown by Adhesions Around the Pylorus.—Dr. Lewis Gregory Cole read this paper, which he illustrated with lantern slides and cinematographic demonstration of gastric peristalsis. The apparatus which he used had been fully described in his paper read before the last meeting of the American Roentgen Ray Society. In order that one might recognize in the radiograms the presence of carcinoma, infiltrated ulcer, and adhesions around the pylorus, one must first be familiar with the various types of peristaltic contractions in the stomach where these conditions were absent. He first

exhibited slides showing the different types of stomach, the sternenhorn, the text-book type, the vertical or fish-hook, the drain-trap, the dilated, the dilated with prolapsed pylorus, a stomach with rugæ visible on the anterior wall. All these types had been recognized and used in diagnosis for three or four years. He next demonstrated peristalsis in the normal stomach. Holzknecht had examined thousands of cases fluoroscopically and gave the fluoroscopic appearance of the motor phenomena of digestion as follows: "While there was no active movement to be seen in the cardiac end of the stomach the lower portion of the greater curvature exhibits deep contraction. These depressions travel toward the pylorus, gradually getting deeper during their passage, till they get their maximum depth at the sphincter pylori, a point three or four finger breadths above the pylorus. The maximal point of depression is characterized by the length of time it remains in a state of tonic contraction, and by the fact that the contractions here are the most energetic of any part of the stomach wall. Opposite to this deep constriction of the greater curvature appears a similar depression of the lesser curvature visible in the upper part of its contour. Eventually the depression of the smaller and that of the larger meet, so that on the screen there is seen a clear line between the shadow of the contents of the corpus and of the antrum. Soon afterward the shadow of the antrum disappears, its contents being emptied into the duodenum by a process of concentric contraction." The next plates illustrated the type of stomach described by Kaestle, Rieder and Rosenthal, which they claimed exhibited normal motor phenomena with two antra. From a study of the best plates which he had obtained in this investigation he concluded that there were four or more contractions in the majority of stomachs where peristalsis was reasonably active. In these might be seen a well defined antrum, a preantrum, and two or more distinct contractions which extended even up to the cardia. Sometimes five, six, seven or even eight contractions were seen in a stomach functionating normally as was demonstrated by plates. A different motor phenomenon had been observed from those previously described; namely, a systole and diastole of the stomach which appeared to correspond with inspiration and expiration. In a number of slides showing pathological conditions there seemed to be almost no attempt at contraction. Braunig suggested a relation between the production of hydrochloric acid and the peristalsis, and Dr. Cole's experiences tended to confirm this theory because the glands which secreted this acid were at the pyloric end of the stomach and any condition which affected the peristalsis would likewise affect the activity of these glands. It was possible that certain types of indigestion might be due to the absence of peristalsis caused by malposition or adhesions. These two fields were suggested as offering great opportunities for research work. Plates were shown demonstrating the effect on the peristalsis wave made by adhesions, infiltrations, and carcinoma. The effect of an infiltrated or carcinomatous area in the wall of the stomach was best illustrated by a partially inflated automobile tube. When this was passed through the hands a crease remained at the bottom, slipping along smoothly. If a patch was put on the tube, the crease would jump it instead of passing through. This was precisely what occurred in areas of infiltration of the stomach or where there were adhesions binding it to adjacent viscera. During this investigation, adhesions around the pylorus resulting from gall-bladder disease occurred so frequently that it seemed probable that this method of detecting gall-bladder infections might open up a new and definite field for radiography. It was well known that adhesions occurred in a very large percentage of gall-bladder infections. A series of slides and cinematographic films of the pylorus and duodenum, both in cases where there had been a definite history of gall-bladder infection, and where gall-bladder disease had been verified by operation were shown. A study of these later led him to believe that gall-bladder conditions might be differentiated in radiographic examination.

Dr. G. E. Pfahler of Philadelphia, in discussing Dr. Cole's paper, said that everyone who had seen the beautiful demonstration and listened to the interesting paper felt deeply indebted to Dr. Cole for his untiring efforts in developing the cinematographic process for the study of the stomach which had been begun so ably by Prof. Rieder and Drs. Kaestle and Rosenthal of Munich two years ago. Dr. Pfahler demonstrated the film made by these gentlemen. The work required much time, energy, and expense and these workers, therefore, deserved much credit. This was unquestionably the best method of demonstrating to an audience the peristaltic waves of the stomach. As a means of diagnosis he thought that it didn't compare with careful fluoroscopic work, for fluoroscopically one could study not only a wave passing but many waves and this could be studied with varying degrees of filling, under the influence of respiratory movement, and as affected by palpation. The speaker criticised Dr. Cole's technique because he believed that one could never get a true record of the position of the stomach when the patient was lying upon the abdomen, since this outline was influenced too much by the amount of pressure, by the quantity of abdominal contents, and because it did not give the stomach hanging from its support, namely, the cardiac and the duodenal attachments. For the same reason his position did not serve so well to demonstrate the effects of adhesions. These examinations should generally be made in the upright position. As a rule he made his studies both fluoroscopically and radiographically in the upright position. He had selected lantern slides from about twenty-five cases which had shown gastric and duodenal adhesions in the neighborhood of the gall bladder which he demonstrated. Most of them had been confirmed by operation or autopsy. Some were due to malignant disease, some to tuberculous peritonitis, and some to cholecystitis. The peristaltic wave was usually interfered with by these adhesions, but not always, and the stomach was apt to be drawn upward and to the right. He believed that the Roentgen ray was unquestionably the best means at their command for demonstrating the effects of such adhesions preliminary to operation.

Stated Meeting, Held March 2, 1911.

The President, Dr. William M. Polk, in the Chair.

Physiology of Salvarsan.—Dr. S. J. Meltzer read this paper. (See page 515.)

Clinical Results from the Use of Salvarsan.—Dr. Howard Fox and Dr. Wm. B. Trimble presented this paper. They stated that no new remedy had ever been given such an extensive preliminary trial in hospitals before being put upon the market. In all fairness to Ehrlich's preparation it must be said that most of the numerous communications upon the subject dealt with the result of a single injection. It was not impossible that repeated doses with new or combined methods of technique might add to the efficiency of the remedy. Every observer who had had a moderate experience with salvarsan must admit that in certain cases at least the new remedy had a powerful action in causing the disappearance of syphilitic manifestations. This symptomatic action was often strikingly shown in lesions of the mucous membranes, mucous patches, for instance, disappearing at times in from twelve to twenty-four hours. Since the drug furthermore caused a rapid covering of the chancre with epithelium, its employment would prove of great value where it was desired to lessen as quickly as possible the danger of infecting

others. Its action in causing the disappearance of the induration in the chancre and lymphatic glands was slow and unsatisfactory. The effect of salvarsan upon early cutaneous syphilides was only moderately rapid. In the case of the large, flat papular syphilides it was generally admitted to be slow, a fact which coincided with their observations. Its effect upon the macular and upon the small flat and miliary papular syphilides was generally conceded to be somewhat quicker. In these forms of cutaneous syphilis the results of its action could not be called very brilliant. In the later cutaneous manifestations they had seen some excellent results comparable to those which had been reported by many other observers. It was in the malignant precocious type of the disease that the most brilliant results had been obtained. Salvarsan had also shown its value in severe cases of syphilis that had proved refractory to mercury. Its action was furthermore of value in those few cases in which mercury could not be tolerated. Good results had been reported in congenital syphilis and satisfactory results had been obtained in the treatment of active syphilis of the nervous system, while in parasyphilitic affections such as tabes and paresis its effects had been found to be of little or no value. Fordyce had treated eighteen cases of tabes and considered the results discouraging. The action of salvarsan on the *Spirochæta pallida* had been found by a large number of observers to be very energetic. In the majority of the cases the organisms disappeared from the various lesions in from twelve to twenty-four hours. The question of the permanence of the action of this remedy was difficult to answer. The number of relapses that were being reported was increasing as time elapsed and had largely destroyed the hope that syphilis might be cured by a single injection. A letter recently sent out by the *Medizinische Klinik* requesting information upon the number of relapses that were being obtained, elicited the information that from a combined material of 4,766 cases only 207 relapses had occurred. Judging from their experience Dr. Fox thought this number appeared to be rather too low. They felt confident that as time went on a much larger number of relapses would have to be recorded. In order to obtain a true idea as to the permanent action of salvarsan it would be necessary to carefully follow the cases for a number of years. It was undoubtedly true that in many cases treated by salvarsan equally good, if not better, results could have been obtained by mercury. In lesions of the mucous membrane the action of salvarsan was more rapid than that of mercury. They did not agree with Fisher that the new remedy should be reserved solely for cases that were refractory to mercury. Relapses seemed to occur more frequently after treatment with salvarsan than after treatment with mercury. Except in certain selected cases they did not think that salvarsan would replace the use of mercury. The undesirable effects of the injection varied according to the method employed. The subcutaneous injections of a neutral suspension had been practically given up owing to the possibility of necrosis. The effects of an intramuscular injection of an alkaline solution was at times very painful. The local effects of an oily suspension given in the buttocks was usually well borne, especially when the injection was followed immediately by vigorous massage. A properly given intravenous injection should not be followed by any unpleasant local disturbance. The disagreeable effects of this remedy had been generally in their experience transitory and of little importance. According to their present knowledge the most efficacious form of administration appeared to be an intravenous injection followed in four days or later by an intramuscular injection of an oily suspension.

Technique of Intravenous Injection of Salvarsan.—Dr. Homer F. Swift demonstrated the preparation of the salvarsan solution and how it should be employed.

Observations on the Wassermann Reaction after Salvarsan.—Dr. Homer F. Swift read this paper. He said that the change in a reaction might be due to non-specific alteration in the blood serum, such as an increase in the hemolytic power of the serum as certain observers had claimed to have found with mercury. Schwartz and Flemming found in their test tube experiments that salvarsan had no power to alter either a positive or a negative reacting serum when it was added to the serum in dilutions much higher than one would have after an intravenous injection. It had practically no hemolytic power, so any effect on a positive reaction was due to a reduction in the amount of antibodies. This reduction might be absolute or relative. The absolute would indicate a fairly complete sterilization of the body, or that a few remaining spirocheta were so encapsulated that at some time they did not give rise to any antibodies in the blood serum. The relative reduction was probably due to a decrease in the number of active spirochetes and the detection of this decrease was dependent upon the sensitiveness of the test applied. The quantitative methods of performing the reaction would no doubt show a greater number of changes than the single tube method, but the latter gave a good idea of the negative and positive phase. With sensitive antigens and well controlled tests any serum which showed a moderate inhibition as compared to a negative serum could be considered positive in so far as prognosis was concerned. The writer reviewed the work of a number of observers and concluded that the difference in results only showed how difficult it was to make any definite rules as to the effect of the drug on the reaction. A chart was presented showing the reaction in 42 cases which had been followed for a length of time sufficient to see some effect. Of this number 16 had intramuscular, 24 intravenous, of whom 13 had two injections and 2 had combined injections. The intramuscular cases had all been followed for three months or more. Four of them had not reported in the past six weeks, but up to the present 7 of the 16 had remained negative. Four more which were negative had become positive; one was weaker and two were unchanged. Of the 24 intravenous cases, which had become and remained negative or much weaker, seven which became negative or much weaker were now growing stronger and seven had been unaffected. The two combined intravenous and intramuscular injections were in children with congenital syphilis who had shown marked clinical improvement, but no permanent effect on the reaction. The chart showed a decided advantage on the side of the intramuscular method, but it did not indicate the difference in the rapidity of action with the two methods. A change in the intensity of reaction was much more quickly noted after the intravenous method, and in those cases in which the reactions had relapsed the return was also more rapid. This difference in the length of the positive and negative phase was no doubt due to the more rapid elimination of the drug after the intravenous method. It seemed probable that one could determine the total effect of the treatment sooner after the intravenous method. The best total effect could be obtained from a combination of the two methods. The wonderful effect of salvarsan on the clinical manifestations of lues and the marked influence in causing spirochetes to disappear when they could be demonstrated before treatment, placed the Wassermann reaction alone as the best evidence as to the ultimate effect of the drug. Were it not for the Wassermann reaction many more treated cases would be regarded as cured and the persistence in treatment which was so necessary for a final and permanent cure could not be carried out with such a degree of certainty. Therefore the Wassermann reaction had become the most important guide in following the effect of the drug on the individual case.

Ehrlich-Hata's Arsenobenzol and Serum Diagnosis

of Syphilis.—Dr. H. Noguchi presented this paper. He reviewed the literature with special reference to the number of relapses and the effect of the treatment upon the Wassermann reaction. Lange, who analyzed Wechselmann's cases, found that 153 out of 268 cases became negative in five weeks after injection. The reaction was still positive in 97 cases when examined at the end of five weeks, although a certain reduction in the strength of the reaction was noted in 34 of these cases. According to Michaelis the serum reaction might become negative within a period of from two to ten weeks after injection. In a few instances the reaction became stronger than before the injection. Treupel, Halbertstaedter, Ledermann, Schlesinger, Bruhns and Hoffmann experienced very slow reduction or persistence of the reaction in most of their patients. On the other hand, Kromayer, Gennerich, Linser, Cramer and others saw the reaction disappear, in at least 50 per cent. of the cases, within four or five weeks. In this work the arsenobenzol was used either in a neutral or a slightly alkaline suspension and administered intramuscularly by one set of investigators and subcutaneously by the other set of investigators. The earlier cases received only 0.3 gram as a dose instead of 0.6 as recommended later. In reviewing the entire literature on the subject Dr. Noguchi found that the statements in regard to the Wassermann reaction were extremely brief and vague. He had undertaken with Bronfenbrenner a series of examinations of cases treated with arsenobenzol. The total number of cases available for complete serological analysis was 102. More than one-half of these had been under observation for a period of three months, while the latest cases were injected about four weeks ago. The amounts of the arsenobenzol used were 0.5 to 0.6 for men, 0.4 to 0.5 for women and 0.015 to 0.025 for children. The modes of injection were variable. From his experience he considered the intravenous injection of an alkaline solution best and the subcutaneous administration worst. The quantitative determination of the serum reaction in each case was carried out by the author's method, the blood being examined before the injection, and then one day, three days, one week, after the injection and afterwards once weekly. Examining the varieties of the reactions in the 102 strongly positive specimens it would be noted that in primary, secondary, tertiary, and hereditary syphilis the average specimens contained more than one antibody unit, frequently two, three, and four units. In one specimen as high as ten units was encountered. After the injection none of the specimens contained more than four units. In reality the positive specimens contained usually only one or two units. The reaction was lost in 30 cases, reduced to less than one antibody unit in 24 cases, while the remaining 48 cases still contained more than one antibody unit and gave strong positive reactions. These cases, while still retaining strong positive reactions, were decidedly reduced in antibody content. The average antibody units for primary cases was only 1/5, that for secondary cases 2/7, that for tertiary cases 5/18, that for latent cases ¼, that for hereditary cases 10/27, that for cerebrospinal cases 2/3, and that for tabes ¼ of the original antibody contents. This showed that the arsenobenzol had the effect of reducing the antibody content in general. Considering the frequency with which positive reactions became negative after treatment they found that in 40 per cent. of the primary cases, in 37 per cent. of secondary, in 35 per cent. of tertiary, in 33 per cent. of latent, in 14 per cent. of hereditary and in 50 per cent. of incipient tabes the reaction was lost. All cases of cerebrospinal syphilis became somewhat weaker, but remained positive. The average of the negative reactions corresponded to 33.7 per cent. of the total 102 cases. The percentage of weak positive cases was 19.8 of the total, but this group of cases was progressively losing the strength of the reaction and was likely to fall in due course of time into the negative group. The writer next considered the relation between the clinical and serological findings. In 66 cases which responded favorably to the arsenobenzol and lost the clinical symptoms within a few weeks the serum reaction became negative or reduced in strength. The effect of the treatment was far more prompt upon the clinical symptoms than upon the reaction. In a large number of cases symptoms began to clear up within a week, not infrequently within twenty-four hours after the injection. The reaction became weaker very gradually. In promptly cured cases the reaction might disappear within two weeks, although in some instances it might take four or five weeks. Data were also presented in regard to the time of disappearance of the reaction in cases of different stages of syphilis after the injection of the arsenobenzol. In 20 cases where clinical improvement was very slow the reaction was also extremely slow in diminution and in some cases it became stationary. In two cases of tertiary syphilis the clinical symptoms showed but little improvement, while the reaction became slowly but progressively weaker within two months. Six cases of cerebrospinal syphilis showed no improvement clinically, but the reactions were more or less weakened within five weeks. Ten relapses were observed in 102 cases. Most of these were malignant or tertiary syphilis. The recurrence of the disease could always be detected by the return of the reactions which were diminishing until the relapse. Six relapses were reinjected with good results, while one had a second relapse. Among 102 cases there were three cases which showed no effect upon the reaction as well as upon the symptoms. In four instances the reactions became somewhat stronger during a few days following the injection, but their strength was gradually reduced later.

The Present Status of Salvarsan in Syphilis Therapy.—Dr. J. A. Fordyce said during the past year sufficient clinical and experimental evidence had accumulated to attest to the specific action of salvarsan. Many continental observers were of the opinion that if treatment could be given in the primary stage before glandular involvement and a positive Wassermann reaction, one injection would suffice to abort the disease. For the past two months, whenever feasible, the speaker had repeated the injection at the end of from one to four weeks, and where not practicable to do this had advised active mercurial treatment if the serum reaction at the end of a month remained unchanged. Mercury in no way interfered with the action of 606. Of the cases treated in the early secondary stage of the disease two had shown a relapse. Of about 80 cases treated for various types of cutaneous and mucous membrane lesions, in the later secondary and tertiary stages, he had met with four recurrences. These were a case of malignant syphilis, one of condylomata and mucous patches in an alcoholic; a third case with scaling palmar syphilides, and a fourth with plantar syphilides. In the case of malignant syphilis the recurrence yielded to a second injection and the patient who before treatment was extremely cachectic and weighed only 105 pounds now weighed 140 pounds and had been able to resume his work. The patient with the palmar syphilide relapsed five months after the first injection. He was given a second one and had now no clinical evidence of the disease although his serum reaction was still strongly positive. Scaling syphilides of the palm and sole which were notoriously rebellious to ordinary treatment were remarkably amenable to 606, and although he had noted recurrences they had not been as extensive as after mercury. Dr. Fordyce said the striking effect of the remedy on the various cutaneous and mucous membrane manifestations of syphilis could not be gainsaid. The lesions receded quicker than under mercury and the immediate results were superior to those obtained with that drug. From the administration of the drug in about

35 cases of tabes he had been able to draw some rather definite conclusions as to the indications for its use in this condition. Cases of tabes might be divided into two groups, viz., those of years' standing, vigorously treated with mercury and potassium iodide, whose Wassermann reaction was slightly positive or negative and whose cerebrospinal fluid contained no increase or a very slight one of lymphocytes. In these the administration of salvarsan accomplished little or nothing. In the other class with a strongly positive reaction, marked lymphocytosis of the spinal fluid, characteristic pains, with gastric or other crises, and little or no impairment of the gait, the probabilities of relieving the pain or arresting the progress of the disease justified the use of the remedy. In several of these he had noted marked improvement. In tabes, Ehrlich now advised that the drug be given in doses of from 0.1 to 0.2 gm. and repeated several times. Just how often had not yet been determined. Although he distinctly warned against using the drug in advanced degenerative disease of the nervous system, Dr. Fordyce had seen no harm to advanced tabetics to whom doses of from 0.4 to 0.6 gm. had been given. The only unpleasant effect noted had been an increase in the neuralgic pains, which had sometimes persisted for a week or ten days. He had treated one case of paresis in the early stage with decided but transient amelioration of the symptoms. No permanent benefit accrued, as a relapse occurred in a few days. In a case at present under treatment fractional doses of 0.2 gm. and 0.3 gm. had already greatly improved the patient's mental condition and relieved some of his other symptoms. With regard to the treatment of eye affections with 606 several cases of choroiditis with acute optic neuritis coming on in the early stage of the disease had been decidedly benefited. A sharp distinction should be drawn between those cases of acute optic neuritis of undoubted luetic origin and the primary degenerative forms. We had here an analogy between the two types of tabes. In the degenerative forms of the optic nerves and the posterior columns of the cord this drug or intensive mercurial treatment was harmful to the patient, as it probably hastened the degeneration. In the last 60 cases he had treated the intravenous method was used exclusively and he felt that it was the method of choice because of the little inconvenience which it caused in the majority of patients. In a few he had seen a marked reaction within from two to six hours after the injection. This consisted in a chill or chilly sensations, a rise of temperature, and gastrointestinal symptoms. In several cases he had noticed a subnormal temperature, 97°, and in one a slowing of the pulse to 42 within half an hour after the injection. There was less likelihood of a general reaction if the patient took a cathartic the night before and only a very light lunch the day of treatment. He also thought there was less constitutional disturbance since he had substituted distilled water for the saline in making up the salvarsan solution. This was advocated by Schreiber, who believes that too hypertonic a solution is produced by the addition of the physiological salt. As part of the general reaction cutaneous eruptions as herpes of the lips and of the cheek, morbilliform or scarlatiniform rashes, and urticaria were met with. Dr. Fordyce said he was becoming more and more impressed with its marked therapeutic effect, and his belief was being strengthened that we have at last an agent which will materially shorten the period of treatment of syphilis. He had kept in close touch with various patients in all parts of the country and although in some the Wassermann reaction was still positive, they had had no relapse of the clinical manifestations, and wrote in the warmest terms of the benefits derived from the treatment. In conclusion, he added that his faith in the remedy had not abated in the slightest by a more extended observation of its effects. He was, however, more and more imbued with the necessity of the greatest care in its administration, the selection of suitable cases, and the observance of the contraindications definitely laid down by its discoverer. While alarming symptoms might develop in a patient with an idiosyncrasy to arsenic, if used in the proper manner, the remedy seemed to be as free from danger as any of the pharmacologically active drugs.

NATIONAL CONFEDERATION OF STATE MEDICAL EXAMINING AND LICENSING BOARDS.

Twenty-first Annual Convention, Held at Chicago, Ill., February 28, 1911.

The President, Dr. Joseph C. Guernsey, Philadelphia, in the Chair.

An address of welcome was delivered by Dr. George W. Webster, Chicago, which was responded to by Dr. Lee H. Smith, Buffalo.

President Guernsey delivered an address on "Medical Licensure."

Medical Education.—Dr. W. J. Means, Chairman, Columbus, Ohio, presented the report of the committee on the recommendations contained in Mr. Flexner's paper of last year, and stated that they concerned subjects which had been frequently presented and discussed at meetings of the National Confederation as well as of the Association of American Medical Colleges and of the Council on Medical Education. The committee recommended that consideration be given to all of the suggestions made.

State Control of Medical Colleges.—Dr. Charles William Dabney, President University of Cincinnati, said the vital interests of the general public in medical education furnished the strongest argument for the public support and control of medical colleges. The privately controlled colleges had generally lost sight of this, and considered the interests of the profession and of the student the chief thing. In no other way did education as a whole touch the citizen more vitally than in the character of the medical training given in the colleges. The interest of the public in the kind of education given practitioners of medicine was the chief justification of public control of these institutions.

Hon. Charles Alling, Jr., Chicago, spoke of State support and control of medical education, and said that if the courts will sustain as a requirement for an examination a diploma from an institution of the standard raised by the Association of American Medical Colleges they should for the same reason sustain a law providing that the degree of M.D. shall be given only by medical colleges in good standing with the State Board of Medical Registration and Examination, an official body created by and acting for the State to secure good medical service for all the people.

Dr. Arthur Dean Bevan, Chicago, discussed the advantages to medical colleges of State control, and said that proper State control would mean a great deal and be of great advantage to the medical college which was doing good work, and developing along scientific lines. He believed that if every State board represented in the Confederation would attempt to get the profession of its own State back of it and made proper State control effective within five years American medicine could be placed in a position, with the exception of a very few States, where we could say that the American medical student was obtaining the proper medical education; that he had had a proper preliminary and medical education and some practical hospital experience before he was allowed to practice medicine.

Some Evils in the Present System of Medical Education.—Dr. F. C. Waite, Cleveland, Ohio, said the evils of over-production of graduates were self-evident. First, the field being over-stocked, the average income and ade-

quate living are reduced. Second, from this the result must be that the more able members of following generations will shun the profession and its recruits must come from the mediocre. The general tone of the profession will thereby diminish. Third, the average lack of income from reputable and ethical practice in the profession would lead many into quackery and thereby reduce the dignity and respectableness of the profession, and would divert the tendencies of able young men from the profession.

The following papers were also read and discussed: "Would it Add to the Efficiency of Medical Education to have all Teachers Receive a Compensation Commensurate with their Labors and have a Larger Number Devote their Entire Time to Teaching than now Obtains, and could this be Accomplished if Aid were Rendered by the State?" by Dr. Frank Winders, Columbus, Ohio; "Could Examining and Licensing Boards Enforce the Laws Regulating the Practice of Medicine and the Requirements of the Boards more Efficiently if Medical Education were under State Control?" by Dr. Edward Cranch, Erie, Pa.; "If Medical Colleges were Under State Control Would the Medical Profession be More Uniformly and Efficiently Educated and Trained than by the Present System?" by Dr. Royal S. Copeland, New York City; "Some Thoughts on the Supervision of Medical Colleges and the Conducting of State Examinations," by Dr. James A. Egan, Springfield, Ill.

The following officers were elected: *President*, Dr. Charles A. Tuttle, New Haven, Conn.; *First Vice-President*, Dr. James A. Egan, Springfield, Ill.; *Second Vice-President*, Dr. A. B. Brown, New Orleans, La.; *Secretary-Treasurer*, Dr. George H. Matson, Columbus, O.; *Executive Council*: Dr. N. R. Coleman, Columbus, O., *Chairman;* Drs. Charles H. Cook, Natick, Mass.; Joseph C. Guernsey, Philadelphia, W. Scott Nay, Underhill, Vt.; James A. Duncan, Toledo, O.

Chicago was selected as the place for holding the next annual meeting of the confederation.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Illinois State Board of Health.

January 11 to 13, 1911.

ANATOMY.

1. Name the membranes investing the fetus from within outward. From what are these different membranes developed, respectively?
2. What is the direction taken by the nutrient artery in the humerus? What in the radius and ulna?
3. What bone of the foot articulates with the tibia?
4. What is the origin and insertion, action, and nerve supply of the gastrocnemius muscle?
5. What vessels are derived from the arch of the aorta?
6. How is the external jugular vein formed, and how does it terminate?
7. Where are the solitary glands situated, and where are they particularly abundant? To what part of the intestines are Peyer's patches confined, and in what particular part are they largest and most numerous?
8. In fractures of the shaft of the ulna, what muscle causes the outward displacement of the lower fragment?
9. Give the origin of the middle meningeal artery. How does it enter the cranial cavity?
10. What are the ligaments of the temporomaxillary joint?

PHYSIOLOGY.

1. What is oxyhemoglobin? Where is it found?
2. Give location and function of the following centers: thermogenic, thermolytic, and thermotaxic.
3. Describe the functions of nerve cells.
4. Give the physiology of muscular contraction, and state what chemical changes take place in muscular tissue during contraction.
5. Explain the use of the sphygmograph. In what class of diseases would its use be of value?
6. What classes of food should be used by persons in extremely cold climates?
7. Give the physiological action of the bile, and tell how it reaches the intestinal canal.

NEUROLOGY.

1. If locomotor ataxia is sclerosis of the posterior columns of the spinal cord, which are sensory, then why is motion mostly affected?
2. Give symptoms and treatment of sunstroke.
3. What is kleptomania? What is kleptophobia?

MATERIA MEDICA AND THERAPEUTICS.

Name two important remedies commonly employed in the treatment of each one of the following diseases. Give the physical characteristics, dose, mode of administration, and physiological action of one of the remedies in each disease: (1) Facial neuralgia. (2) Chronic Bright's disease. (3) Grand mal. (4) Vomiting of acute gastritis. (5) Typhoid fever. (6) Syphilis. (7) Chronic rheumatism. (8) Anemia. (9) Lobar pneumonia. (10) Malarial fever.

11. Write what you know regarding salvarsan, giving its chemical composition and the quantitative analysis.

PATHOLOGY.

1. What pathological conditions produce bile in the urine?
2. What anatomical changes occur in mitral stenosis?
3. Describe a varicose ulcer. Give the pathology.
4. What is mastoiditis? What are the pathological changes?
5. What pathological conditions cause icterus?

BACTERIOLOGY.

1. Describe the microorganism of erysipelas. Name the media best adapted to its growth.
2. Define mixed and secondary infection.
3. What are the most important distinctions between the *Bacillus typhosus* and *Bacillus coli communis?*
4. Name and describe five diseases due to microorganisms, and describe the microorganism of each.
5. Discuss anaphylaxis.

CHEMISTRY.

1. If chlorine water is exposed to the sunlight, what takes place and what is formed?
2. In what respect does sulphuric acid differ from nitric and hydrochloric acid?
3. What is H_3BO_3? What are the properties of this compound?
4. What one particular element is present in all proteids?
5. How can indican be detected in the urine?

ETIOLOGY AND HYGIENE.

1. What is the etiology of hepatic abscess?
2. What is the etiology of cardiac hypertrophy?
3. What is the etiology of edema of the lungs?
4. What bacterium will invariably be found present in water contaminated by fecal matter?
5. Why is chloride of lime to be preferred to bichloride of mercury and carbolic acid as a disinfectant of excreta?

PHYSICAL DIAGNOSIS.

1. Name the adventitious sounds elicited over the lung area.
2. On percussion you locate an area of dullness over the lung. What might be the auscultatory findings?
3. Define bronchophony, egophony, pectoriloquy, and name conditions in which they may be elicited.
4. Differentiate comas of uremia, alcoholism, and apoplexy.
5. Give the symptomatology and diagnosis of pyonephrosis.

OPHTHALMOLOGY AND OTOLOGY.

1. Define astigmatism and name the varieties.
2. Give symptoms and treatment of episcleritis.
3. Name findings in a case of mastoiditis.

PEDIATRICS.

1. Name varieties of stomatitis and give etiology and treatment of one form.
2. Write a prescription for the daily feeding of an infant three months of age entirely deprived of mother's milk.

PRACTICE.

1. Give method of estimation of free hydrochloric acid in the stomach contents. How would you treat a condition in which there is (*a*) absence of free hydrochloric acid, and (*b*) an excess?

2. In what diseases is the patellar tendon reflex absent? Give treatment in one. What is the significance of the sign?

3. Give the diagnosis and treatment of acute syphilis.

4. Define objective signs and subjective symptoms. Give the signs and symptoms of (*a*) pulmonary consolidation, (*b*) pleural effusion.

5. What is the normal systolic blood pressure? What is the significance of high blood pressure, the dangers, and the treatment?

6. What are the diagnostic blood findings in malaria? Typhoid fever? Syphilis? Anemia?

7. Define dropsy, edema, and anasarca, and give the diagnostic significance of a disease in which any one is a characteristic sign.

8. Define fever and pain, and give the general principles of treatment of any one disease in which either one is a distinguishing characteristic.

9. Give the signs which distinguish mitral regurgitation from aortic regurgitation. Give prognosis in each.

10. Give the diagnosis and treatment of intestinal toxemia.

OBSTETRICS.

1. Briefly outline the duties of a physician following the third stage of labor.

2. Describe method of removing the intracranial fluid of a hydrocephalic child in case of breech presentation.

3. Describe the changes taking place in the ovary during ovulation, also during uterogestation.

4. What are the abnormalities of the fetal appendages which may complicate labor?

5. Discuss the complications that arise as the result of premature detachment of the placenta.

6. Describe bimanual compression of the uterus, and name conditions in which it is useful.

7. What is diastasis of the abdominal muscles? By what means can it be prevented?

8. Name the varieties of inversion of the uterus. Give prognosis.

9. Give etiology, symptoms, and treatment of shock during and after labor.

10. Give cause and treatment of flatulent distention of the abdomen following labor.

GYNECOLOGY.

1. Give the clinical course of gonorrhea in the female. Discuss the curability of gonorrhea.

2. Give characteristic appearance of an erosion of the cervix. How does it differ from a gonorrheal cervicitis or endocervicitis?

3. What affection is commonly confounded with appendicitis in women? Differentiate.

4. Give the diagnosis and radical treatment of rectocele.

5. Give the etiology of coccygodynia. Give symptoms.

6. Give the several mechanical means used for relief of uterine hemorrhage.

LARYNGOLOGY.

1. Describe the tissue changes in two forms of nasopharyngitis.

RHINOLOGY.

1 Differentiate a superficial syphilitic ulcer of the nares from a nonsyphilitic ulcer.

MEDICAL JURISPRUDENCE.

1. Give the average length and weight of the fetus at the end of the seventh month (lunar). At what period are the nails fully developed?

2. Describe three stages in opium poisoning.

SURGERY.

1. Define plastic surgery. Describe four methods by which plastic surgery is performed.

2. Describe the pathological changes that may occur in the stump soon after an amputation.

3. What are the extraordinary dangers attending ligation of the common femoral artery.

4. Give the etiology of cancrum oris. At what period of life is it most common?

5. What is the mortality of lightning stroke? Give symptoms in case when stroke is not immediately fatal.

6. Define the following terms: myelocele, meningomyelocele, syringomyelocele, and meningocele.

7. Describe the operation of avulsion of the supraorbital nerve.

8. Give etiology, symptoms, and treatment of slipping patella.

9. Name the deformities of the chest.

10. Name the surgical diseases of the liver.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

ILLINOIS STATE BOARD OF HEALTH.

January 11 *to* 13, 1911.

ANATOMY.

1. From within outward, the fetus is invested by: (1) The amnion (from ectoderm and mesoderm); (2) allantois (from mesoderm); (3) chorion (from mesoderm and ectoderm); and (4) the decidua.

2. The nutrient artery of the humerus runs downward; that of the radius runs upward; and that of the ulna runs upward; all of them run toward the elbow.

3. The astragalus.

4. GASTROCNEMIUS: The inner head arises from a depression on the upper and back part of the inner condyle of the femur and the adjacent part of the femur; the outer head from an impresion on the external surface of the outer condyle, and from the posterior surface of the femur immediately above the condyle. It unites with the tendon of the soleus to form the tendo Achillis, which is inserted into the lower part of the posterior surface of the os calcis. *Nerve supply*: Internal popliteal. *Action:* It extends the foot, helps to flex the femur on the tibia (when acting from below); and aids in walking, standing, dancing, running, etc.

5. From the arch of the aorta are derived: The innominate, the left common carotid, and left subclavian arteries.

6. The external jugular vein is *formed* by the union of the posterior auricular and the posterior division of the temporomaxillary veins. It *terminates* in the subclavian vein.

7. *The solitary glands* are situated in the mucous membrane of the small intestine and large intestine; they are particularly abundant in the lower part of the ileum. *Peyer's patches* are confined to the small intestine; they are largest and most numerous in the ileum.

8. In fractures of the shaft of the ulna, the lower fragment is displaced outward by the pronator quadratus muscle.

9. The middle meningeal artery arises from the internal maxillary branch of the external carotid artery; it enters the cranial cavity by the foramen spinosum.

10. The ligaments of the temporomaxillary joint are: External lateral, internal lateral, stylomaxillary, capsular, and interarticular fibro-cartilage.

PHYSIOLOGY.

1. Oxyhemoglobin is oxygen in combination with hemoglobin. It is found in the red corpuscles of arterial blood.

2. The *thermogenic* center is concerned in and presides over the production of body heat; the *thermolytic* center in the loss of body heat; and the *thermotaxic* center in the regulation (that is, control of both production and dissipation) of body heat. They are all supposed to be located in the caudate nucleus of the corpus striatum; and the *thermogenic* center is also supposed to be in the tuber cinereum of the optic thalamus.

3. *The functions of the nerve cells* are: (1) To nourish the nerve fibers and processes; (2) to receive, send out, originate, increase, or diminish nerve impulses; (3) to aid in reflexes.

4. Contractility in a muscle can be produced by various stimuli: Mechanical, chemical, electrical, and thermal. During contraction the muscle changes in form, temperature, elasticity, extensibility and electrical condition. There are also chemical changes: Oxygen is consumed, carbon dioxide is set free, sarcolactic acid is developed. The time that elapses between the application of the stimulus and the contraction of the muscle is called the latent period.

5. The sphygmograph is of use to obtain and register the condition of the pulse. It is of value in diseases of the heart and arteries.

6. In extremely cold climates fatty foods should be used.

7. The *physiological action of the bile* is: (1) To assist in the emulsification and saponification of fats; (2) to aid in the absorption of fats; (3) to stimulate the cells of the intestine to increased secretory activity, and so promote peristalsis; and at the same time tend to keep the feces moist; (4) to eliminate waste products of metabolism, such as lecithin and cholesterin; (5) it has a slight action in converting starch into sugar; (6) it neutralizes the acid chyme from the stomach, and thus inhibits peptic digestion; (7) it has a very feeble antiseptic action. The bile is secreted in the liver, it passes by the hepatic duct and cystic duct to the gall-bladder, where it is stored; it then passes down the cystic duct, through the common bile duct, and into the duodenum.

NEUROLOGY.

1. Motion is affected only indirectly; that is, it is due to incoordination or ataxia. The muscular power is not diminished, and the patient can push a kick with considerable force. Loss of sensation makes his muscular movements uncertain.

2. See French's "Practice of Medicine" (1910), page 1004; or Osler's "Practice of Medicine" (1909), page 386.

3. *Kleptomania* is an impulse to steal; some say that the impulse is irresistible, and some say that it is an insane impulse.

Kleptophobia is dread of becoming a thief.

MATERIA MEDICA AND THERAPEUTICS.

1. For *facial neuralgia*: Quinine and nux vomica. *Strychnine sulphate* is a crystalline, odorless, very bitter substance, dose gr. 1/60, generally given in tablet form. Strychnine is a bitter tonic, stimulates appetite, secretion, and digestion, increases peristalsis, stimulates the vasomotor centers, and so raises arterial tension; it stimulates both accelerator and inhibitory nerves of the heart. All the functions of the spinal cord are exalted by strychnine, reflex, motor, vasomotor, and sensory. Large doses cause dilated pupils, irregular and jerky respiration, increased reflexes.

2. For *chronic Bright's disease:* Mineral waters and milk.

3. For *grand mal:* Potassium bromide and opium. *Opium* occurs in irregular lumps, bitter, narcotic, and of a dark-brown color; dose gr. ¼ of morphine sulphate, given hypodermically. It is analgesic, hypnotic, diaphoretic, narcotic, a respiratory and cardiac stimulant (later a depressant), it checks most secretions (not perspiration), it stimulates the brain, and contracts the pupil.

4. For *vomiting of acute gastritis:* Arsenic and bismuth. *Arsenic* is best given in ♏ij to v doses of Fowler's solution, in water, after meals. Arsenic is escharotic; irritant, tonic; increases cardiac action, respiratory power, intestinal secretions, and peristalsis; produces edema, itching, diarrhea, epigastric pain, irritable and feeble heart.

5. For *typhoid fever:* Brand bath and salol. For the former see French's "Practice of Medicine" (1910), page 114; or Osler's "Practice of Medicine" (1909), page 100.

6. For *syphilis*: Mercury and potassium iodide. *Mercury* is best given as the protiodide, in pills of gr. 1/6, one after each meal, increasing by one pill every third day till the teeth get sore or the bowels are disturbed. *Mercury* is a fluid, silver-like metal, insoluble in the ordinary solvents, odorless, and tasteless; it is a tonic, alterative, purgative, antiphlogistic, and sometimes corrosive.

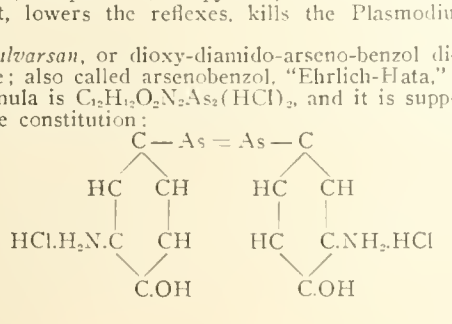
7. For *chronic rheumatism:* Sodium salicylate and salicylic acid. *Salicylic acid* is an odorless, sweetish but acrid crystalline powder, soluble in water containing borax, or in alcohol or in ether; dose gr. viijss, best given in solution, flavored. It is "antiseptic, irritant, strongly cholagogue, antipyretic, diaphoretic, diuretic (markedly increasing the excretion of uric acid). In exceptional instances skin eruptions are caused, and in some individuals a train of symptoms analogous to those of cinchonism and designated as *salicylism,* results from the use of salicylic preparations."

8. For *anemia:* Arsenic and iron. For *arsenic,* see 4.

9. For *lobar pneumonia:* Fresh air and aconite. *Aconite,* best given in ♏vij doses of the tincture. *Aconite* first stimulates and then paralyzes heart and also sensory nerves, lowers blood pressure, dilates peripheral bloodvessels, is a respiratory sedative, reduces body temperature, is a diuretic and diaphoretic.

10. For *malarial fever:* Quinine and arsenic. *Quinine:* See French's "Practice of Medicine" (1910), page 248. *Quinine sulphate* is a white, crystalline powder, very bitter, moderately soluble in acidulated water. It is a bitter tonic, promotes the flow of saliva and gastric juice, aids digestion, may produce headache and tinnitus aurium, is an antiseptic, antiperiodic, antipyretic; it is also a cardiac depressant, lowers the reflexes, kills the Plasmodium malariæ.

11. *Salvarsan*, or dioxy-diamido-arseno-benzol di-hydrochloride; also called arsenobenzol, "Ehrlich-Hata," or 606. Its formula is $C_{12}H_{12}O_2N_2As_2(HCl)_2$, and it is supposed to have the constitution:



It is a bright yellow powder, slowly soluble in water, has an acid reaction, contains about 34 per cent. of arsenic, is used in the treatment of syphilis, but is in the experimental stage only. It would be well not to give up the older remedies yet, and not to believe all the newspaper reports on this remedy. Up to the present it seems to be uncertain whether to use the substance in a solution or in an emulsion, also whether it should be administered into a muscle, into a vein, or under the skin. Further, there are certain contraindications; and bad results have followed its use (or abuse).

PATHOLOGY.

1. *Bile may be present in the urine,* in: Obstruction of the bile ducts, whether due to catarrhal jaundice, parasites, biliary calculi, or pressure from the outside such as tumors in liver, gall-bladder, stomach or pancreas; also in pernicious anemia, severe malarial intoxication, typhoid fever.

2. See French's "Practice of Medicine" (1910), page 593; or Osler's "Practice of Medicine" (1909), page 808.

3. See Rose and Carless' "Sugery" (1908), page 93; or Da Costa's "Surgery" (1908), page 162.

4. See Rose and Carless' "Surgery" (1908), page 885.

5. *Icterus may be caused by:* Obstruction of the bile ducts (see QUESTION 1); infectious diseases such as influenza, typhoid, malaria, scarlet fever, pneumonia, acute yellow atrophy of the liver; poisoning by arsenic, chloral, chloroform, phosphorus, mercury, ether, potassium, chlorate; diseases of the liver, such as carcinoma, abscess, cirrhosis.

BACTERIOLOGY.

1. *Erysipelas* is caused by the *Streptococcus erysipelatis;* it appears in chains of varying lengths or in tangled masses, the presence or absence of oxygen does not seem to be of much importance, it grows at room temperature, and has the cultural characteristics of the *Streptococcus pyogenes.* This latter is a micrococcus, of spherical shape, and arranged in chains of about thirty or forty cocci (in liquid media), but the chains are much shorter in solid media. Each coccus is about one-half to two mikrons in diameter. It is not motile, does not form spores, does not liquefy gelatin, and stains readily with the ordinary anilin dyes, and by Gram's method. It grows very well on blood serum and milk, also on gelatin, and agar.

2. By *mixed infection* is meant the infection of a part by the entrance of more than one kind of pathogenic microorganism at the same time. By *secondary infection* is meant that a part which is already infected is invaded by another kind of pathogenic microorganism.

3. *To distinguish the typhoid bacillus from the colon bacillus:* (1) On gelatin plates, the colonies of typhoid develop more slowly than those of colon bacillus. (2) The colon bacillus causes fermentation with production of gas in media which contain sugar; the typhoid bacillus does not. (3) The colon bacillus produces a strong acid reaction and coagulates milk within twenty-four to forty-eight hours; the typhoid bacillus does not coagulate milk. (4) In peptone solution the colon bacillus produces indol; the typhoid bacillus does not. (5) The typhoid bacillus gives the Widal reaction with typhoid serum; the colon bacillus does not.

4. *Five diseases due to microorganisms:* Typhoid, syphilis, diphtheria, erysipelas, and tetanus. For *description of these diseases,* see French's "Practice of Medicine" (1910), pages 65, 425, 180, 218, and 414; or Osler's "Practice of Medicine" (1909), pages 57, 265, 192, 210, and 258.

Bacillus typhosus is a rod-shaped organism, with rounded ends, is from 2 to 4 microns in length and about three-fourths of a micron in breadth; it does not stain by Gram's method, but stains with all the anilin dyes; it has flagella, no spores, is aerobic and facultative anaerobic, and is motile.

The cause of syphilis is the *Treponema pallidum.* It is a very slender spiral, about 4 to 20 microns in length, with very close and regular twins, the curves vary in number from three or four to twelve to twenty. At each pole is a fine flagellum. It can move forward and backward, and also rotate on its axis. It is not settled whether division is transverse or longitudinal. It has not yet been cultivated on artificial media.

The *characteristics of the bacillus of diphtheria*: The bacilli are from 2 to 6 mikrons in length, and from 0.2 to 1.0 mikron in breadth; are slightly curved, and often have clubbed and rounded ends; occur either singly or in pairs, or in irregular groups, but do not form chains; they have no flagella, are nonmotile, and aerobic; they are noted for their pleomorphism; they do not stain uniformly, but stain well by Gram's method and very beautifully with Loeffler's alkaline-methylene blue.

For *erysipelas,* see QUESTION 1.

The *bacillus of tetanus* is characterized by its peculiar spore, formed at one end of the bacillus, and giving it the appearance of a pin; it is purely anaërobic, and cannot be developed at all in the presence of oxygen. It generally comes from the soil, and is found in penetrating wounds. It appears in two forms, the spore-bearing form, as described above, and the vegetative form, which is a short bacillus with rounded ends, and which may occur singly or in pairs, or may form long filaments. It grows in gelatin stab cultures in the middle of the medium, and the colonies look something like a fir tree; its growth is slow, and a disagreeable odor is at the same time emitted. In bouillon it grows near the bottom of the tube, and produces gases.

5. *Anaphylaxis* is a condition of supersensitization induced by the injection of a serum. It is the opposite of prophylaxis, and in place of rendering the person injected immune the serum has made him particularly susceptible. It has been followed in some instances by alarming symptoms, such as: Heart failure, collapse, convulsions, coma.

CHEMISTRY.

1. If chlorine water is exposed to the sunlight it is decomposed; the chlorine unites with the hydrogen of the water to form hydrochloric acid, and the oxygen is set free. Thus: $2Cl_2 + 2H_2O = 4HCl + O_2$.

2. Sulphuric acid (H_2SO_4) is dibasic, whereas nitric (HNO_3) and hydrochloric (HCl) acids are monobasic. Further, *hydrochloric acid:* When pure this is a colorless gas with a sharp, penetrating, and irritating odor; it is very soluble in water; it does not support combustion nor does it burn in air; it is very corrosive. The ordinary hydrochloric acid is a solution of this gas in water, and is found in three varieties: the commercial, the pure, and the dilute acids. *Sulphuric acid* is a colorless, thick, oily liquid, odorless, very corrosive; has a great tendency to unite with water; it chars organic matter. *Nitric ocid* is a colorless or faintly yellow liquid, has a sour taste, a suffocating odor, and is very corrosive. It is a strong oxidizing agent, and stains animal tissues yellow.

3. H_3BO_3 is the formula for one molecule of boric acid. *Properties:* White glistening plates, unctuous to the touch; odorless; having a slightly bitter taste, and without corrosive or poisonous action; soluble in water; an antiseptic; when heated it forms successively metaboric acid and pyroboric acid.

4. All proteids contain carbon, hydrogen, oxygen, and nitrogen; the last is probably the element referred to by the examiner.

5. *Test for indican in the urine:* The urine is mixed with one-fifth its volume of 20 per cent. solution of lead acetate and filtered. The filtrate is mixed with an equal volume of fuming hydrochloric acid containing 3:1000 of ferric chloride, a few drops of chloroform are added, and the mixture strongly shaken one to two minutes. With normal urine the chloroform remains colorless, or almost so; but if an excess of indoxyl compounds be present the chloroform is colored blue, and the depth of the color is a rough indication of the degree of the excess.

ETIOLOGY AND HYGIENE.

1. See French's "Practice of Medicine" (1910), page 851; or Osler's "Practice of Medicine" (1909), page 563.

2. See French's "Practice of Medicine" (1910), page 613; or Osler's "Practice of Medicine" (1909), page 822.

3. See French's "Practice of Medicine" (1910), page 680; or Osler's "Practice of Medicine" (1909), page 616.

4. In water contaminated by fecal matter the *Bacillus coli communis* will be found.

5. Chloride of lime is to be preferred to bichloride of mercury and carbolic acid as a disinfectant of excreta, because the two latter unite with and coagulate albuminous matter, and so are unable to penetrate.

PHYSICAL DIAGNOSIS.

1. The adventitious sounds which may be elicited over the lung area are:

(1) Râles
- Dry
  - Sonorous
  - Sibilant
- Moist
  - Crepitant
  - Subcrepitant
  - Gurgling
    - Large or cavernous
    - Small or mucous

(2) Metallic Tinkling; (3) Succussion Splash; and (4) Pleuritic Friction Sounds.

2. There might be: Bronchial or harsh respiration, absent respiration, bronchophony, or absent voice.

3. *Bronchophony*, or the voice concentrated near the ear, raised in pitch and in intensity, denotes complete consolidation of the pulmonary tissue in those parts in which the sound is abnormally present.

Pectoriloquy is complete transmission of the voice to the ear, the articulated words being distinctly recognized. It has a close resemblance to the resonance heard over the larynx in health. Its presence indicates either a pulmonary cavity or more complete consolidation—in other words, an exaggerated bronchophony.

Egophony is a modification of bronchophony, consisting in tremulousness of the voice, its character nasal or bleating, somewhat suggestive of the cry of a goat. When heard it may be considered a sign of pleurisy with slight effusion, or pleuropneumonia.

(Hughes' *Practice of Medicine.*)

4.

APOPLECTIC COMA.	UREMIC COMA.	ALCOHOLIC COMA.
Deep coma; sudden onset. If any injury, only a scalp wound.	Deep coma. Slow onset unless convulsions have preceded the coma.	Can be aroused by supraorbital pressure unless very profound.
Pupils unequal or dilated. Contracted in hemorrhage into the pons.	Albuminuric retinitis.	Pupils normal or somewhat dilated.
Pulse full and slow, often arteriosclerotic high-tension pulse.	Pulse rapid.	Pulse more rapid than normal and full.
Respiration slow and irregular.	Respiration frequent and irregular.	Regular respiration.
Temperature higher on paralyzed side, but lower in rectum.		May be low or normal.
Urine contains trace of albumin, but may be same as in uremia.	Urine shows albumin, casts, and low urea percentage.	Normal.
Hemiplegia with convulsions on one side.		

5. See French's "Practice of Medicine" (1910), page 935; or Osler's "Practice of Medicine" (1909), page 704.

OPHTHALMOLOGY AND OTOLOGY.

1. *Astigmatism* "is that refractive condition of the eye in which there is a difference in the degree of refraction in different meridians; each of the principal meridians has, therefore, a different focus." There are two varieties: (1) *Regular* and (2) *Irregular.*

2. *Episcleritis. Symptoms:* "There are some discomfort, lachrymation, slight pain, and photophobia. A flat or somewhat raised inflammatory patch of a purple color is seen adjacent to the cornea or a short distance from the limbus. There is no tendency to suppuration or ulceration. After a few weeks the purple spot will disappear; but others are apt to take its place; in this way the process may encircle the cornea. Owing to this tendency to relapses the disease often lasts many months. Sometimes some discoloration of the sclera remains, but there is no interference with vision Occasionally the adjacent portion of the cornea is implicated. The disease may resemble a marked case of phlyctenular conjunctivitis; it may merge gradually into scleritis.

"Treatment should be of a sedative nature: Warm fomentations, leeches to the temple, and gentle massage; if photophobia be pronounced, smoked coquilles. Subconjunctival injections of bichloride of mercury (1:5,000) have recently been recommended. The ointment of the yellow oxide of mercury is often of value. When there is a rheumatic history, sodium salicylate in large doses (gr. x to xv every two hours) should be given. Other constitutional disorders should be prescribed for. Iodide of potassium may be ordered, also hypodermic injections of pilocarpine."—(*May's Diseases of the Eye.*)

3. ACUTE MASTOIDITIS. *Symptoms:* Tenderness, pain, swelling and redness over the mastoid; bulging of the superior and posterior parts of the auditory canal; temperature variable, from normal up to about 104° F.

PEDIATRICS.

1. See French's "Practice of Medicine" (1910), page 723; or Osler's "Practice of Medicine" (1909), page 434.

2. For an infant of three months, Winters advises the following:

Take the upper eleven ounces from a quart of milk, 10 hours after milking.
Milk-sugar, about 7½ teaspoonfuls.
Lime-water, 4 ounces.
Filtered water, enough to make one quart.
Quantity at each feeding, 3 ounces.
Eight feedings, at 6, 8½, 11 A.M.; 1½, 4, 6½, 9, and 12 P.M.

PRACTICE.

1. *Töpfer's Method of estimating free HCl in stomach contents:* "Three samples of 10 c.c. each are separately titrated with N/10 NaHO solution; in (1) using phenolphthalein as an indicator, and carrying the addition of alkali to a distinct red, not to faint pink, as is usual. This gives the total acidity (A), made up of free HCl (L), protein HCl (C), and organic acids and salts (O). In (2) alizarin is used as an indicator, to pure violet. This gives the acidity due to (L + O), and, therefore, the result of (2), subtracted from that of (1), leaves the value of (C) = protein HCl. In the third sample (3) dimethylamido-azobenzene is used as an indicator, to yellow. This gives the value of (L) alone, i. e., free hydrochloric acid. If the value of (O) be desired, it may be obtained by subtracting the result of (3) from that of (2). In each of the above titrations the number of c.c. of alkaline solution used, multiplied by 0.0365, gives the result, express in percentage of HCl." (Witthaus' *Manual of Chemistry.*)

(*a*) and (*b*) See French's "Practice of Medicine" (1910), pages 786 and 785; or Osler's "Practice of Medicine" (1909), page 495.

2. The *patellar reflex is absent* in: Locomotor ataxia, anterior poliomyelitis, Landy's paralysis, Friedreich's ataxia, transverse myelitis sometimes, and sometimes in chorea, diabetes, and diphtheria.

For treatment of locomotor ataxia, see French's "Practice of Medicine" (1910), page 1088; or Osler's "Practice of Medicine" (1909), page 804.

The *significance of the absence of this reflex* is that there is something wrong somewhere in the reflex arc concerned (a lesion involving the motor or sensory nerves, the posterior columns of the spinal cord, the anterior cells or the end plates in the muscles).

3. See French's "Practice of Medicine" (1910), pages 433 and 435; or Osler's "Practice of Medicine" (1909), pages 278 and 279.

4. *Objective signs* are such as the physician sees or determines for himself. *Subjective symptoms* are such as the patient tells us.

See French's "Practice of Medicine" (1910), pages 158 and 717; or Osler's "Practice of Medicine" (1909), pages 172 and 645.

5. The *normal systolic* blood pressure is about 120 to 145. *Abnormally high* blood pressure is found in chronic interstitial nephritis, arteriosclerosis, myocarditis, uremia, gout, cerebral hemorrhage, lead poisoning, and sometimes in acute nephritis. The dangers are hemorrhage, apoplexy, coma, and death. For treatment of the conditions see French's "Practice of Medicine" (1910), pages 644 and 932; or Osler's "Practice of Medicine" (1909), pages 853 and 700.

6. In *malaria* the plasmodium will be found. In *typhoid* the Widal reaction will (probably), be present. In *syphilis* the treponema pallidum may be found in the serum. In *anemia* there will be diminution in the number of red corpuscles, and they may be misshapen, and a few may be nucleated.

7. *Edema* is the accumulation of serous fluid in the connective tissues.

Dropsy is the accumulation of serous fluid in the serous cavities.

Anasarca is a general edema, or a combination of edema and dropsy.

Ascites is an accumulation of serous fluid within the abdominal cavity. See French's "Practice of Medicine" (1910), page 889; or Osler's "Practice of Medicine" (1909), page 589.

8. *Fever* is a condition characterized chiefly by a rise of body temperature and a quickened pulse.

Pain is suffering, either bodily or mental. Pain is a distinguishing characteristic in biliary colic. See French's "Practice of Medicine" (1910), page 873; or Osler's "Practice of Medicine" (1909), page 555.

9.

AORTIC DISEASE.	MITRAL DISEASE.
Symptoms are mainly due to anemia, viz.:	Symptoms are mainly due to venous congestion, viz.:
1. Pallor.	1. Cyanosis.
2. Throbbing of the carotids.	2. May get pulsation in the veins of the neck.
3. Attacks of an "angina pectoris" type of pain.	3. Sudden attacks of severe dyspnea—actual acute pain is rare.
4. Breathlessness on slight exertion.	4. Breathlessness, but often present without exertion.
5. Nervous symptoms are prominent, owing to cerebral anemia. Syncopal attacks are also common.	5. Pulmonary symptoms are most prominent, *i.e.* cough in the morning, chronic bronchitis, hemoptysis, dilated right side of heart, and later symptoms due to tricuspid leakage.
7. The *left ventricle* is usually much hypertrophied.	7. The *left auricle* is somewhat hypertrophied, but the main hypertrophy is that of the *right ventricle.*

—(From Wheeler and Jack's *Handbook.*)

And see French's "Practice of Medicine" (1910), pages 588, 599, and 602; or Osler's "Practice of Medicine" (1909), pages 805, 799, and 814.

10. See French's "Practice of Medicine" (1910), page 996; or Osler's "Practice of Medicine" (1909), page 381.

OBSTETRICS.

1. See Williams' "Obstetrics" (1909), pages 340 and 346; or Hirst's "Obstetrics" (1909), page 364.

2. See Williams' "Obstetrics" (1909), pages 795 and 465; or Hirst's "Obstetrics" (1909), page 561.

3. See Williams' "Obstetrics" (1909) pages 93 and 97; or Hirst's "Obstetrics" (1909), pages 61 and 78.

4. *Abnormalities of the fetal appendages which may complicate labor* are: Shortness of the cord, cord twisted round neck of fetus, adhesion of the membranes, prolapsed cord, placenta prævia, premature separation of the placenta, retained placenta, adherent placenta, premature rupture of the membranes, toughness of the membranes, deficiency of liquor amnii.

5. See Williams' "Obstetrics" (1909), page 807; or Hirst's "Obstetrics" (1909), page 583.

6. See Hirst's "Obstetrics" (1909), page 587.

7. See Williams' "Obstetrics" (1909), pages 170 and 564; or Hirst's "Obstetrics" (1909), pages 620 and 686.

8. *Varieties of inversion of the uterus* are: (1) A depression in the fundus; (2) partial inversion, in which the fundus protrudes beyond the os; (3) complete inversion, in which the uterus is turned inside out, and may project from the vulva.

And see Williams' "Obstetrics" (1909), page 824; or Hirst's "Obstetrics" (1909), page 614.

9. See Hirst's "Obstetrics" (1909), pages 621 and 642. *Treatment of shock:* "If the severity of the symptoms is such as to warrant the most active treatment, the pillows are removed from the bed, the foot of the bedstead is elevated, and the patient's arms and legs are bandaged (autotransfusion). Warm saline infusion is then introduced into the rectum and subcutaneously beneath the breasts. Stimulants must be used with care, owing to their tendency to cramp the heart under these circumstances. Ammonia may be injected into a vein, and camphorated oil subcutaneously. Absolute quiet is demanded. Feeding must not be neglected in these cases. At first it may require limitation to sips of brandy and coffee every fifteen minutes; after some reaction has set in, beef juice, panopeptone, mutton broths, etc., may be substituted. In case of vomiting the patient may be nourished by the rectum with enemata of hot water containing whiskey and pancreatinized milk or panopeptone."—(From Edgar's *Practice of Obstetrics.*)

10. See Hirst's "Obstetrics" (1909), page 686.

GYNECOLOGY.

1. See Rose and Carless' "Surgery" (1908), page 139; or Da Costa's "Surgery" (1908), page 1169.

2. *Erosions of the cervix* are of a red or purple color, and are generally confined to the part immediately around the external os, but may extend over the entire vaginal part of the cervix. It is either smooth and soft, or has an irregular surface (papillary projections).

In *gonorrheal endocervicitis* the discharge contains gonococci; these are not present in simple cervical erosions.

3. Inflammation of the right ovary is most likely to be confounded with appendicitis in women.

In *appendicitis* the pain is of sudden onset and is localized in the right iliac fossa; there is abnormal rigidity, chiefly of the right rectus muscle, and tenderness at McBurney's point; there are usually fever, nausea, vomiting, and constipation.

In *inflammation of the right ovary* the pain is not localized, but may be bilateral, and spreads to the vagina and rectum; there is no tenderness at McBurney's point; it is usually worse just before the menstrual period, which sometimes affords relief; on vaginal examination the ovary is found to be tender.

4. *Rectocele* is diagnosed by the presence of a tumor on the posterior wall of the vagina which may even protrude through the vaginal orifice; the perineum is torn, and a finger introduced into the rectum passes easily into the rectocele. The treatment consists in the repair of the perineum by Emmett's operation. See Hirst's "Obstetrics" (1909), pages 868, etc.

5. Coccygodynia. *Etiology*: Childbearing, excessive horseback riding, uterine or ovarian disease, neurasthenia, and trauma. *Symptoms:* Severe neuralgic pain in the region of the sacrococcygeal articulation; this pain is increased by movement (particularly rising from a low seat), defecation, or coitus

6. *Mechanical means for relief of uterine hemorhage:* Vaginal and uterine tamponade, hot douches.

LARYNGOLOGY.

1. In *atrophic nasopharyngitis* the nasopharyngeal mucous membrane is atrophied, and some of the normal tissues are replaced by connective tissue; the ciliated epithelium is replaced by squamous epithelium.

In *hypertrophic nasopharyngitis* the nasopharyngeal mucous membrane is swollen and is generally red; the connective tissue is increased, and so, too, are the lymphatic and glandular elements.

RHINOLOGY.

1. In *syphilitic ulcer of the nares* the other manifestations of syphilis will soon appear; the bone will soon be involved; there will be considerable pain and odor; the ulcer will have regular margins and but little congestion. In *non-syphilitic ulcer* such will not be the case.

MEDICAL JURISPRUDENCE.

1. At the end of the seventh lunar month the fetus is said to be from 35 to 38 centimeters long and to weigh 1150 to 1200 grams. The nails are fully developed toward the end of the eighth month.

2. The *symptoms of poisoning by opium* are as follows: "At first there is usually a period of excitation, marked by restlessness, great physical activity, loquacity, and hallucinations. The patient then becomes weary, dull, and drowsy; he yields to the desire for sleep, from which at first he may be roused. The lips are livid, the face pale, the pupils contracted, and the surface bathed in perspiration. The condition of somnolence rapidly passes into narcosis. The patient cannot be roused, and lies motionless and senseless, with completely relaxed muscles. The pulse, at first full and strong, becomes feeble, slow, irregular, and easily compressible; the respiration slow, shallow, stertorous, and accompanied by mucous râles. The patient rapidly becomes comatose, and, in fatal cases, dies in from forty-five minutes to fifty-six hours, usually in from twelve to eighteen hours. In cases of recovery after the stage of narcosis, the pulse and respiration gradually return to the normal, and the condition of coma passes into one of deep sleep, lasting twenty-four to thirty-six hours."—(Witthaus' *Essentials of Chemistry and Toxicology.*)

SURGERY.

1. "*Plastic surgery* includes operations for the repair of deficiencies, for the replacement of lost parts, for the restoration of function in parts tied down by scars, and for the correction of disfiguring projections."

See Rose and Carless' "Surgery" (1908), page 96; or Da Costa's "Surgery" (1908), page 1089.

2. "The following features are characteristic of a good stump—and also indicate the changes which follow successful amputation.

"*Skin.*—Not adherent, except at cicatrix. Capable of withstanding (and, preferably, accustomed to withstand) pressure. Plentifully supplied with blood.

"*Muscles.*—The muscles of a stump are not retained as such—the muscle tissue disappears in greater part and is replaced by fibrous tissue. Exceptionally some muscle tissue remains and continues to function. The mass of fibrous tissue which replaces it, however, serves a useful purpose in padding over the end of the bone. In brief, muscle tissue tends to decrease—and fibrous tissue to increase. Muscles and tendons either become incorporated in the cicatrix, form new attachments to bone, or retract out of the way.

"*Bone.*—The ends of the bones become rounded and the medullary canals closed by fibrous tissue. The end of the bone may either dwindle and atrophy, or the periosteum may, exceptionally, deposit an excess of bone. The shaft of the bone in an amputated limb also atrophies somewhat.

"*Cartilage.*—Following a disarticulation, the articular cartilage left atrophies and sometimes entirely disappears.

"*Nerves.*—Also atrophy to a greater or less extent. The ends generally become bulbous, but give no trouble unless they become adherent to bone or cicatrix.

"*Vessels.*—Share in the general atrophy, and dwindle to a size commensurate with the parts to be supplied. Ligated trunks become obliterated to their nearest branch. Collateral circulation is established."—(Bickham's *Operative Surgery.*)

3. Ligation of the common femoral artery was formerly followed by numerous cases of gangrene.

4. *Cancrum oris* is probably caused by streptococcus pyogenes or some other saprophytic bacteria. It is most common in childhood.

5. See Da Costa's "Surgery" (1908), page 1255.

6. These are the four forms of *spina bifida:* "(1) *Spinal meningocele*, in which only the membranes, filled with cerebrospinal fluid, are protruded. (2) *Meningomyelocele*, the form most commonly met with clinically, in which the cord and some of the spinal nerves are protruded, and spread out over the inner aspect of the sac. (3) *Syringomyelocele*, in which there is a dilatation of the central canal in the protruded part of the cord. In these three forms the protrusion may be covered by healthy skin, or by a thin, smooth, translucent membrane through which the contents are visible. (4) In the *myelocele* this skin, as well as the vertebral arches and membranes, is absent, and the cord lies exposed on the surface."—(Thomson and Miles' *Surgery.*)

7. See Rose and Carless' "Surgery" (1908), page 383; or Da Costa's "Surgery" (1908), page 680.

8. See Rose and Carless' "Surgery" (1908), page 633; or Da Costa's "Surgery" (1908), page 606.

9. *Deformities of the chest:* General diminution in size, general enlargement, diminution in anteroposterior diameter of thorax, increase in anteroposterior diameter, pigeon breast, Harrison's sulcus, fullness of supraclavicular fossa, depression of one supraclavicular fossa, elevation of one shoulder, uniform dilatation of one side of thorax, uniform contraction of one side of thorax, lateral curvature of the spine, angular curvature of the spine, extreme depression of the lower part of the sternum, asymmetrical diminution in size of a part of the thorax, asymmetric localized bulging. The thoracic walls may be defective at various points, there may be a fissure or defect of the sternum, cervical ribs may be met with, also congenital displacement upwards of scapula. The pectoral muscles may be absent, there may also be absence of the nipple, or an extra nipple, or amazia, or polymastia.—(From Quain's *Dictionary of Medicine.*)

10. *Surgical diseases of liver:* Abscess, cancer, cirrhosis, cysts, disclocated enlargement, hydatid, prolapse, rupture, sarcoma, syphilis, tumors, and ptosis.

New Instruments.

A VACCINE SHAKER.

By C. J. BARTLETT, M.D.,

NEW HAVEN, CONN.,

PATHOLOGICAL LABORATORY, YALE MEDICAL SCHOOL.

THE piece of apparatus here described and illustrated has been found useful in this laboratory. As it is employed chiefly in shaking bacteria in sealed test tubes or bottles in the preparation of vaccines, it has come to be called the "vaccine shaker." Credit for it is due to Mr. A. D. Francis, the technician of the laboratory. Being of an ingenious turn of mind and a believer in labor-saving apparatus, after shaking a few tubes of vaccine by hand, he thought of and made the shaker. As none of the dealers in laboratory supplies appears to carry anything of the sort, except the expensive and quite elaborate sputum bottle shakers, and as visitors from other laboratories have shown considerable interest in it, it has seemed best to describe it for the benefit of others who may find such apparatus of value. It is made to fit on to the ordinary water centrifuge in

place of the regular centrifuge head (tube arm and stem, K). The speed of the electric centrifuges, unless unusually slow, would be too great for it to be used on them.

The shaker consists of a wheel which is rotated by the centrifuge and which has an eccentrically

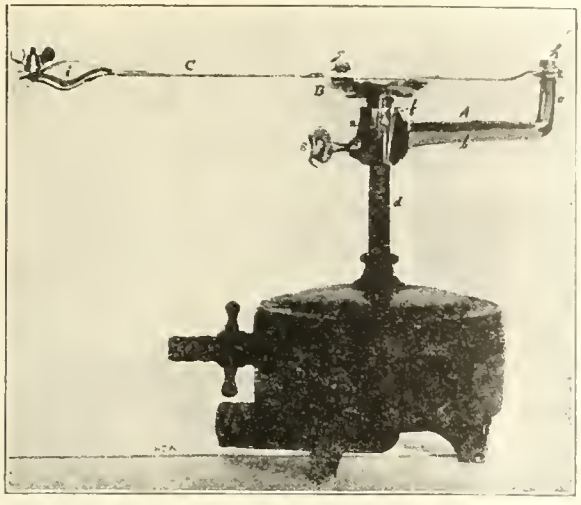


Fig. 1.

placed vertical bolt. This bolt moves a metal arm back and forth, one end of this arm being stationary and the other end carrying the test tube. For the benefit of those who may wish to make use of the apparatus, a somewhat detailed description will be given with the measurements which have been found satisfactory. It is made of brass, nickel plated.

The shaker consists of three parts: an arm support (A), a wheel (B) and an arm (C). The arm support is made up of the body (a), the horizontal portion (b) and a vertical part (c) at its distal end. The body, 2½ or 3 cm. in diameter, has a vertical hole through it. The lower part of this hole is just large enough so it will slip readily down on to the upright standard of the water centrifuge (d) after the centrifuge head (k) has been removed. The body is held in place by a thumbscrew (e) at its lower part. The upper half of the hole through the body is 3 or 4 mm. larger in diameter than the lower half. Through the side of the upper part of the body is a small set screw (f) which projects far enough into the central opening to hold the wheel in place.

The horizontal part of the arm support is 13 mm. in width and 16 mm. vertically and tapers so that it is somewhat smaller at its distal end. From the center of the hole in the body to the end of the horizontal part is 11 cm. The vertical portion of the arm support is about 1 cm. in diameter and it extends up from the horizontal part 4 cm. The upper 1 cm. of this consists of a central bolt (h), 5 mm. in diameter, with thread and nut. Just below this the vertical part is expanded into a shoulder, 2 cm. wide, with a flat surface on which the end of the arm plays.

The wheel, which is solid, is about 6.5 cm. in diameter. Its upper flat surface has a vertical eccentric bolt (g) a short distance from one edge. This is a little over 1 cm. long, 5 mm. in diameter, with thread and nut. A wide steel washer, 3 mm. high, fits over the lower part of this. Above this washer there is, fitting loosely around the bolt, a small hollow roller, 5 mm. high and a little over 7 mm. in diameter, and above this the nut. On the under surface of the wheel is a vertical metal stem, firmly attached to the center of the wheel, of such diameter that it just fits loosely into the upper half of the vertical hole through the body (a). From the upper flat surface of the wheel to the lower end of this stem is 3 cm. In the center of this stem is a vertical central hole, 6 mm. in diameter, extending from below nearly the whole length of the stem. The lower end of this stem is filed to the same shape as that of the lower end of the stem of the centrifuge head, in the place of which it is to fit. Two or three mm. above the lower end of the stem is ground a shallow, circular groove into which the set screw (f) projects a short distance.

The arm (C) consists of a thin, flat piece of brass, 34 cm. long, about 3 mm. thick and 2 cm. wide. This has a hole near one end large enough so that it fits loosely over the bolt (h). Just beyond the shoulder around this bolt the arm is bent down about 1 cm. as shown in the cut. Beginning about 7.5 cm. from this hole, there is a longitudinal slit in the arm, 6.5 cm. long and 8 mm. wide. In this fits the roller around the bolt of the wheel. At the other end of the arm is a tube clutch (i). The lower part of this consists of the arm bent into the shape shown in the cut. The upper part of the clutch is made of a strip of spring brass, about ½ mm. thick. From the end of the lower part of the clutch a small bolt with a thread extends up through a hole in the upper part and has a thumb screw to clamp them together.

The stem of the wheel is fixed in the body of the arm support as shown in cut; the body simply fits down over the upright piece of the water motor with the stem in the place of the stem of the centrifuge head and is clamped there by the thumb screw (e). The tube is held in the horizontal position by

Fig. 2.

the tube clutch. Any desired speed may be obtained by varying the flow of water through the centrifuge. The apparatus can be made at a small expense. It can be put in place or removed at any time in a few seconds.

Incidentally it may be added that in shaking bacteria in liquid with sterile beads to secure a uniform suspension preparatory to counting them, it has been found more convenient to use a small bottle with tightly fitting rubber cap rather than a sealed test-tube or capsule.

Antitryptic Power of the Cerebrospinal Fluid.—Satta and Gastaldi found that in tuberculous and in epidemic cerebrospinal meningitis the cerebrospinal fluid has an antitryptic property. This is lacking in the normal fluid, and in that of cases of other diseases, including those of the central nervous system.—*Biochimica e Terapia Sperimentale*

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading, but it must be with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

Medical Items.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week of March 18, 1911.

	Cases	Deaths
Tuberculosis Pulmonalis	681	164
Diphtheria	370	34
Measles	680	17
Scarlet Fever	546	31
Smallpox	—	—
Varicella	209	—
Typhoid Fever	20	4
Whooping Cough	120	5
Cerebrospinal Meningitis	6	7
Malarial Fever	—	—
Totals	2,632	262

Treatment of Eclampsia.—Hirst states that the proper obstetrical treatment is as follows: If the woman is pregnant or in labor, nothing should be done except to puncture the membrane, which more quickly and decidedly reduces blood pressure than anything else. Any form of *accouchement forcé* adds to the risk and increases the mortality. After puncture of the membrane and with the active eliminative treatment an easy spontaneous labor is the rule within eight hours.—*American Journal of Obstetrics and Diseases of Women and Children.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended March 17, 1911.

VAGARIES OF THE PNEUMOCOCCUS.

BY WM. HANNA THOMSON, M.D., LL.D.,

NEW YORK.

IN the afternoon of June 23 last, having been in my usual state of good health, I suddenly felt a sense of great muscular weariness which I could not explain. Supposing that I had been too sedentary I concluded to take a stroll of about a mile to walk it off. When I returned I took my temperature and found it registered 102° F. under the tongue, and meantime the sense of weariness had given place to a general aching, though not with headache or chilliness. I do not think that I could have slept that night but for taking a dose of my compound phenacetin pills, the formula of which contains six grains of phenacetin, four of quinine, one of Dover's powder, and a fifth of a grain of extract of aconite, divided into two pills. The next morning I found that I had quite a sore throat, but on examination it appeared quite unlike any sore throat which I had seen, showing a general fiery redness, but without the least swelling of the parts implicated, which were the whole fauces and the tonsils. There was no sign of either suppurative or follicular tonsillitis, nor of an exudation anywhere. Some of my medical friends, who also looked into my throat, averred that they had seen nothing like it. I then had my blood examined, and the report was 24,000 leucocytes, with an unusually large proportion of polynuclears. It was evident, therefore, that I had an acute invasion by some microorganism, and the polynuclears were hastening to meet the enemy. The leucocytosis did not begin to decline till the third day: the temperature remained between 100°-101°, but the soreness in the throat grew worse and to it was soon added a general glossitis, so that my tongue completely desquamated and remained afterwards sore for three weeks.

I then looked up the literature of sore throat and found in my medical journal files a communication by Sir Felix Semon to the *British Medical Journal*, June 26, 1909, entitled "Pneumococcus of the Throat," detailing the histories of two cases of sore throat, which he published because he had not in his great experience seen anything resembling them. His description quite tallied with mine so far, except that he does not mention desquamation of the tongue. He then had their throats swabbed and the secretions examined bacteriologically, with the report of pure cultures of pneumococcus in both cases. Accordingly I had the same procedure taken with my throat secretion and the report was likewise an abundant and pure culture of pneumococcus.

As the clinical story of Sir Felix Semon's patients was not encouraging, for they were between six and seven weeks getting better, I left the city July 13 for my cottage adjoining the Wawbeek Hotel, on the Upper Saranac Lake, in the Adirondacks, for change of air. The after history of my case then became interesting. Feeling apparently better by the change I took a short mile walk and returned to the evening dinner at the hotel. Suddenly I alarmed my family by a complete paralysis of my arms so that I could not feed myself. This, however, soon passed off and I went into the reception room, where I talked some time with a friend from New York, when suddenly again I found that my legs were completely paralyzed, so that I had to be carried to the cottage and put to bed. This attack in turn did not last long, and the next morning I seemed as well as usual. Five days after I took another and longer walk, but in the evening the leg paralysis returned worse than ever, and I noticed when I was carried to bed that my tongue seemed also paralyzed so that I articulated with difficulty. The next morning again I was all over it, but had I not been a physician this experience would have badly frightened me. I reasoned, however, that I was experiencing the effects of absorption of a toxin from the throat similar to that which causes the paralysis of diphtheria, and at about the same intervals of four weeks from the primary infection; only that these attacks appeared to be more transient. It was, however, only seemingly so, for I had to be very careful afterwards in my walk and twice fell, once into a camp-fire, but fortunately during a pouring rain, so that I escaped injury. Nor have I yet wholly recovered the walking power which I had last June.

It is useless to ask why the pneumococcus attacked my throat so exclusively and did not show a sign of developing in the lungs. We now know that pneumonia is only a local manifestation of the infecting agent in the blood, which goes by the name of Fraenkel's diplococcus or pneumococcus, and which may dwell in the mouths of fully 40 per cent. of healthy persons without causing a sign of mischief; or the pneumococcus may kill without producing any local lesion whatever as shown by Flexner, Hektoen, and other competent pathologists. Why also it should be harmless in the mouth and deadly when it grows in the lungs we do not know. All we know is that it behaves very differently according to where and in what tissue it develops, causing in one patient pneumonia, in another pleurisy without pneumonia, in another peritonitis, in another both endo and pericarditis, in another otitis, and in another arthritis. From their symptoms we would not expect that these very various lesions running in each case a different clinical course were all due to one and the same cause, but so they

may be, as bacteriological investigation clearly proves.

But another important factor which enters into the action of all pathogenic microorganisms must now be taken into account. This factor is that something which we call virulence, or power to poison, and which is frequently characterized by great variability in degree.

The degree of virulence often varies with the season. One year a given epidemic is very severe in its incidence and in the number of its accompanying complications. Another year an epidemic of the same disease is much milder in both these respects. Moreover, in the same year the cases which occur during the beginning and the height of the epidemic are much more severe than the cases developing during its subsidence. Thus in one of my winter services at the Roosevelt Hospital thirty cases of epidemic cerebrospinal meningitis were admitted. Of the first sixteen all died except two; of the remaining fourteen all lived except two, the treatment throughout being the same in both classes; the only difference being that the first set were admitted during the inception of the epidemic and the second during its decline. Such facts have much bearing on statistics of therapeutics, for we should first know in what year or at what stage of the visitation the observations were made. Similar statements apply to typhoid fever. One season at the Roosevelt Hospital we had what was virtually a different typhoid fever from any preceding years, characterized by an unusual mortality, but also by a low range of temperature.

But for variety in its pathogenic powers commend us to the pneumococcus. Thus Dr. Eyre had a strain of pneumococci, of which only 20 cocci proved fatal when injected into rabbits. He also had a strain, morphologically just the same, of which 100,000 were not as quickly fatal as the 20 cocci of the first strain. Therefore, he would be an inexperienced physician who judged of the danger to his patient with pneumonia solely from the physical signs in his chest. I do not like to hear a patient with pneumonia quietly say that he is not going to get well. A gentleman once said that to me when the physical signs remained insignificant in extent for a whole week, after which they rapidly developed with the most pronounced symptoms of general toxemia.

Therefore this virulence, or power to poison, varies indefinitely among pathogenic microorganisms. In some it does not vary at all but always kills, as in hydrophobia, and almost so in tetanus. But in the others it is rarely the same for any length of time. Some toxic strains lose much of their virulence if kept for a few days, others if exposed for but a few moments to sunshine, others again, and among them the pneumococcus, if they are much exposed to fresh air. The pneumococcus, also, is very sensitive to carbolic acid. In both these respects we seem to have valuable hints for practice. But, on the other hand, we can increase the virulence of a given strain by having it grow for several generations in the bodies of animals very susceptible to it. On the contrary, the formidable variola is stripped of its virulence when passed through the body of a calf and changed into the harmless vaccinia which, however, has the same power to secure immunity from a second attack as smallpox itself. So vaccines made from pneumococci circulating in the blood are much more active than those obtained fresh from the sputum of pneumonia patients. All of which goes to show how little we know about virulence except from its effects, and hence we remain much in the same position as a man who, having never seen dynamite, guesses from its effects that it must be a very active form of gunpowder.

This organism, however, when it causes pneumonia, causes what it does not do elsewhere, namely, much trouble with the heart. Therefore, at every visit to the patient the physician should examine the heart as well as the lungs, and for this purpose should carefully note every one of the six common elements of the pulse. Three of these elements are due to the action of the heart, and three to the state of the arteries. The cardiac elements are strength (or force), rhythm, and frequency. The three arterial elements are size, whether large or small, quality, whether compressible or incompressible, ordinarily called soft or hard, and third, duration, or whether the pulse wave passes quickly or slowly under the finger. Often the only things noted about the heart are to count the frequency by the watch and feel whether the pulse is bounding or not. Of all these signs given by the pulse the most ominous is change in rhythm, whether it occurs early or late. I fully agree with Dr. Mackenzie that a change in this respect, that is, virtually an irregular pulse, presages death more than any one other symptom. Next to it comes great frequency, every rise above 125 in an adult adding to the gravity of the prognosis. Force or strength is always to be noted, but a feeble pulse, if only regular, is not so grave in its meaning as the above, because we have so many means for strengthening a merely failing heart.

I do not think that there is much difference in the effects of the pneumonic toxin on the walls of the right or of the left heart. The parenchymatous changes found post mortem in the heart correspond to like changes in the cells of the kidneys and liver and are equally present on both sides.

But the clinical accompaniments of these changes are wholly unlike on the two chambers. The left ventricle pumps its blood into the systemic arteries much easier than it does in health, the arteries are everywhere dilated as the flushed surface shows, along with the almost pathognomonic burning sensation of the skin when the physician's hand is laid upon it. The conditions confronting the right ventricle are as different as can be imagined. Besides its walls being thinner and weaker than those of the left ventricle, the obstacle of extensively hepatized lobes in front of its output is often enormous. These conditions furnish many indications in treatment, as we will soon mention, but in all cases our measures should be promptly taken, for soon the heart may show serious signs not only of being poisoned, but of failing function from exhaustion.

Moreover, the pneumococcus is fond of attacking the pericardium. As usual, the incidence of pericarditis varies in different epidemics, some authors putting it at 12 per cent. in all cases of pneumonia, and others as high as 50 per cent. It is often difficult to detect from the concomitant presence of pulmonary râles and pleural friction sounds, so that its presence may be revealed only

at autopsy. The seriousness of this complication depends on the nature of the exudate, the least serious being when this is plastic; then if it is serofibrinous, when the danger comes from its amount; but the worst is when it is purulent, for then nothing but evacuation will avail.

Both acute and chronic endocarditis can be caused by the pneumococcus, and with many it is a fatal complication. The acute form is more common in patients above thirty than at an earlier age. The aortic and pulmonary valves are oftener attacked than the mitral and tricuspid. The presence of endocarditis is often overlooked on account of the uncertainty of the signs among those due to the pulmonary or pericardial conditions, but when after a time the clinical picture is that of a continuous fever, or worse yet, if the fever be intermittent and accompanied by chills, then ultimate death is wellnigh certain.

As to the treatment of pneumonia we have reason to hope that success may come from the new science of Specific Vaccine therapy. The more I see of this recent recourse against microbic infections the more I feel convinced that its discovery is to mark a great era in medicine. Against pneumonia it has not yet proved generally successful, but this is not to be wondered at, considering our imperfect knowledge as yet both of the principles and practical applications of this new branch of therapeutics.

But while waiting for such specific measures we can do much by symtomatic treatment. One great indication is to supply the patient with all the fresh air possible. Whether the good effects here are due to the unfavorable action of oxygen on the growth of the pneumococcus itself or to the property of oxygen to strengthen muscular function is uncertain. Huxley calculated that a man would be able to move Newgate Prison if he could breathe like a flea from every part of his body instead of only through the lungs. Probably both these elements are operative. Certain it is that the chances of a pneumonia patient are better if his couch be put in a tent on the hospital's roof than down in its wards.

Another indication is to avoid as far as can be all bodily movement. In no acute disease is removal to a hospital over the rough street pavements so often fatal. I do not allow a pneumonia patient to sit up for examination. I have often seen the lips become blue on merely turning the body from one side to the other, and when this has to be done it should be as gently as possible. All this is unlike the experience with typhoid fever, when delirious patients in the third or even in the fourth week may be moved without injury.

This shows how critical the condition in pneumonia may be, owing to heart weakness, quite early in the attack, as I can now testify from the immediate muscular debility which I felt when the pneumococcus developed in my throat. The best stimulant for heart failure in pneumonia, as well as in other conditions, is camphor given hypodermically in half gram (7½ grains) doses dissolved in a syringeful of sterilized olive or almond oil, and which can be repeated in two hours if necessary. Strychnine is much inferior to camphor for this purpose. Some physicians are now giving camphor hypodermically in doses two to three times greater than as above recommended.

In many cases the onset of pneumonia is accompanied by severe pleuritic pain. This causes the breathing to be very hurried, short and shallow, and for a time the aspect of the patient is that of serious shock. At this juncture a single dose of one-fourth or one-half of a grain of morphine given hypodermically over the seat of the pain is of great service.

A different condition sometimes occurs at this early stage, which is not now treated as successfully as it was in the days of our forefathers. That condition is one of rapid congestion of the affected lung, causing acute dilatation of the right ventricle, with suffocative dyspnea. Because this state is promptly relieved by venesection much more so than by leeches or by wet cupping, our predecessors were led to bleed in pneumonia as a routine practice through the whole course of the complaint. This was a serious error, but the fact remains that nothing so soothes the patient and improves the subsequent conditions as a single venesection when the signs above given indicate it.

After an experience of half a century in the treatment of pneumonia, and after trying a great variety of remedies, I came in time to the belief that it did not make much difference what we used or did not use. Patients recovered or died just the same as they did a hundred years ago. But during the past decade I have seen reason to change my mind. Both in hospital and in consultation practice, including two severe epidemics of pneumonia, I have had a greater percentage of recoveries than before, due, as I suppose, to the use of one drug which, among other effects, changes the course of the fever so that in 70 per cent. it ends by lysis instead of by crisis. That drug is creosote carbonate in 15-grain doses given every two or three hours in a specially prepared emulsion which is so well borne by the stomach that I have known it to stay down when everything else was rejected. The extreme susceptibility of the pneumococcus to the faintest trace of carbolic acid may allow of this preparation being regarded as a true blood germicide. I have seen no injurious effect produced by it even when its absorption causes the urine to become dark. The formula for this emulsion is

℞. Gum. acaciæ ℥iv.
Aquæ ℥ivss.
f. mucilag, tunc adde
Creosoti carbonati ℥v, ♏xx.
♏. et adde:
Glycerin ℥i.
Aq. menth. pip. ad ℥viii.

S. Tablespoon = 15 grains creosote carbonate every two or three hours.

This is also my favorite prescription for pulmonary phthisis, not that I expect it to be operative against the tubercle bacillus, but against the pyogenic microorganisms whose alliance with the tubercle bacilli in the lungs is so disastrous.

70 East Fifty-fourth Street.

Transplantation and the Parathyroids.—W. Danielsen and F. Landois state that the more highly organized a tissue is the more difficult is transplantation. This applies not only to the brain and spinal cord, but also to the adrenals with their complicated structure. In contrast to these are the purely epithelial bodies, such as the mamma, ovaries, thyroid, and parathyroids. These are of histological simplicity of structure, and therefore easily transplanted.—*Medizinische Klinik.*

THE HIGH DEATH RATE FROM DIPHTHERIA IN THE UNITED STATES.*

THE PROBABLE CAUSES AND MEANS OF REDUCTION, WITH REPORT OF CASES.

By EBEN C. HILL, M.D.,

UNITED STATES ARMY.

In considering the use of diphtheria antitoxin in the treatment of diphtheria, a rather homely simile constantly recurs to me, and two of the following cases may suggest the origin of such an imaginative comparison. When treating a serious case of this disease, especially in young children, I always picture a scene in which a man's hand has been suddenly immersed in a strong acid. Imagination depicts this unfortunate individual as suffering acute pain. He is unable to remove his hand, nor can the acid be poured out. The only chance of help has been proved to depend upon the immediate use of sufficient alkali to completely neutralize the corrosive acid. The physician, standing nearby and fully appreciating the danger of the continued action of the acid is dropping into the can only a few crystals of sodium carbonate, instead of neutralizing all of the dangerous acid with several large handfuls of this alkali.

This simile is not, of course, an exact parallel with the use of toxin and antitoxin. Various views as to hemolytic action of large amounts of horse serum introduced into the human body might be considered. Also, a few cases of death have been reported as arising from the injection of this antitoxin. In these reports, however, there is no definite proof that death was the result of the serum, while there is always the supposition that the reported "paralysis of the heart" or "heart failure" resulted from the toxin, which was not quickly and sufficiently combated with antitoxin.

Long before the days of antitoxin, Flint, in his "Practice of Medicine," published in 1866, mentions heart failure in fatal diphtheria. It is difficult to attribute the deaths at that time to antitoxin. McCollom definitely and conclusively states that from a practical standpoint it has been demonstrated beyond all possibility that the heart is in no way affected by this serum. Again we note, in regard to this supposed and dreaded danger to the heart, the conclusions of White and Smith.[1] After a clinical study of 946 cases they assert that "antitoxin does not affect the heart unfavorably, but, on the other hand, its early use prevents the appearance of grave heart complications."

Some argue against the use of this serum, especially in large doses, because of its tendency to produce a serious albuminuria with a consequent fatal nephritis. Here, again, albuminuria and frequently fatal degenerative changes in the kidneys had been noted in diphtheria many years before the advent of antitoxin. Whatever may be the worth of the arguments brought forward by the few who refute the benefit of antitoxin in diphtheria or those advocating "safe dosage"—which usually means insufficient dosage—personal experience and all evidence of scientific value would urge me to risk too much rather than too little of this valuable serum.

The High Death Rate from Diphtheria as Indicated in Health Board Statistics.—The health statistics from several States indicate a high death rate from this disease. Yet the health boards are doing everything possible to combat diphtheria. Antitoxin is furnished free when needed in any quantities, is easily and quickly obtained, and there is no red tape to hinder its use in any desired amount. State laboratories quickly report whether diphtheria is present in cultures or smears. Explicit directions are given as to the use of the antitoxin. Yet we find that the mortality from this disease in the United States is many times as great as in Paris. Commissioner Eugene H. Porter of the New York State Department of Health presents the following report on this subject.[2]

Year.	1902.	1903.	1904.	1905.	1908	1909.
State of New York	37.7	39.2	38.4	28.4	28.9	27.5
City of New York	53.0	56.0	57.0	38.0	37 1	38.0
City of Paris (France) 3..	20.0	15 0	9.0	6.0	7.0	?

A glance at this table shows that the death rate from diphtheria in New York State is four times greater than in Paris, while in New York City the rate is over four times as great. Comparing Paris in 1908 with the rate per 100,000 in the registration area for the same year in several of our own States the result is far from encouraging.

YEAR 1908. RATE PER 100,000 OF MORTALITY FROM DIPHTHERIA.

Paris	7.0
Washington	35.4
Rhode Island	29.5
Colorado	28.4
Pennsylvania	27.6
New Hampshire	24.3
California	22.4
Vermont (lowest rate reported)	11.3[4]

A study of these statistics would indicate that this high death rate is not confined to any one portion of the United States. New Hampshire shows over twice as many deaths from this disease as occurred in Vermont, yet, geographically considered, the climate, environment, habits, and occupations of their people are the same. Then why should there be a higher rate in one of these States than in the other? Dr. Cressy L. Wilbur, Chief Statistician of Vital Statistics, United States Census, writes me that in the registration area of this country for the calendar year 1909 the death rate per 100,000 will be 20.4, while in the whole of France in 1907 the rate was only 9.3. The vital statistics given by Dr. Wilbur unfortunately include croup together with diphtheria. From this it is immediately apparent that our country, taken as a whole, has more than twice as many deaths from diphtheria and croup as occurred in France two years previously.

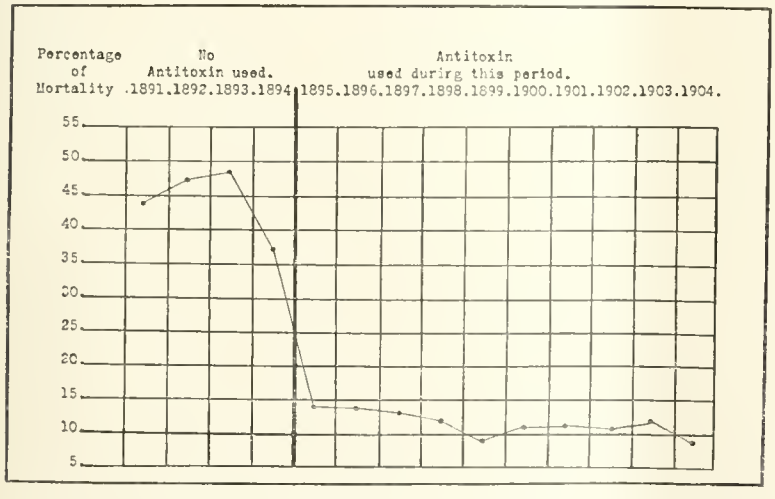
Commissioner Porter, in commenting upon the high rate in New York, states that two-thirds of all cities and villages in New York State failed to procure antitoxin, although, as he emphasizes, "all antitoxin that may be desired for immunization, prophylactic treatment, or any degree of curative administration" may be obtained without cost on a simple request to the health officer. Quite naturally when the health officer fails to obtain and keep in stock free antitoxin, and when physicians in two-thirds of the cities and villages of the State of New York do not see that their health officers have this serum, the commissioner is powerless to fight diphtheria, and the death rate assumes the proportions indicated. Nor is this condition by any means confined to New York. Many other States are having similar difficulties and other commis-

*Published with the authority of the Surgeon-General, United States Army.

sioners have been meeting the same obstacles as Dr. Porter.

The fact that so few health officers keep diphtheria antitoxin indicates either that two-thirds of the cities and towns of New York have no diphtheria—which supposition is disproved by health reports—or that the physicians do not recognize the disease until the patient has died or recovered, or else that they have no faith in antitoxin. If they do have no faith in this form of treatment, and as a consequence disregard the plainly printed directions as to dosage, and give 1,000 or 2,000 units with no succeeding treatment with the serum, their patient in the majority of cases dies of "heart failure" due, in their minds, to this serum. After such an event they have excellent and satisfactory reasons, as far as they are concerned, for never using such a dangerous drug again. A small injection of say 3,000 units of antitoxin in a serious laryngeal condition in a child can be compared to about three grains of carbonate in a pint of strong acid. That some physicians do not even read the directions for the use of this serum has been definitely proved by Dr. Porter.[5]

Behring, Ehrlich, Roux, Martin, Chaillou, and Yersin for several years previous to 1894 had been investigating the use of diphtheria antitoxin, and in 1894 they published their remarkable results. The treatment was inaugurated in France and the French physicians have learned how to use this serum fearlessly in large quantities when needed and early in the disease. The result is apparent in the statistics already given. In this country when a similar reliance has been placed on this treatment the results have been almost as encouraging. The great reduction in the mortality from diphtheria at the South Department, Boston, is shown in Chart 1.



Per cent.of mortality of diphtheria at the Boston City Hospital,proper,and at the South Department from 1891 to 1904 inclusive. Up to the year 1895 no antitoxin was used. (Dr.J.H.McCollom,Osler's Modern Medicine,Vol 2,page431.)

CHART 1.

In commenting upon the high death rate in New York State, Dr. Porter's observations are well worth serious study. "The consensus of scientific authorities of the world is to the effect that no other agent plays any rôle in the reduction of the mortality of diphtheria to be at all compared to the use of antitoxin. We can, therefore, for the purpose of this study, concentrate our attention on the use of antitoxin as the factor predominatingly reducing diphtheria mortality, and we can say at once that if the mortality of New York City or New York State exceeds the corresponding mortality of Paris the fault is most likely to be found in the extent or method in which diphtheria antitoxin is used in the corresponding localities." He then shows that the facilities for distribution of this serum are no simpler, the quality of the antitoxin is in no way inferior, and the bacilli are no more virulent in one place than in the other. Unfortunately for us, it is not difficult after such a lucid statement of facts to draw the proper conclusions as to the real causes.

Another interesting fact is that a similarly high percentage of deaths from this disease seems to prevail in private practice. In both sets of cases, however, the same deductions may be drawn. These deductions show a lack of faith in antitoxin, late diagnosis, or insufficient amounts of serum used.
